I. A Synoptic Classification of the False Scorpions or Chela-spinners, with a Report on a Cosmopolitan Collection of the same.—Part II. The Diplosphyronida (Arachnida-Chelonethida). By Joseph Conrad Chamberlin, A.B., M.A., Stanford University, California, U.S.A. 1

II. On a new Galago from South-east Africa, with a Note on *Otolicnus garnettii*, Ogilby. By Ernst Schwarz 48

III. New Genera and Species of *Phycitinæ* (Lepidoptera, *Pyralidæ*). By Sir G. F. Hampson, Bart. 50

IV. New *Derbidæ* from Sierra Leone (Homoptera Fulgoroidea). By F. Muir 81

V. On the Multiple Tumours (*Lymphocystis*) of Plaice and Flounders. By Emeritus Professor W. C. M'Intosh, M.D., D.Sc., LL.D., F.R.S., Gatty Marine Laboratory, University of St. Andrews. (Plates I.–IV.) 84

VI. Notes on Neotropical *Pselaphidæ* (Coleoptera), with Descriptions of new Species. By Frank C. Fletcher, Minneapolis, Minn., U.S.A 96

VII. The Classification of the British Carboniferous Brachiopod Subfamily *Productinæ*. By Helen M. Muir-Wood, M.Sc., F.G.S. 100

VIII. Descriptions and Records of Bees.—CXXI. By T. D. A. Cockerell, University of Colorado 108

IX. Some Remarks on *Dictyoconoides*, Nuttall (=*Conu*[illegible], Carter=*Rotalia*, Lamarck). By C. van Rijsinge, The Ha[illegible], Holland. (Plates V. & VI.) .... 11[illegible]

X. New or little-known *Tipulidæ* (Diptera).—LXIV. Australasian Species. By Charles P. Alexander, Ph.D., F.E.S., Massachusetts Agricultural College, Amherst, Massachusetts, U.S.A. .. 136

XI. Descriptions and Records of Bees.—CXXII. By T. D. A. Cockerell, University of Colorado 156

XII. Three new Species of the Genus *Helotrephes* (Hemiptera-Heteroptera). By W. E. China 164

Proceedings of the Geological Society 172–175

NUMBER 26.

XIII. Descriptions of the Type-specimens of some Carboniferous Corals of the Genera "*Diphyphyllum*," "*Stylastræa*," *Aulophyllum*, and *Chætetes*. By Stanley Smith, M.A., D.Sc., F.G.S., and W. D. Lang, M.A., Sc.D., F.R.S., F.G.S. (Plates VII. & VIII.) . 177

XIV. Thysanoptera from Africa. By Dudley Moulton, San Francisco, California 194

XV. A new Colubrine Snake from Ecuador. By H. W. Parker, B.A. 207

XVI. Some Entomostraca from Skye, with Notes on the Resting Eggs of *Cyclops pictus*, Koch. By A. G. Lowndes, M.A., F.L.S. 209

XVII. Contributions to a Study of the British Species of *Machilidæ*.—I. By H. Womersley, A.L.S., F.E.S. 217

XVIII. A new Family of Heteromerous Coleoptera (Hemipeplidæ), with Descriptions of a new Genus and a few new Species. By Gilbert J. Arrow 225

XIX. A Comparative Study of the Otoliths of the Neopterygian Fishes (*continued*). By G. Allan Frost. (Plate IX.) 231

XX. Notes on the Cephalopoda.—No. 10. On *Octopus patagonicus*, Lönnberg. By G. C. Robson, M.A. 239

XXI. Description d'un nouvel *Aseraggodes* [Pisces, *Soleidæ*] du Queensland. Par Paul Chabanaud 241

XXII. Two new Parasitic Hymenoptera. By James Waterston, D.Sc. 243

XXIII. A Third Species of the Nematode Genus *Thubunæa*. By H. A. Baylis, M.A., D.Sc. 246

XXIV. A new Alpine Grasshopper (Orthoptera, *Acrididæ*) from Mount Elgon. By B. P. Uvarov 249

Page

XXV. Descriptions of Two new Species of *Latiaxis*. By H. C. FULTON 250

XXVI. Three new Orthoptera from China. By B. P. UVAROV . 251

On Phylactolæmatous Polyzoa from Tahiti: a Correction 256

NUMBER 27.

XXVII. The *Calostylidæ*, Roemer: a Family of Rugose Corals with Perforate Septa. By STANLEY SMITH, M.A., D.Sc., F.G.S. (Plates X.-XII.) 257

XXVIII. Contributions to a Study of the British Species of *Machilidæ*.—II. A new Species of *Machilis*, Silv. (*Trigoniophthalmus*, Verhff.). By H. WOMERSLEY, A.L.S., F.E.S. 278

XXIX. Oxford University Greenland Expedition, 1928.—*Ichneumonidæ* collected by Major R. W. G. Hingston on the Oxford University Expedition to Greenland, 1928. By A. ROMAN (Stockholm) 281

XXX. A Review of the *Asaphidæ*.—Part I. By F. R. COWPER REED, Sc.D., F.G.S. 288

XXXI. A new Species of *Phenacoccus* (*Coccidæ*) from the Eastern Alps. By E. ERNEST GREEN, F.E.S. 320

XXXII. Notes on the Breeding-habits and Larval Development of *Ambystoma opacum*, Grav. By L. A. LANTZ 322

XXXIII. Some more South African *Masaridæ* (Vespoidea). By Dr. A. VON SCHULTHESS, Zürich 326

XXXIV. Notes on the Cephalopoda.—No. II. On a new Species of *Benthoctopus* from Patagonia, with Remarks on Magellanic Octopods. By G. C. ROBSON, M.A. 330

New Book:—Insects, Ticks, Mites, and Venomous Animals of Medical Importance.—Part I. Medical 335

NUMBER 28.

XXXV. Notes on "*Carcinophyllum*," Nich. & Thom., with Descriptions of Two new Species. By the Rev. T. A. RYDER, B.Sc., Ph.D., F.G.S. 337

XXXVI. An Interpretation of the Taxonomic Status of *Atya bisulcata*, Randall, and *Ortmannia henshawi*, Rathbun. By PAUL L. RADIR, University of Hawaii. (Plate XIII.) 351

XXXVII. Some *Heterakidæ* and *Oxyuridæ* [Nematoda] from Queensland. By H. A. BAYLIS, M.A., D.Sc. 354

Page

XXXVIII. Notes on the Cephalopoda.—No. 12. Observations on young Octopods obtained by the 'Dana' Expedition. By G. C. Robson, M.A. 366

XXXIX. New or little-known *Tipulidæ* (Diptera).—XLV. Australasian Species. By Charles P. Alexander, Ph.D., F.E.S., Massachusetts Agricultural College, Amherst, Massachusetts, U.S.A. 370

XL. Contributions to a Study of the British Species of *Machilidæ*.—III. The Genus *Patrobius*, Leach. By H. Womersley, A.L.S., F.E.S. 388

XLI. Oxford University Greenland Expedition, 1928.—Coleoptera from Greenland. By K. G. Blair, B.Sc., F.E.S. 394

XLII. Notes on new or less-known Holarctic *Decticinæ* (Orthoptera, *Tettigoniidæ*). By B. P. Uvarov 400

XLIII. Descriptions and Records of Bees.—CXXIII. By T. D. A. Cockerell, University of Colorado 405

XLIV. Corrections to my Paper "Studies on the Trematode Family *Heterophyidæ*." By G. Witenberg, Department of Parasitology, The Hebrew University, Jerusalem.................... 412

XLV. Thysanoptera from South Africa. By Dudley Moulton . 414

NUMBER 29.

XLVI. On some Ammonoidea from the Lower Greensand. By L. F. Spath, D.Sc., F.G.S. (Plates XIV.-XVII.).............. 417

XLVII. Exotic *Muscaridæ* (Diptera).—XXIX. By J. R. Malloch, Bureau of Biological Survey, Washington, D.C. 465

XLVIII. Descriptions of new African Moths in the British Museum Collection. By W. H. T. Tams. (Plate XVIII.) 484

XLIX. Further Studies on the Dermaptera and Orthoptera of Manchuria. By G. Bey-Bienko 493

L. The Structure of *Branchiosaurus flagrifer*, sp. n., and Further Notes on *Branchiosaurus amblystomus*, Credner. By W. F. Whittard, Ph.D., D.I.C. A.R.C.S. (Plates XIX. & XX.) 500

LI. Upper Cretaceous (chiefly Campanian and Maestrichtian) astropoda and Pelecypoda from Palestine. By Dr. Leo Picard, D.I.C., Institute of Natural History, Hebrew University, Jerusalem. Plates XXI. & XXII.) 513

LII. Preliminary Notices of Two new Snails from the Colorado Desert. By S. Stillman Berry, Redlands, California 543

LIII. Notes on certain Controversial Points of Morphology of he Abdomen and Genitalia of *Psyllidæ*. By F. Muir 545

LIV. On the Association of a Gymnoblastic Hydroid (*Zanclea rotecta*, sp. n.) with various Cheilostomatous Polyzoa from the ropical E. Pacific. By Anna B. Hastings, M.A., Ph.D. 552

LV. A new Hippoboscid Parasite (Diptera Pupipara) of the Indian Sand-Martin. By Major E. E. AUSTEN, D.S.O. 560

LVI. Second Species of the Palæarctic Genus *Podisma* (Orthoptera, *Acrididæ*) found in Assam. By B. P. UVAROV 561

LVII. The Breeding-season of 1929 in N. Cornwall. By Lt.-Col. B. H. RYVES 564

LVIII. Two new Reptiles from Southern Ecuador. By H. W. PARKER, B.A. 568

LIX. Further Considerations in regard to the Classification of the Order Thysanoptera. By RICHARD S. BAGNALL, Hon. D.Sc., F.R.S.E. 571

LX. On a new Species of Tick (*Ixodes victoriensis*, sp. n.) from Victoria, Australia. By STANLEY HIRST (Zoological Department, University of Adelaide, South Australia) 575

New Book:—I Coleotteri d'Italia (catalogo sinonimico-topografico-bibliografico) 577

Proceedings of the Geological Society 577–583

NUMBER 30.

LXI. A Synoptic Classification of the False Scorpions or Chela-spinners, with a Report on a Cosmopolitan Collection of the same.—Part II. The Diplosphyronida (Arachnida-Chelonethida). By JOSEPH CONRAD CHAMBERLIN, A.B., M.A., Stanford University, California, U.S.A. 585

LXII. A Comparative Study of the Otoliths of the Neopterygian Fishes (*concluded*). By G. ALLAN FROST. (Plate XXIII.) 621

LXIII. On the Systematic Position of the Pentatomid Genera *Parastrachia*, Distant, and *Eumenotes*, Westwood. By TEISO ESAKI, F.E.S. 627

LXIV. Notes on Palæarctic *Mantidæ* (Orthoptera). By B. P. UVAROV. (Plate XXIV.) 631

LXV. The Humble-bees captured on the Expeditions to Mt. Everest (Hymenoptera, *Bombidæ*). By O. W. RICHARDS, M.A. .. 633

LXVI. Notes on the Fiddler-crab *Uca leptodactyla*, Rathbun. By L. HARRISON MATTHEWS, M.A. (Plate XXV.) 659

LXVII. A new Species of *Leptochauliodes*, and a Note on *Chauliodes tenuis*, McLachlan (Megaloptera). By D. E. KIMMINS . 663

LXVIII. Additions to the Sponge Fauna of the Gulf of Manaar. By MAURICE BURTON, M.Sc., Assistant-Keeper, Department of Zoology, British Museum (Nat. Hist.). 665

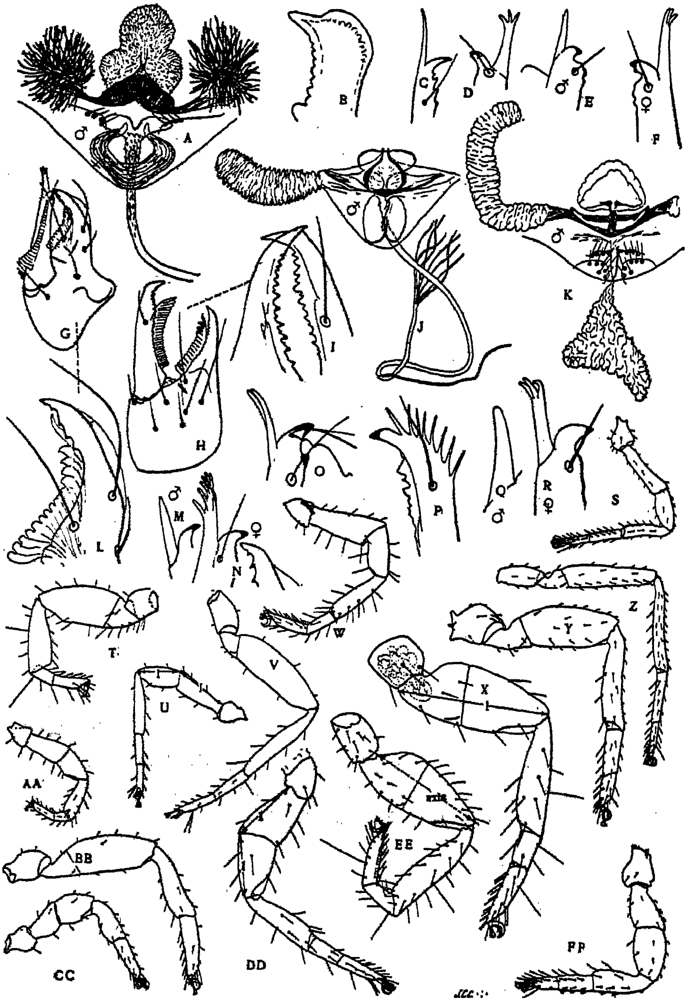
I.—*A Synoptic Classification of the False Scorpions or Chela-spinners, with a Report on a Cosmopolitan Collection of the same.*—Part II. *The Diplosphyronida* (*Arachnida-Chelonethida*). By JOSEPH CONRAD CHAMBERLIN, A.B., M.A., Stanford University, California, U.S.A.

1. INTRODUCTION.

As in the first paper of this series (Chamberlin, 1929), a number of figures (figs. 1–3) are herewith given in order to elucidate the terminology employed and to illustrate the more important systematic distinctions. They are not primarily designed to illustrate particular species; hence the form of the captions and the nature of the citations.

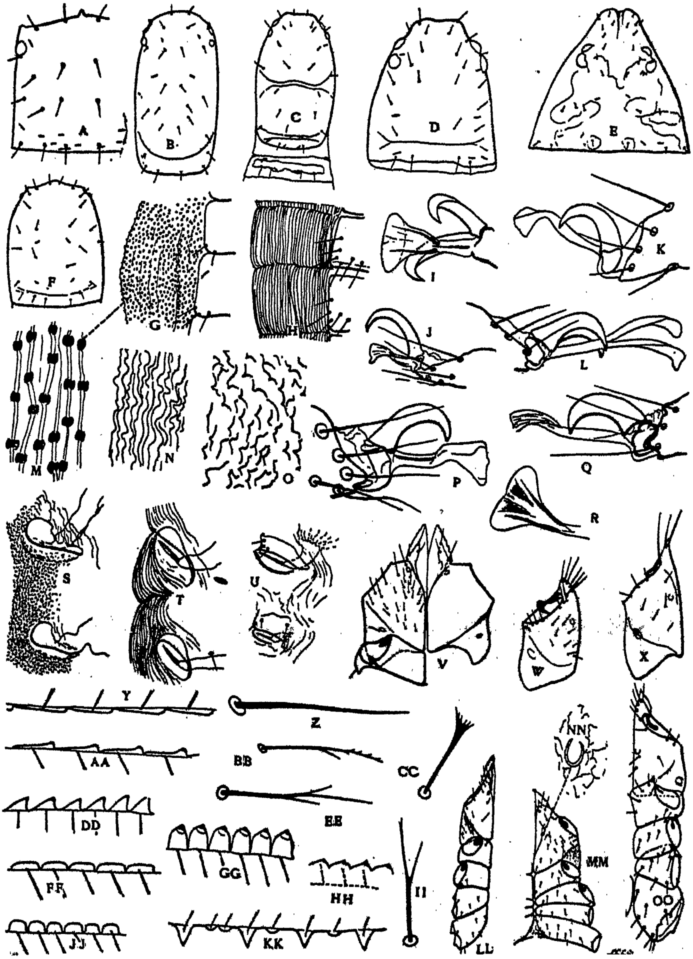
In the Diplosphyronids palpal proportions, within certain limits, are of primary importance, especially in discriminating between species. It is therefore of importance that measurements be taken in a standardized way from definite key-points. All palpal measurements must be taken as illustrated in fig. 3 X in order to yield results strictly comparable with those given in this paper. The term femur-patella which is occasionally employed in connection with

Fig. 1.



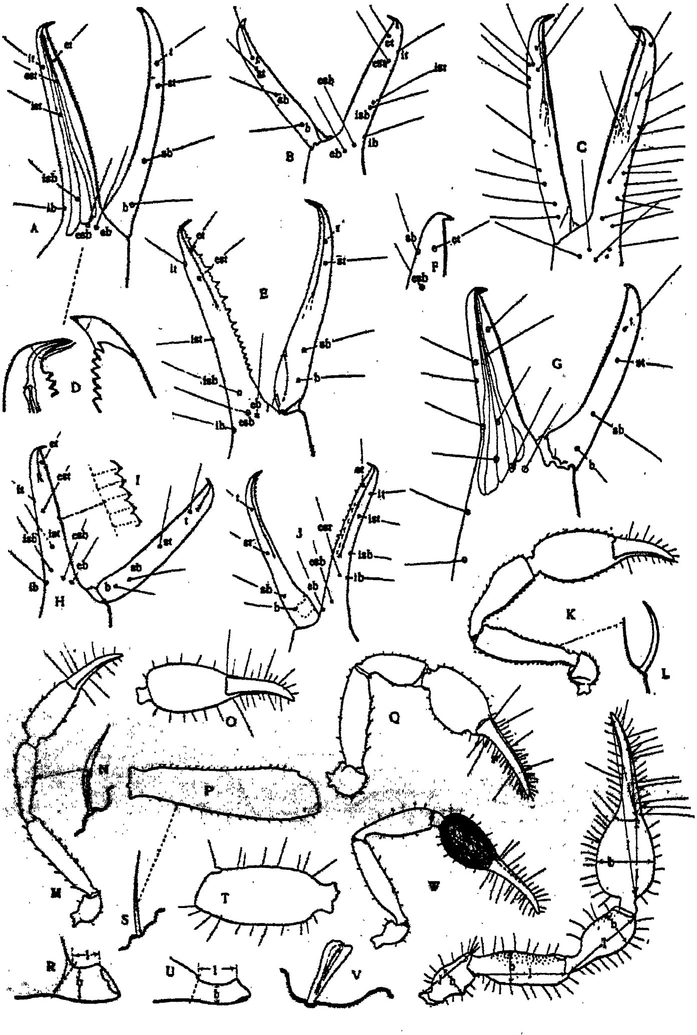
Structures of systematic significance in the Diplosphyronida. Characteristic types of male genitalia, A, J, K. Spinnerets, B, C, D, E, F, M, N, O, P, Q, R. Sexual differentation in galeate spinnerets, E, F; M, N; Q, R. Serridentate chelicera, H, I. Unilobate chelicera, G, L. Subapical lobe of unilobate chelicera, E, F, O, R. Morphological variation in leg iv., T, V, X, Y, Z, BB, EE. Morphological variation in leg i., S, U, W, AA, CC, DD, FF.

Fig. 2.



Structures of systematic significance in the Diplosphyronida. Carapacal types, A, B, C, D, E, F. Pleural membrane types, G, H. M, N, O. Empodia, I, J, K, L, P, Q, R. Spiracles, S, T, U. Maxillæ, V, W, X. Marginal teeth of chelæ (orientation, apex of fingers to left), Y, AA, DD, FF, GG, HH, JJ, KK. Subterminal setæ of tarsus, Z, BB, CC, EE, II. Coxæ, LL, MM, OO.

Fig. 3.



Structures of systematic significance in the Diplosphyronida. Chelæ showing dentition, chætotaxy, and venom-system, A, B, C, D, E, F, G, H, I, J. Various diplosphyronid palpi, K, M, Q, W, X. Palp showing mode of taking measurements, X. Tibial pedicels showing mode of taking length and breadth, R, U. Details of palpal structures, L, N, O, P, S, T, V.

leg iv. comprises both those segments taken as a unit, and is to be measured as indicated in fig. 1 X. The length so taken is not to be considered as taken along the longitudinal axis of the compound segment. This latter, as here understood, is indicated in fig. 1 EE. The relative lengths of femur and patella of leg i. are occasionally of systematic importance. Their lengths should be measured as indicated in figs. 1 U & DD. The slenderness of the pedicel of the tibial segment of the palpus is of importance in certain groups. Its length and breadth is to be taken as indicated in figs. 3 R & U.

Ordinarily variation in proportions is small. At the same time it must be recognized that where material is scanty (as is all too frequently the case) it is not possible to say whether the particular proportions stated are typical (average) or extreme. Hence considerable allowance must be made for this factor in practical work, especially in the case of species known from but one or two specimens each. In this connection it is important to keep in mind the general fact that the female, in nearly every case, is significantly larger and stouter in its proportions than the male. In my experience I know of only a few cases where the length of a palpal segment, for instance, will vary in its extremes more than 0·5–0·8 its own breadth. Where more than one specimen is available for study the extremes of proportion actually observed are given, and these are not sexually differentiated unless the variation due to this factor is considerable, or unless there is a tendency toward "overlapping" on the part of it and a closely related form. Where a series of proportions are derived from a single specimen the actually observed proportions are given, and no range of variation is indicated except rarely in keys, where this may be estimated within reasonable limits on the basis of other criteria.

The descriptive term *subequal* as employed herein in comparing relative lengths of parts means merely that the two contrasted structures are essentially equal within very small limits of variation in either direction.

Total body-length as an index of size is frequently useful. This measurement is taken from the anterior carapacal margin to the tip of the abdomen, and is from specimens which have been treated in caustic potash and mounted in Canada balsam. Alcoholic material will ordinarily measure distinctly less, about in the ratio of 9 to 10 ordinarily.

The chætotaxy of the chela is of great systematic importance. Various typical arrangements of tactile setæ

leg iv. comprises both those segments taken as a unit, and is to be measured as indicated in fig. 1 X. The length so taken is not to be considered as taken along the longitudinal axis of the compound segment. This latter, as here understood, is indicated in fig. 1 EE. The relative lengths of femur and patella of leg i. are occasionally of systematic importance. Their lengths should be measured as indicated in figs. 1 U & DD. The slenderness of the pedicel of the tibial segment of the palpus is of importance in certain groups. Its length and breadth is to be taken as indicated in figs. 3 R & U.

Ordinarily variation in proportions is small. At the same time it must be recognized that where material is scanty (as is all too frequently the case) it is not possible to say whether the particular proportions stated are typical (average) or extreme. Hence considerable allowance must be made for this factor in practical work, especially in the case of species known from but one or two specimens each. In this connection it is important to keep in mind the general fact that the female, in nearly every case, is significantly larger and stouter in its proportions than the male. In my experience I know of only a few cases where the length of a palpal segment, for instance, will vary in its extremes more than 0·5–0·8 its own breadth. Where more than one specimen is available for study the extremes of proportion actually observed are given, and these are not sexually differentiated unless the variation due to this factor is considerable, or unless there is a tendency toward "overlapping" on the part of it and a closely related form. Where a series of proportions are derived from a single specimen the actually observed proportions are given, and no range of variation is indicated except rarely in keys, where this may be estimated within reasonable limits on the basis of other criteria.

The descriptive term *subequal* as employed herein in comparing relative lengths of parts means merely that the two contrasted structures are essentially equal within very small limits of variation in either direction.

Total body-length as an index of size is frequently useful. This measurement is taken from the anterior carapacal margin to the tip of the abdomen, and is from specimens which have been treated in caustic potash and mounted in Canada balsam. Alcoholic material will ordinarily measure distinctly less, about in the ratio of 9 to 10 ordinarily.

The chætotaxy of the chela is of great systematic importance. Various typical arrangements of tactile setæ clearly illustrating the terminology employed in their connection are illustrated in figs. 3 A, B, C, E, H, J, and G. The tactile setæ are referred to individually throughout this work by the abbreviations indicated in the figures, with the exception that in the text they are always cited in capitals, thus: ET, EST, IT, etc. Their position is often indicated in terms of finger-lengths or, rather, fractions thereof. In such cases a finger-length (whether referring to fixed or movable finger) is the length of the movable finger as seen from a lateral aspect and taken from its apical tooth to its proximal exterior angle. When close together the distance between tactile setæ may be stated in terms of areolar diameters. An areolar diameter is to be understood as the diameter of the areole of one of the tactile setæ of the chela. It is a useful and reliable unit of measurement.

The nature of the venom-apparatus is of primary systematic importance, and must be ascertained with care. This can easily be done from a chela which has been dissected off, opened up, carefully cleared, and mounted on its side in Canada balsam. All the gross structures of the venom-apparatus may then be seen through the translucent chitin. Two of the possible three variants in the distribution of the venom-apparatus are found in this suborder—*i. e.*, it may be present in both fixed and movable finger (figs. 3 C, E, H, & J); or it may occur only in the fixed finger (figs. 3 A, B, D, & G).

In some groups the carapacal chætotaxy is stated as a formula (*e. g.*, 4–6 (24)). Interpreted, this particular formula indicates that the anterior margin is bordered by 4, the posterior margin by 6, while the carapace as a whole bears a total of 24 setæ.

2. SYSTEMATIC SECTION.

Section HOMOSPHYRONIDA, J. C. Chamberlin.

1929. J. C. Chamberlin, p. 78 *.

Suborder DIPLOSPHYRONIDA, J. C. Chamberlin.

1929. J. C. Chamberlin, p. 78.

Type. The family Garypidæ, Hansen.

Remarks. Cosmopolitan in distribution. Includes seven families and two superfamilies, which are characterized in the following key:—

---

* These references are to the "Bibliography," which will appear at the end of the paper.

Analytical Key to the Superfamilies and Families of the Diplosphyronida.

1. Both fore and hind legs comprising but a single tarsal segment (fig. 1 BB, CC) .. 8.

Both fore and hind legs comprising two tarsal segments each (fig. 1 T, AA; U, V; W, EE) .... 2.

2. Movable finger of chelicera clearly multidenticulate, without a true subapical lobe (fig. 1 H, I, C, P); serrula interior truly serrulate throughout and not basally laminate (fig. 1 H); subterminal seta, with few exceptions, forked or otherwise toothed or modified (fig. 2 BB, CC, EE, II); carapace generally epistomally produced (fig. 2 A, F). (Superfamily NEOBISIOIDEA, nov.) .... 3.

Movable finger of chelicera with a single (rarely secondarily subdivided (fig. 1 F, F)) subapical lobe or tooth, never multidenticulate (fig. 1 G, D, O, R); teeth of serrula interior basally fused (proximally at least) to form a membranous plate, apical teeth strongly differentiated and non-serrulate (fig. 1 L); subterminal setæ in all known cases completely simple and acute (fig. 2 Z); carapace often somewhat emarginate and rarely if ever epistomally produced (fig. 2 B, C, D, E). (Superfamily GARYPOIDEA, nov.) .... 6.

3. Venom-apparatus developed in fixed finger only, the tip of the movable finger with a definite sheath differentiated for the reception of the venedens (fig. 3 A, B, D). 4.

Venom-apparatus developed in both fixed and movable fingers, a definite sheathing device only rarely being developed on either finger (fig. 3 C, E, H, J) .... 5.

4. Pleural membrane of abdomen smoothly longitudinally plicate, never granulate (fig. 2 H); femoral articulation of leg iv. at least slightly oblique to *longitudinal axis* (fig. 1 X), and generally strongly so (almost as in fig. 1 T) .... Family SYARINIDÆ, nov., p. 38.

Pleural membrane of abdomen granulate or granulo-striate (fig. 2 G, M); femoral articulation of leg iv. truly vertical to long axis of femur-patella (fig. 1 EE) .. Family NEOBISIIDÆ, nom. nov., p. 9.

5. Pleural membrane of abdomen granulate (fig. 2 G); with the normal complement of 12 tactile setæ on fingers of chela (fig. 3 J); subterminal seta in only known case simple and acute (fig. 2 Z) .... Family HYIDÆ, nov., p. 41.

Pleural membrane of abdomen evenly longitudinally plicate (fig. 2 H); usually (except in *Bochica*) with many tactile setæ on fingers of chela, far in excess of the normal 12 (fig. 3 C); subterminal seta in all known cases more or less dentate or forked (about as in figs. 2 BB, EE, II). Family IDEORONCIDÆ, [nov., p. 42

6. Venom-apparatus developed in fixed finger only, a well-marked sheathing device developed on opposing movable finger (fig. 3 G, D); fixed finger of chela with more than the normal complement of 8 tactile setæ (11–12) in all known cases (fig. 3 G); pleural membrane smoothly plicate; carapace extremely sclerotic and very elongate (fig. 2 B) .... Family MENTHIDÆ, [nov.

Venom-apparatus developed in both fixed and movable finger, no sheathing device developed on either finger (fig. 3 H, J); chela with the normal 12 tactile setæ at most (fig. 3 H, J); pleural membrane plicate or wrinkled; carapace variously modified, but not as above (fig. 2 C, D, E). 7.

7. Pleural membrane smoothly and evenly plicate (fig. 2 H); carapace only rarely significantly triangular (fig. 2 C, D); abdomen not subovate, but with more or less parallel sides, not greatly broader than cephalothorax; vestitural setæ of palpal femur and tibia prominent (or relatively so) and always slenderly acute (fig. 3 T); stigmatic helix small, but always clearly present (fig. 2 T) .... Family OLPIIDÆ, nov.

Pleural membrane granulo-hispid or wrinkled-plicate (fig. 2 S, O, N); carapace always significantly triangular (fig. 2 E); abdomen always subovate and much broader than cephalothorax; vestitural setæ of palpal femur and tibia markedly short and inconspicuous, the shortness being especially noticeable if the setæ are acute (fig. 3 P, S; also M, N, Q, K, L, V); stigmatic helix present or absent (fig. 2 S, U) .... Family GARYPIDÆ, [Hansen.

8. With four well-developed eyes .... 9.

With two or no eyes .... Family CHELIFERIDÆ, [Hansen (old sense) *.

9. Carapace typically garypoid (fig. 2 E); abdomen without pleural plates and carapace, with neither alæ nor horn-like protuberances anterior to the eyes; legs i. and iv. strongly differentiated morphologically (fig. 1 BB, CC) .... Genus *Synsphyronus*, [nov., of the family Garypidæ.

---

* Not treated herein. This "family," or, rather, complex of families, will include the bulk of the forms to be treated in Part III. of the present series of papers.

Carapace not garypoid, with at least two prominent horn-like protuberances anterior to the eyes; with either carapacal alæ or abdominal pleural plates; legs i. and iv. of essentially the same morphological structure	Family FEÆLLIDÆ, [Ellingsen *.

Superfamily *NEOBISIOIDEA*, nov.

Type. Family Neobisiidæ, nom. nov.

Diagnosis and Remarks. Characterized in preceding key. Cosmopolitan in distribution, but, so far as present knowledge is concerned, predominantly of the Northern Hemisphere.

Family **Neobisiidæ**, nom. nov.

1894. *Obisiidæ*, Hansen, p. 231.
1906. *Obisiidæ*, With, p. 74.

Type. The genus *Neobisium*, nom. nov.

Diagnosis and Remarks. Characterized in key to families. Cosmopolitan in distribution, but predominantly Holarctic. Includes two well-marked subfamilies, which are diagnosed in the following couplet:—

Key to the Subfamilies of the Neobisiidæ.

Spinneret present or absent; if present, never galeate, but represented at most by a strongly sclerotic knob (fig. 1 B, I)	NEOBISIINÆ, p. 9.
Spinneret always present as one or more transparent galeal processes (fig. 1 C, D, P)	IDEOBISIINÆ, p. 22.

Subfamily *NEOBISIINÆ*, **nom. nov.**

1879. *Obisiinæ*, Simon, vii. p. 50.
1894. *Obisiinæ*, Hansen, p. 232.
1906. *Obisiinæ*, With, p. 75.
1928. *Obisiinæ*, Kästner, p. 9.

Type. The genus *Neobisium*, nom. nov.

Diagnosis and Remarks. Characterized in key. The substitution of the name Neobisiinæ for Obisiinæ is elucidated under the generic heading. All members of this subfamily are apparently Holarctic in distribution. The included genera and subgenera are characterized in the following analytical key :—

---

* Not dealt with in this paper. See Chamberlin, 1923 (*a*).

Key to the Genera and Subgenera of the Neobisiinæ.

1. SB and ISB absent (*i. e.*, 3 tactile setæ on movable and 7 on fixed fingers of chela); T and ST 3–5 areolar diameters apart; apical curve of maxilla with 3 border-setæ . *Microbisium*, p. 20.

T and ISB present (*i. e.*, 4 tactile setæ on movable and 8 on fixed fingers of chela); ST and SB at least 6 or 7 areolar diameters apart, SB clearly closer to B than to ST; apical curve of maxilla with 4 or 5 border-setæ (fig. 2 W) .... 2.

2. ET, EST, and IT clearly situated on distal fourth, or more usually fifth, of fixed finger; legs and palp extraordinarily slender—fingers of palps four or more times as long as breadth of chela; blind European cave-dwelling species .... *Blothrus*, p. 11.

ET, EST, and IT not all included on distal fourth or fifth of fixed finger (generally on distal third (fig. 3 A); legs and palpi not unusually slender—fingers of chela rarely (and then but little) more than twice as long as breadth of chela; non-cave forms generally with either two or four eyes (if eyes, as is rarely the case, are extremely reduced or possibly absent, separation is easily effected on the basis of preceding characters). (Genus *Neobisium*, nom. nov.) .... 3.

3. IST clearly on basal half of fixed finger of chela, forming together with EB, ESB, IB, and ISB a subbasal group of five tactile setæ; EST clearly submedian, and about as close to ISB as to ET; femur no longer than carapace (eyes four; in one species these are very weakly developed, and blind species may be expected) .... Subgenus *Parobisium*, [p. 17.

IST at least submedian and generally anterior of median; an isolated basal cluster of five setæ never developed; femur of palpus always clearly longer than carapace (eyes two or four) .... 4.

4. With two eyes; IST and ISB more or less median between the two groups of ET, EST, IT, and EB, ESB, and IB respectively, so that these two clusters of setæ are more or less connected by IST and ISB as intermediates .... Subgenus *Roncus*, [p. 12.

With four eyes; IST closely associated with EST, ET, and IT, while ISB is closely associated with the basal group of setæ, so that nearly half a finger-length of vacant space intervenes between these two groups of four tactile setæ each (fig. 3 A) ...... Subgenus *Neobisium*, [p. 13.

Genus BLOTHRUS, Schiϕdte.

1848. *Blothrus,* Schiϕdte, p. 23.

Genotype. *Blothrus spelæus,* Schiϕdte.

Remarks. As re-characterized this genus comprises a compact and apparently natural group of European cave-species. In addition to the two species specifically referred to below, the following forms almost certainly pertain to this genus as here defined :—*Obisium* (*Blothrus*) *jeannelli,* Ellingsen, from Spain; *Obisium* (*Blothrus*) *bolivari,* Nonidez, from Spain; *Obisium* (*Blothrus*) *cerberus,* Simon, from France; *Obisium* (*Blothrus*) *antrorum,* Simon, from France; *Obisium* (*Blothrus*) *torrei,* Simon, from Italy; *Obisium* (*Blothrus*) *peyerimhoffi,* Simon, from "Basses-Alpes"; *Obisium* (*Blothrus*) *breuili,* Bolivar & Pieltain, from Spain; and *Obisium* (*Blothrus*) *nonidezi,* Bolivar & Pieltain, from Spain.

"*Blothrus*" *magnus,* Ewing, and "*Blothrus*" *californicus,* Banks, do not in any wise pertain to this genus.

Blothrus spelæus, Schiϕdte.

1848. *Blothrus spelæus,* Schiϕdte, p. 23, figs.

Material examined. ♀, co-type (JC. 407.01001), loaned through the courtesy of Dr. Kai L. Henriksen. 1 ♀ (JC. 35.01001), Carniole Grotto, France; exchange from Dr. Louis Fage. The type-collection was from Adelsburg Cave.

Remarks. The French specimen, while pallid, was less so than Schiϕdte's co-type.

Blothrus abeilli, Simon.

1872. *Blothrus abeilli,* Simon, p. 224, figs.

Material examined. 1 ♀ (JC. 34.01001), from the Grotto de St. Guilhern, Herault, France. Exchange from Dr. Louis Fage.

Remarks. A more robust and less pallid species than *spelæus.*

Genus NEOBISIUM, nom. nov.

1817. *Obisium,* Leach (in part.), pp. 48–53.
1879. *Obisium,* Simon, p. 51.
1906. *Obisium,* With, p. 76.
1911. *Obisium,* Kew, p. 54.
1928. *Obisium,* Kästner, p. 10.

Genotype. *Obisium muscorum,* Leach. Designated by Simon.

Historical Identity. The genus *Obisium* was proposed by Illiger in 1798, with *Chelifer cancroides* (Linn.) as its only included species. As pointed out by Kew in 1911 (p. 54, footnote 2) this makes it a strict synonym of *Chelifer*, Geoffroy. The adoption of the name by Leach for use in connection with the species *muscorum* cannot be sustained. A new name therefore becomes necessary for the present group, which, in spite of the very evident synonymy, has gone under the name of *Obisium* ever since Leach's time. *Neobisium* is therefore proposed as a substitute. The change is regrettable, but impossible to avoid under the International Rules of Nomenclature.

Diagnosis and Remarks. Characterized in key. This is primarily a Palæarctic genus, reaching its greatest development in Europe. It has one or two eastern North American representatives. Most, if not all, of European false scorpions previously assigned to the genus *Obisium*, sensu stricto, belong here. This is probably not the case with *most* extra-European forms.

Subgenus Roncus, L. Koch.

1873. *Roncus*, L. Koch, p. 44.
1879. *Roncus*, E. Simon, p. 63.
1911. *Roncus*, Kew, p. 53.

Genotype. *Roncus lubricus*, L. Koch.

Diagnosis and Remarks. Characterized in preceding key. Two species were originally ascribed to the genus *Roncus* by Koch. One of these, *Roncus cambridgei*, is not a true *Neobisium*, but rather a member of the genus *Microcreagris*. The only species certainly referable to the subgenus are strictly European.

Neobisium (*Roncus*) *lubricus*, L. Koch.

1873. *Roncus lubricus*, L. Koch, p. 44.
1911. *Obisium* (*Roncus*) *lubricum*, L. Koch, Kew, p. 53.
1928. *Roncus lubricus*, L. Koch, Kästner, p. 10.

Material examined. 1 ♀ (JC. 27.01001), from Bona Algiers, exchange from M. Louis Fage. 1 ♀ (JC. 31.01001), from Genoa, Italy (Ellingsen's determination); exchange from British Museum.

Neobisium (*Roncus*) *abditus*, sp. n.

(Figs. 1 H, I, W, EE; figs. 2 II, OO; fig. 3 X.)

Holotype, ♂ (JC. 511.05001); allotype, ♀ (JC. 511. 05003). Paratopotypes: ♂, ♀, and ⊙ (JC. 511.05002, 511.05004–17, and 511.06001). All from Sorgono, Sardinia, where they were collected by Dr. Anton Krausse; labelled "13.4.1.2.30." All but specimens 511.05004 to 7 (2 ♂ and 2 ♀) are in collections of British Museum of Natural History; latter in author's collection.

Diagnosis. Both fixed and movable fingers, bearing 46–48 well-developed marginal teeth. Carapace subquadrate; two weakly developed eyes, which are more than a diameter from the anterior carapacal margin. Tergites with 11 or 12 and sternites with 12 or 13 marginal setæ. Palpus (fig. 3 X) robust, femur clearly granulate along its anterior face. Trochanter 2·2 to 2·3 times as long as broad; femur 2·9 to 3·1 times as long as broad, shorter than length of carapace; tibia strongly pedicellate, the pedicel measuring nearly a fourth of the total length of the segment, 2·1 to 2·3 times as long as broad; chela 2·8 to 3·1 times as long as broad; fingers slightly longer than hand. Length about 2·0 mm.

Remarks. It is possible that *abditus* represents an already described species, but this cannot be ascertained on the basis of the extant literature. The general systematic principle, that a synonym is a lesser taxonomic sin than a misdetermination, has been followed.

Subgenus Neobisium, typicus.

Genotype. *Obisium muscorum*, Leach.

Diagnosis and Remarks. Characterized in preceding key. Species clearly pertaining to this group as here defined are known from nearly the whole of Europe and middle eastern United States. A comprehensive and thorough revision of European, particularly southern European, species is badly needed.

Neobisium muscorum (Leach).

1817. *Obisium muscorum*, Leach, p. 51.
1911. *Obisium muscorum*, Leach, Kew, p. 54.
1928. *Obisium muscorum*, Leach, Kästner, p. 11.

Types. Deposited in the British Museum of Natural History, where they have been studied both by Cambridge and Kew.

Material examined. 2 ♀ (JC. 26.01001–2), Skăue, Skäralio, Sweden; exchange A. Tullgren. 1 ♀ (JC. 25.01001), Denmark; exchange Dr. Kai L. Henriksen. 1 ♀ (JC. 24.01001), Glogan, England; exchange British Museum. 1 ♂ (JC. 23.01002), "France"; exchange Dr. Louis Fage.

3 ♂, 3 ♀ (JC. 326.01001, "Bürgst bÿ Breda"; JC. 327.01001, "Hilversum"; JC. 328.01001, "Aauspoelsel raeburg"; JC. 329.01001–3, "Diener"), Holland, from decaying leaves; examined through the courtesy of Dr. A. C. Oudemans.

Neobisium incertum, sp. n. (Fig. 1 K; fig. 2 EE.)

Holotype, ♂ (JC. 511.07001); allotype, ♀ (JC. 511.07004); paratopotypes, ♂ and ♀ (JC. 511.06002–3 and 511.07005 to 15). Sorgono, Sardinia. Coll. Dr. Anton Krausse. Property of British Museum of Natural History, except paratypes, JC. 511.07005–9 (2 ♂ and 3 ♀), which are in the author's collection. Sixteen immature specimens (JC. 511.09001–16) collected at the same time and place are probably members of this species. Orginally misdetermined by myself (and so labelled in the case of the British Museum material) as *Obisium muscorum*, Leach.

Diagnosis. Fingers of chela subequal in length; marginal teeth normal on fixed finger, much reduced or obsolete on basal two-thirds of movable finger, contiguous and uniform in size. Carapace typical; espistomal process prominent. Palps robust and completely non-granulate. Trochanter normal; femur with a few scattered rounded protuberances, but otherwise smooth and polished, gradually swollen from base, attaining its greatest diameter ⅓ its length from the tip, 3·6–4·0 times as long as broad; tibia very convex on inner margin, about 2·2 times as long as broad; chela 3·5 to 3·6 times as long as broad; fingers much longer than hand and shorter than femur, which is in turn shorter than the carapace. Length 2·6–3·0 mm.

Remarks. Closely similar in many ways to *Neobisium erythrodactylum* (L. Koch). The tibia, however, is very much more convex on the inner margin, and the chela is unicolorous.

Neobisium inæqualum, sp. n.

Holotype, ♂ (JC. 13.01010); allotype, ♀ (JC. 13.01002); paratopotypes, 3 ♂ and 5 ♀ (JC. 13.01001 and 13.01003–9 and 11–12). All from "Hungary orientalis," Europe. Received from Dr. Chas. Sajo of Oersentmiklos.

Diagnosis. Fingers of chela clearly unequal in length, the movable finger being distinctly the longer; marginal teeth best developed on fixed finger, low and poorly developed on basal ¾ of movable finger, subcontiguous and of uniform size (*i. e.*, large teeth not alternating with several smaller ones). Carapace typical; epistomal process well defined, anterior eyes ½ diameter from anterior margin of carapace and ⅕ diameter from posterior pair. Palps robust, tibia and chela prominently pedicellate; non-granulate. Trochanter with rounded tubercle behind; femur not pedicellate, gradually enlarging in diameter to near its tip, about 1·5 times as long as carapace and 4·3 to 4·6 times as long as broad; tibial pedicel much longer than broad; tibia exteriorly slightly convex, interior strongly swollen medianally, with a slight concavity distally, 2·5 to 2·7 times as long as broad; chela unusually broad at base of fingers, so that latter appear to arise from a subtruncate base; pedicel as long as broad; hand egg-shaped and subequally expanded interiorly and exteriorly, 3·6 to 3·7 times as broad as long (length taken to tip of *fixed* finger); fingers clearly longer than hand, movable finger much longer than fixed finger. Tergites with about 14, sternites with about 20, marginal setæ. Length about 3·0 mm.

Remarks. Apparently related to *Neobisium elimatum* (C. Koch), which it resembles in the unequal fingers of the chela. It seems to differ therefrom in larger size, more pedicellate chela and tibia, and in the broader carapace.

Neobisium sp. indet.

Material examined. 1 ♂ (JC. 23.01001); France, exchange from M. Louis Fage.

Remarks. This species when received was erroneously determined as *muscorum* (Leach), probably by Simon. It may be *carpenteri* (Kew) or *simile* (L. Koch). Kew (1911, p. 54, footnote 2) has already shown that Simon had confused these three forms. The specimen before me is in too poor condition to permit a definite conclusion.

Neobisium carolinensis (Banks).
(Figs. 2 G, M, W; figs. 3 A, D.)

1895. *Obisium carolinensis*, Banks, p. 12.

Material examined. North Carolina: Frying Pan Gap, Mt. Pisgáh ‡, 1 (JC. 317.01001). Mt. Pisgáh ‡, 10.14.1926, 5 (JC. 315.01001–5). Headwaters, East Fork of Pisgáh River ‡, 10.14 1926, 1 (JC. 319.01001). Grandfather Mountain †, 10.12.1923, 13 (JC. 302.01001–13). Summit of Mt. Mitchell †, 10.22.1923, 25 (JC. 318.02001–25). Blowing Rock †, 10.10.1923, 3 (JC. 303.01001–3). Black Mountains †, 5 (JC. 14.01001–5), coll. R. V. Chamberlin. Montreat*, 10.16.1923, 11 (JC. 316.01001–11). Mt. Pisgáh ‡, Oct. 1923, 10 (JC. 304.01001–10). Nantahala Gap ‡, Macon.

dagger (‡) are probably more similar to *tenuis* than to the typical variety, but apparently represent true intergrades. Much further study will be required before the real status of this "species" can be ascertained.

Neobisium (?) sp. indet.

Material examined. 8, apparently all immature (JC, 307.01001–8), Quicksand, Kentucky, June 25, 1925. Coll. C. R. Crosby.

Remarks. This puzzling collection is doubtfully referred to the present genus and subgenus. In view of the apparent immaturity of all the specimens even this cannot be ascertained with certainty.

Subgenus PAROBISIUM, nov.

Orthotype. *Neobisium* (*Parobisium*) *magnum*, sp. n.

Diagnosis and Remarks. Characterized in the key.

In addition to the forms here described it is quite likely that the following species also pertain to this group:—"*Obisium japonicum,* Ellingsen; *Obisium pygmæum,* Ellingsen; and *Obisium brevifemoratum,* Ellingsen. However, if Ellingsen's opinion as to the very close relation between the last two of these three species and *Microbisium parvulum* (Banks) be sustained, it will be necessary to refer these two at least to *Microbisium,* gen. nov. A decision cannot be rendered in the absence of material.

Key to the Species of Parobisium.

1. Fingers of chela subequal in length to hand; movable finger of chela with 70 marginal teeth at most	2.
Fingers of chela clearly much longer than hand; movable finger of chela with at least 85 marginal teeth	3
2. Posterior margin of carapace with 10 marginal setæ; tergites with 16–18 marginal setæ: large species, 4·5 to 5·0 mm.; from Japan	*magnum,* sp. n.
Posterior margin of carapace with 8 marginal setæ; tergites with 10–12 marginal setæ: smaller species, 2·5 mm.; from Japan	*flexifemoratum,* sp. n.
3. Femur strongly but evenly granulate along its anterior face and 4·3 (in female) times as long as broad; palm of chelicera with eight setæ: from Oregon	*hesperum,* sp. n.
Femur at most weakly granulate along its anterior face, and 3·8 (young female) times as long as broad; palm of chelicera with six setæ: from Japan	*imperfectum,* sp. n.

Neobisium (*Parobisium*) *magnum*, sp. n.

Holotype, ♀ (JC. 389.01001). Coll. F. Silvestri, Oct. 31, 1924, at Moghi (Kyushu), Japan. No further material.

Diagnosis. Sclerotic parts smooth and polished. Fixed finger of chela with 60 marginal teeth; movable finger with 68–70. Carapace subquadrate, with blunt epistomal process; with four large eyes, the anterior pair of which is 1 diameter from the anterior carapacal margin and ⅓ diameter from the posterior pair; chætotaxy 4–10 (26). Tergites with 16–18 and sternites with 16–20 marginal setæ. Spinneret weakly if at all developed; palm of chelicera with 7 setæ. Palpi robust. Trochanter 1·8–1·9 times as long as broad; femur 3·2 times as long as broad, finely granulate along its anterior margin and broadest distally; tibia strongly pedicellate, 2·1 times as long as broad; chela 2·5 times as long as broad; fingers subequal in length to hand. Fingers gape slightly in female at least. Length of expanded female 5·0 mm.

Neobisium (*Parobisium*) *flexifemoratum*, sp. n.

Holotype, ♀ (JC. 325.01001); paratype, ♀ (JC. 325. 01002). Muchogo-o (?), Japan. Coll. June 3, 1925, by Dr. F. Silvestri.

Diagnosis. Sclerotic parts smooth except for the anterior face of the femur, which is finely but evenly granulate. Fixed finger with 49–50, movable finger with 54–56 marginal teeth. Carapace subquadrate, epistomal process obsolete; eyes greatly reduced and apparently absent in some cases (apparently absent in the holotype; four very weakly differentiated eye-spots in paratype); chætotaxy 4–8 (26). Tergites and sternites with 10–12 marginal setæ. Chelicerae more delicately formed than in *magnum*; spinneret present as a low but distinct sclerotic crest; palm with 7 setæ. Palps robust. Trochanter 1·9 times as long as broad; femur 2·6–2·7 times as long as broad, anteriorly slightly granulate, broadest basally; tibia strongly pedicellate, 2·0 times as long as broad; chela 2·7 times as long as broad; fingers subequal in length to hand. Length 2·5 mm.

Remarks. Apparently rather close to "*Obisium*" *pygmæum*, Ellingsen, from which it differs in its larger size, the presence of a clearly developed spinneret, the slightly stouter and clearly curved femur. In *pygmæum* the femur is described as "robust, with a short, robust but distinct stalk, the inner side slightly convex or nearly straight, femur on the whole nearly parallel-sided, straight, not curved."

In *flexifemoratum* it is anteriorly strongly convex and distally concave; exteriorly and basally strongly swollen, slightly concave medianally and strongly inflected distally.

Neobisium (*Parobisium*) *imperfectum*, sp. n.

Holotype, an apparently immature or young female (JC. 325.02001). From same vial of material as *flexifemoratum*. Muchigo-o (?), Japan. Coll. June 3, 1925, by Dr. F. Silvestri.

Diagnosis. Sclerotic parts uniformly smooth. Fixed finger of chela with 76, movable finger with 86 marginal teeth. Carapace much longer than broad, anteriorly somewhat produced and with a weak epistomal process; two pairs of weakly developed eyes, the anterior pair of which is nearly 2 diameters from the anterior carapacal margin and about ½ diameter from the posterior pair; chætotaxy 4–8 (26). Tergites with 11 or 12 and sternites with 14 or 15 marginal setæ. Cheliceræ slender; spinneret a longitudinal sclerotic crest as in *flexifemoratum*; palm with six setæ. Palps slender. Trochanter 2·0–2·1 times as long as broad femur weakly pedicellate and gently clavate, 3·8 times as long as broad; tibia weakly pedicellate and 2·5 times as long as broad; chela 3·4 times as long as broad; fingers much (1·2 times) longer than hand. Length 3·5 mm.

Remarks. The immaturity of the holotype is inferred from the fact that the chætotaxy of the chela is defective, SB and ISB being absent. Nevertheless, other characteristics make the generic and subgeneric placing certain. In the genus *Microbisium*, which normally possesses a reduced chætotaxy in the adult stage, the missing setæ are SB and IST; also the apical maxillary setæ number 3 instead of 4 as in the present species.

All things considered, this species seems most closely related to the American species *hesperum*, nov.

Neobisium (*Parobisium*) *hesperum*, sp. n.

Holotype, ♀ (JC. 454.01001). Cannon Beach, Oregon. Collected July 15, 1927, in the rubble beneath a log above the high-tide line, by Dr. E. C. Van Dyke.

Diagnosis. Fingers of chela with about 86–88 marginal teeth each. Carapace longer than broad, epistomal process absent; eyes 2, weakly developed, and nearly two ocular diameters from the anterior carapacal margin; chætotaxy 4–6 (24). Tergites with about 12 and sternites with 18 marginal setæ. Cheliceræ slender; spinneret present as a short, somewhat translucent, sclerotic process; palm with 8 setæ. Palps slender. Trochanter showing traces of weak granulation, straight behind, 2·7 times as long as broad; femur strongly but evenly granulate, gently clavate, and broadest distally, 4·3 times as long as broad; tibia smooth, slenderly pedicellate, and gently bilaterally convex, 3·1 times as long as broad; chela obovate basally, fingers longer than hand; chela as a whole 3·2 times as long as broad. Length 5·0 mm.

Genus Microbisium, nov.

Orthotype. *Obisium brunneum*, Hagen.

Diagnosis and Remarks. Characterized in key. Interesting because of the small sizes of the included forms and the fact that males are apparently normally absent (at least, so far as can be ascertained from non-histological studies). It is interesting to speculate as to whether or not this signifies parthenogenesis. In addition to the two species here recorded from the United States, "*Obisium*" *brevipalpe*, Redikorzev, from Kamchatka, seems almost certainly to pertain to this genus.

Ellingsen (1909, p. 220), in reporting upon a collection of material from North America, recorded *parvulum*, Banks, with the comment that it was very similar to his *brevifemoratum* and *pygmæum* from Norway and Japan respectively, and suggested further that they all possibly represented the same species. This may be true, although I am personally more inclined to believe that Ellingsen's species are valid and pertain to *Parobisium*. This point cannot be settled until the species in question are re-studied.

Two North American species definitely pertain to this interesting group. They may be separated by means of the following couplet:—

1. Fingers clearly longer than the hand (1·1 to 1·3 times as long); femur 2·9–3·2 times as long as broad .... *brunneum* (Hagen).
Fingers subequal in length to hand (0·97 to 1·03 times as long); femur 2·6 to 2·8 times as long as broad .... *parvulum* (Banks).

Microbisium brunneum (Hagen).

1869. *Obisium brunneum*, Hagen, p. 52.
1895. *Obisium brunneum*, Hagen, Banks, p. 12.

Types. Hagen's original material was from Massachusetts. It is probably preserved in the Museum of Comparative Zoology.

Determination. The determination of this form is probably correct, in spite of Hagen's insufficient original description.

Material examined. Maine: 1 immature ♀ (JC.894.01001), Presque Isle.

New York: 13 ♀ (JC. 30.01001–13), Cortland County; Labrador Pond. 1 ♀ (JC. 47.01001), Eglestons Glen, Yates County. 2 immature ♀ (JC. 51.01001 and 380.01001), Ithaca. 3 ♀ (JC. 50.01001–2 and 21.01001), Freeville. 2 ♀ (JC. 45.01001–2), Wilmington Notch, Essex County. 5 ♀ (JC. 377.01001–5), Suffexn, Ramapo Mts. 1 ♀ (JC. 385.01001), from *Woodwardia* swamp, Freeville. 5 ♀, 4 immature (JC. 381.01001–9), Cinnamon Lake, Schuyler County. 6 ♀ (JC. 298.02001–6), Sea Cliff (collected by R. V. Chamberlin). 4 ♀ (JC. 49.01001–4), sifted from moss, Ringwood, Tomkins County. 4 ♀ (JC. 378.01001–4), Montauk Point. 4 ♀ (JC. 379.01001–4), Howard. 1 young ♀ (JC. 382.01001), West Barre. 2 immature ♀ (JC. 387.01001–2), Tuxedo. 3 ♀ (very poor condition) (JC. 48.01001–3), Enfield Glen, Ithaca (determination doubtful). 1 immature (JC. 41.01001), Penn Yan (determination doubtful). 2 ♀ (JC. 383.01001–2). 6 ♀ from Heath Bog (JC. 384.01001–6), and 3 ♀ (one with discal mass of 13 normally attached eggs) (JC. 396.01001–3), McLean.

Missouri: 4 ♀ (JC. 33.01001–4), Columbia.

Ohio: 4 ♀ (JC. 404.01001–4), "southern part of state."

Virginia: 1 immature (JC. 400·01001), Alberta (determination doubtful).

Washington, D.C.: 4 apparently immature (JC. 332.01001–4), coll. H. C. Barber (determination doubtful; Crosby material).

Georgia: 2 very young (JC. 43.01001–2), Billy's Island, Okefinokee Swamp (determination doubtful).

Locality unknown (presumably eastern United States): 1 specimen (JC. 29.01001), from type-collection of *Obisium parvulum*, Banks, and labelled "co-type," proves to be the present species. 3 ♀ (JC. 405.01001–3).

Unless otherwise indicated, Dr. C. R. Crosby was the collector of the foregoing material. Specimens in Cornell University and author's collections.

Remarks. Occasionally found in company with *parvulum*, from which it is readily separated by the characters given in the key.

Microbisium parvulum (Banks).

1895. *Obisium parvulum*, Banks, p. 12.
1909. *Obisium parvulum*, Banks, Ellingsen, p. 220.

Types. Deposited in the collections of the Museum of Comparative Zoology. Type-locality unknown. Banks suggests Florida as the likely source. From other considerations (of relative distribution) I believe that somewhere in the middle north-east or west is more likely. A so-called co-type of this species (JC. 29.01001), which I have had the privilege of examining, proves to be a typical specimen of *brunneum* (Hagen). In the absence of the balance of Banks's original material, it is impossible to say whether his species will fall as a synonym or not. But since specimens are available which clearly fit his description of *parvulum* and differ from typical *brunneum*, it seems likely that his type-material contained representatives of both species.

Material examined. North Carolina: 3 ♀ and 1 immature (JC. 333.01001–4), Mt. Pisgah (3000 feet elevation), collected 10.19.1923 by C. R. Crosby.

New York: 2 ♀ (JC. 433.02001–2); 1 ♀ (JC. 52.01001), Ithaca (Fall Creek), collected 7.30.1909 by R. V. Chamberlin. 6 ♀ (JC. 396.02001–6), 5.16.1925, and 1 ♀ (JC. 386.01001), in "Heath bog," 5.30.1921, collected by C. R. Crosby, McLean.

Minnesota: 3 ♀ (JC. 395.01001–2 & 395.02001), collected June 22 and July 17, 1924, respectively, by F. C. Fletcher (Crosby-Cornell Collection), Lake Minnetonka.

Colorado: 1 ♀ (JC. 87.01001), from "surface soil or pine duff beneath douglas fir," and 1 ♀ (JC. 89.01001), from "under scrub-oak chapparal in almost pure gravel"; both lots collected by Dr. E. W. Goldsmith from near Alpine Laboratory, Engleman Canyon, Manitou.

Utah: 17 ♀ (JC. 6.01001–17), collected by author and others from damp soil beneath decaying lawn-grass clippings; in small cavities in the soil; city lot near Liberty Park, Salt Lake City.

Material in author's and Cornell University Collections.

Remarks. The Utah and Colorado material seems typical in every way.

Subfamily *IDEOBISIINÆ*, nov.

1891. *Pseudobisiidæ*, L. Balzan, p. 504.
1906. *Pseudobisiinæ*, Hansen, C. With, p. 77.

Type. Genus *Ideobisium*, Balzan.

Diagnosis and Remarks. Characterized in key. Includes three well-marked genera, which are diagnosed in the key. The geographic range of the subfamily as a whole is cosmopolitan, but predominantly northern. The old subfamily name Pseudobisiinæ is untenable, since there is no genus *Pseudobisium*.

Analytical Key to the Genera of the Ideobisiinæ.

1. Maxillaris apicalis acute, with two slender apical setæ (fig. 2 X); T, ST, and SB of movable finger submedianally clustered and scarcely or not at all a single areolar diameter apart	*Ideobisium*, Balzan, p. 36.
Maxillaris apicalis strongly rounded, short, with 3–5 apical setæ (fig. 2 W); chætotaxy of movable finger of chela not as above	2.
2. Spinneret a row of 8–10 stylet-like galeæ (fig. 1 P); setæ large and conspicuous, there being 20–22 marginal tergal setæ; no tactile setæ on distal third of fingers	*Halobisium*, gen. nov., [p. 35.
Spinneret a single simple or branched galea; setæ inconspicuous, there being at most about 12 marginal tergal setæ; at least one or two tactile setæ situated on distal third of fingers (fig. 3 B)........................	*Microcreagris*, Balzan, [p. 23.

Genus MICROCREAGRIS, L. Balzan.

1891. *Microcreagris*, L. Balzan, p. 543.

Type. *Microcreagris gigas*, L. Balzan.

Remarks. As originally defined, *Microcreagris* merged imperceptibly into *Ideobisium*. As here delimited it is a compact and homogeneous group, which includes not only all those species previously described under its head, but most of those described under *Ideobisium* as well. It is evidently a large genus. Seventeen species, most of which are undescribed, are represented in collections now before me.

The genus seems to be truly Holarctic, reaching its maximum development in China, Japan, and the Pacific coast of North America.

The following artificial key will facilitate specific determinations. It is obviously incomplete :—

Key to certain Species of Microcreagris.

1. Fingers "about" * the same length as the hand	2.
Fingers either longer or shorter than hand	3.

---

* It cannot be clearly ascertained from the literature just how the relative lengths of finger and hand were taken. It is possible that remeasurement, on the basis of the method here followed, would alter the ratio given in either direction—hence this precaution.

2. Giant species, 7·1 mm. long: femur of palps smooth; cheliceræ longer than carapace, which possesses a strongly developed epistomal process; with 4 prominent eyes: from China ...... *gigas*, L. Balzan, p. 28.
Small species, 2·5 mm. long: femur of palps strongly granulate; cheliceræ much shorter than carapace, which possesses a moderately developed epistomal process; with 2 eyes: from Europe .... *cambridgei* (L. Koch), [p. 30.
3. Fingers of chela clearly shorter than hand (if small European or giant Chinese species, see also couplet 2 *). 4.
Fingers of chela clearly longer than hand (if small European or giant Chinese species, see also couplet 2 *) ...... 7.
4. Large species (6·5 mm.): from California. *magnum* (Banks), p. 28.
Smaller species (5·0 mm. or less): from the Orient .... 5.
5. Fingers of chela longer than carapace; chela thrice as long as broad: from Tibet .... *kaznakovi*, Redikorzev, [p. 28.
Fingers of chela shorter than carapace; chela distinctly less than three times as long as broad: from China or Japan .... 6.
6. Tibia shorter than hand; fingers no longer than breadth of chela; with 4 apical maxillary setæ; marginal teeth of fingers of chela 35–40 .... *brevidigitata*, sp. n., p. 26.
Tibia longer than hand; fingers much longer than breadth of chela; with 5 apical maxillary setæ; marginal teeth of fingers of chela 65–75 .... *silvestrii*, sp. n., p. 27.
7. Palps at least slightly (generally quite conspicuously) granulate, especially along the anterior femoral margin .. 12.
Palps quite smooth, including the anterior femoral margin .... 8.
8. Femur subclavate, attaining its greatest diameter at least slightly anterior of median: western American species.. 9.
Femur clearly broadest on its basal half, becoming thereafter gradually and progressively attenuate distally: eastern American or Oriental species. 10.
9. IT clearly posterior to and hence posteriorly oblique with ET (fig. 3 F); apical maxillary setæ normally 3 (rarely reduced to 2): small species, 3·5 mm. long .... *cingara*, sp. n., p. 29.

---

* It cannot be clearly ascertained from the literature just how the relative lengths of finger and hand were taken It is possible that remeasurement, on the basis of the method here followed, would alter the ratio given in either direction—hence this precaution.

IT even with ET, both the same distance from apex of finger; apical maxillary setæ normally 5 (may be reduced to 4 in immature specimens): large species, 5–6 mm. long .... *sequoiæ*, sp. n., p. 28.

10. IT clearly anterior to ET, and hence anteriorly oblique therewith; apical maxillary setæ 5 .... *japonica*, Ellingsen, p. 28.

IT clearly posterior to ET, and hence posteriorly oblique therewith (fig. 3 F, B, etc.); apical maxillary setæ 3 or 4 .... 11.

11. T and ST only 2 or 3 areolar diameters apart; ST situated ⅓ closer to T than SB; femur 2·4 to 2·7 times as long as broad and anteriorly very finely granulate, as may readily be seen by close inspection: small Oriental species, about 2·0 mm. long .... *formosana*, Ellingsen, p. 30.

T and ST 4 or 5 areolar diameters apart; ST situated only slightly nearer T than SB; femur 3·0–3·1 times as long as broad and completely smooth: larger eastern United States species, about 3·0 mm. long .... *atlantica*, sp. n., p. 29.

12. Femur strongly pedicellate and non-clavate, broadest just beyond pedicel. *formosana*, Ellingsen *, p. 30.

Femur weakly pedicellate and clearly clavate in general appearance, attaining its greatest breadth submedially or distad thereof .... 13.

13. Posterior margin of carapace with 8 or 9 setæ: Oriental species .... 14.

Posterior margin of carapace with 6 border-setæ: western American species .... 15.

14. Tibia stoutly pedicellate, the pedicel itself no longer than its own greatest width (fig. 3 R); trochanter 1·9 to 2·0 times as long as broad .... *orientalis*, sp. n., p. 34.

---

* *Formosana*, Ellingsen, may be readily separated from *cambridgei* (L. Koch), which it much resembles in certain respects, by means of the following couplet (see also couplet 2):—

12 *a*. IT clearly closer to EST than ET, being much more distant from the apex of the finger than the former (fig. 3 B); 2 eyes; femur prominently granulate: from England .... *cambridgei* (L. Koch), p. 30.

IT closer to ET than EST, being scarcely more distant from apex of finger than the former (fig. 3 F); 4 weak eyes; femur inconspicuously granulate: Oriental species .... *formosana*, Ellingsen, p. 30.

	Tibia slenderly pedicellate, the pedicel itself clearly much longer than its own greatest width (fig. 3 U); trochanter 2·2–2·3 times as long as broad	*lampra*, sp. n., p. 34.
15.	Tibia elongate, 3 or more times as long as broad in male and 2·8 times or more as long as broad in female	16.
	Tibia plainly stouter than indicated above—no more than 2·7 times as long as broad in male, and correspondingly stouter in female	17.
16.	Trochanter with two small but distinct, widely separated, rounded eminences behind; femur of male 4·3 to 4·5 times as long as broad; tibia of male 3·4 to 3·5 times as long as broad; length of male 3·0–3·5 mm.	*hespera*, sp. n., p. 31.
	Trochanter with inconspicuous irregularities behind, but not as in *hespera*; femur of male at most 4·0–4·1 times as long as broad; tibia of male at most 2·9–3·0 times as long as broad; male 2·0–2·5 mm. long	*duncani*, sp. n., p. 33.
17.	Tibia clearly longer than fingers of chela; EB and ESB arising from summits of small rounded tubercles: from eastern United States	*rufulum* (Banks), p. 30.
	Tibia barely equal to or shorter than fingers of chela; EB and ESB not arising from the summits of tubercles: from western United States	18.
18.	Fingers of chela subequal to tibia in length	19.
	Fingers of chela clearly longer than tibia.	20.
19.	Chela of female 3·0–3·1 times as long as broad; tibia 2·5 times as long as broad; carapace clearly longer than tibia; female 3·5 mm. long	*thermophila*, sp. n., p. 32.
	Chela of male 3·8 times as long as broad; tibia 2·7 times as long as broad; carapace and tibia subequal in length; male 1·9–2·0 mm. long	*lauræ*, sp. n., p. 32.
20.	Femur 3·6 times as long as broad; tibia 2·3–2·5 times as long as broad; chela 2·8–2·9 times as long as broad; male about 3·0 mm. long	*phyllisæ*, sp. n., p. 31.
	Femur 3·1–3·7 times as long as broad; tibia 2·6–2·8 times as long as broad; chela 3·3–3·7 times as long as broad; 2·0–2·8 mm. long	*macilentum* (Simon), p. 31.

Microcreagris brevidigitata, sp. n.

Holotype, ♀ (JC. 390.01001), Mte. Kirishima, Japan. Coll. ix.20.1924 by Dr. Silvestri.

Diagnosis. Movable finger of chela with 40–42 and fixed finger with 33 or 34 marginal teeth. Carapace little if any longer than broad, with two pairs of weakly developed eyes, of which the anterior pair is about ¼ ocular diameter from the posterior pair and 1·5–2·0 diameters from the anterior carapacal margin, which bears a weakly developed epistomal process; chætotaxy 4–10 (28). Apical maxillary setæ 4. Tergites with 13 or 14 and sternites with 16–18 marginal setæ; no discal setæ on sternites. Palps short and robust and nearly smooth. Trochanter 1·8 times as long as broad; femur attaining its greatest diameter ⅓ length from base, weakly granulate along its anterior margin, and 2·4 times as long as broad; tibia stoutly pedicellate, the pedicel itself as broad as long, 1·9 times as long as broad; chela 2·3 times as long as broad; hand 1·7 times as long as the short stubby fingers, which are no longer at most than breadth of hand. Length 3·5 mm.

Microcreagris silvestrii, sp. n.

Holotype, ♂ (JC. 399.01001), Ychyhan (China ?); coll. x.24.1925. Paratopotypes, 4 ♂, same collection data (JC. 399.01002–5).

Diagnosis. Chela with 80–85 marginal teeth on movable and 67–73 on fixed finger. Carapace quadrate, with two pairs of well-developed eyes, the anterior pair of which is ¾ ocular diameter removed from the posterior pair and over a diameter from the anterior carapacal margin, which bears a weakly developed epistomal process; chætotaxy 6–9 (32–33). Apical maxillary setæ 5. Tergites with 14 or 15 and sternites with a similar number of marginal setæ; sternites without differentiated discal setæ. Palps moderately stout and largely smooth. Trochanter with well-developed conical protuberance behind, 1·7 times as long as broad; femur broadest submedianally, completely smooth except for a few scattered rounded tubercles, 3·0–3·1 times as long as broad; tibia stoutly pedicellate, pedicel itself as long as broad, 2·1–2·2 times as long as broad; chela 2·4–2·6 times as long as broad; fingers clearly shorter than hand, but much longer than its breadth. Length of male about 4·0 mm.

Remarks. The holotype shows a very interesting abnormality in the abdominal segmentation. The tergites are completely normal in appearance, but the left half of the seventh sternite only is present. Medianally the fragmentary sternite "pinches out," and the right side possesses no trace of the missing part.

Microcreagris magnum (Banks).

1909. *Ideobisium magnum*, Banks, p. 306.

Remarks. I have not seen material of this species, which is undoubtedly a member of the present genus. If Banks's description is correct, it is the only American member of the genus which possesses chelal fingers which are shorter than the hand.

Microcreagris kaznakovi, Redikorzev.

1918. *Ideobisium* (*Microcreagris*) *kaznakovi*, Redikorzev, p. 97, figs.

Remarks. I have not seen material of this species. Redikorzev's description is adequate. It should be easily determined on the basis of the characters given in the key.

Microcreagris gigas, L. Balzan.

1891. *Microcreagris gigas*, L. Bazan, p. 544.

Remarks. I have not seen material of this species. It is interesting principally as the type of the genus. Its large size and enormous cheliceræ should render it readily recognizable.

Microcreagris japonica, Ellingsen. (Fig. 2 BB.)

1907. *Microcreagris gigas*, var. *japonica*, Ellingsen, p. 7.

Material examined. 1 ♂ (JC. 517.01001), coll. by S. Akiyama at Idzu, Japan, June 1910. Deposited in British Museum of Natural History. 1 ♂ (JC. 388,01001), Chofu, China. Coll. xi.11.1924, by Dr. F. Silvestri.

Remarks. Although Ellingsen's characterization of this form is brief, I believe the determination to be correct. I cannot agree with Ellingsen that the species is a "form" of *gigas*.

Microcreagris sequoiæ, sp. n.

Holotype, ♂ (JC. 570.01001), sifted, together with an immature specimen (JC. 570.01002), from rotting leaves in a grove of redwoods (*Sequoia sempervirens*), by author, ix.7.1927; Muir Woods, Marin County, California.

Additional Material. A badly damaged female (JC. 22.01001), collected by Dr. F. R. Blaisdell, vi.16.1922, at Willow Creek, Humboldt County, California, probably pertains to this species.

Diagnosis. Chela with about 65 marginal teeth on movable and 70 on fixed fingers. Carapace subquadrate, with two pairs of well-developed eyes, the anterior pair of which is about ⅓ ocular diameters from the posterior pair and about 1 diameter from the anterior carapacal margin, which bears a well-developed epistomal process; chætotaxy 4–6 (24). Apical maxillary setæ 5. Tergites with about 12 and sternites with about 16 marginal setæ; sternites 7 and 8 with a weakly differentiated median pair of discal setæ. Palps robust and non-granulate. Trochanter with one or two weak apical protuberances behind, 1·7 times as long as broad; femur smoothly clavate, broadest distally, 3·4 times as long as broad; tibia stoutly pedicellate, the pedicel no longer than broad, 2·3 times as long as broad; chela thrice as long as broad; fingers slightly but distinctly longer than hand. Large species, ♂ 5 mm. long.

Microcreagris cingara, sp. n. (Fig. 2 GG; figs. 3 F, R.)

Holotype, ♂ (JC. 245.02001); allotype, ♀ (JC.245.02002); paratopotypes, 2 ♀, 1 immature (JC. 245.02005–7). All collected iii.19.1924, by Dr. Vasco Tanner at St. George, Utah.

Additional Material. 1 ♀ (JC. 436.01001), coll. xi.24.1927 by D. T. Jones as Springfield, Oregon, seems to pertain to this species. The carapace is scarcely if at all longer than broad, and the femur is broadest somewhat more basally than in the type. Otherwise typical.

Diagnosis. Chela with 55–60 marginal teeth on movable and 60 on fixed finger. Carapace a little longer than broad, with two well-developed pairs of eyes, the anterior pair of which is ½ ocular diameters from the posterior pair and 1 diameter from the anterior carapacal margin, which bears a moderately developed epistomal process; chætotaxy 4–6 (24–26). Apical maxillary setæ 2 or 3. Tergites with 12 and sternites with about 15–16 marginal setæ; sternites 7 and 8 with a weakly differentiated pair of median discal setæ. Palps robust and non-granulate. Trochanter almost or quite evenly convex behind, 1·6–1·8 times as long as broad; femur broadest distally, clavate in appearance, and 3·0–3·3 times as long as broad; tibia stoutly pedicellate, the pedicel no longer than broad, 2·1–2·2 times as long as broad; chela 2·7–2·8 times as long as broad; fingers clearly longer than hand. Length 3·5–4·0 mm.

Microcreagris atlantica, sp. n.

Holotype, ♂ (JC. 434.01001); allotype, ♀ (JC. 434.01002). Both from an unlabelled vial included in a general collection of material from the eastern United States, as collected by Dr. R. V. Chamberlin. Paratype, 1 ♀ (JC. 262.01001), "probably from Asheville," North Carolina. Coll. R. V. Chamberlin.

Diagnosis. Chela with 51–54 marginal teeth on movable and 45–48 on fixed fingers. Carapace clearly longer than broad, with two pairs of eyes, the anterior pair of which is less than $\frac{1}{2}$ ocular diameter from the posterior pair and 1 diameter from the anterior carapacal margin, which possesses a well-developed epistomal process; chætotaxy 4–5 or 6 (26). Apical maxillary setæ 4. Tergites with about 12 and sternites with the same number of marginal setæ; sternites without discal setæ. Palpus medium in build and completely smooth. Trochanter with a small rounded protuberance behind, 1·7–1·9 times as long as broad; femur broadest about medianally, clearly pedicellate, and 3·0–3·1 times as long as broad; tibia with robust pedicel, which is clearly as broad as long, 2·1 to 2·3 times as long as broad; chela rather strongly swollen on inner face, 2·8 to 2·9 times as long as broad; fingers very clearly longer than hand. Length 2·3 to 2·8 mm.

Microcreagris formosana, Ellingsen.

1912 (*b*). *Microcreagris granulata*, var. *formosana*, Ellingsen, p. 127.

Material examined. 2 ♀ (JC. 558.01001–2). Labelled simply "*Microcreagris granulata*, Ellingsen, var." The source of this material is not now known to me, but it was received in exchange. This is almost surely a part of Ellingsen's original collection of some 50 specimens from Takao, Formosa.

1 ♀ (JC. 550.02001), coll. C. F. Baker. Mt. Makiling, Luzon, Philippine Islands.

Remarks. The characters given in the key to the species will amply supplement Ellingsen's scanty original data. I feel quite sure that the determination is correct.

Microcreagris cambridgei (L. Koch).

1873. *Roncus cambridgei*, L. Koch, p. 45.
1911. *Obisium* (*Ideoroncus*) *cambridgei*, Koch, Kew, p. 53.

Material examined. A single ♀ in poor condition (JC. 28.01001), from Devon, England, is at hand. Exchange from the British Museum of Natural History.

Microcreagris rufulum (Banks).

1891. *Obisium rufulum*, Banks, p. 166.
1895. *Ideobisium rufulum* (Banks), Banks, p. 11.

Material examined. 2 ♂, 1 ♀, and 1 ⊙ (JC. 7.01001–4), coll. iv.18 (year unknown), at Glen Sligoe, near Washington, D.C; 2 ♂ (JC. 296.02001–2), from Washington, D.C.; 19 ♂ and ♀ (JC. 3.02001–18), Falls Church, Virginia; 1 ♀ (X. 406.01001), v. 1 (year unknown), Great Falls, Virginia. All except first lot from Dr. R. V. Chamberlin.

Microcreagris hespera, sp. n. (Fig. 3 U.)

Holotype, ♂ (JC. 451.01001), Pepperwood Creek, near mouth of Gualala River, Mendocino County, California; coll. viii.24.1928, by B. C. Cain. Paratype, ♂ (JC. 15.01001), Berkeley, California; coll. Dietrich; loan from Cornell University..

Diagnosis. Chela with 79 teeth on movable and 77 on fixed finger. Carapace longer than broad; apparently completely eyeless; without epistomal process; chætotaxy 4–6 (22). Tergites with about 10, sternites with about 12 border-setæ; sternites 7–9 with a submedian pair of clearly differentiated discal setæ. Maxilla with 3 apical setæ. Palpi extremely long and slender, and conspicuously but evenly granulate. Trochanter with an anterior and posterior rounded tubercle behind, 2·6 times as long as broad; femur attenuate, broadest near tip, 4·4 times as long as broad; tibia with a long and slender pedicel, clearly much longer than broad, 3·4 times as long as broad; chela attenuate, fingers greatly longer than hand and nearly four (3·9) times as long as broad. Length of male 3·5 mm.

Microcreagris macilentum (E. Simon).

1878. *Obisium macilentum*, E. Simon, p. 157.

Material examined. ♂ (JC. 529.01001), 9 ♂ and ♀ (JC. 529.01003–11), and 1 ♂ and 3 ♀ (JC. 54.01001–4). All from Claremont, California. Other collection-data unknown.

Remarks. This determination is probably correct. Dr. Louis Fage has kindly compared one of my specimens (JC. 54.01002) with the type, and verifies my conclusion.

Microcreagris phyllisæ, sp. n.

Holotype, ♂ (JC. 376.01001), Coronado, California, on beach in kelp; coll. by Dr. F. R. Blaisdell, i.19.1928. Paratype, ♂ (JC. 9.01001), Eaton's Cave, Los Angeles County, California, May 1913; from R. V. Chamberlin.

Diagnosis. Movable finger of chela with 52 and fixed finger with a similar number of marginal teeth. Carapace scarcely longer than broad, with two pairs of well-developed eyes, the anterior pair of which is about ⅓ ocular diameter from the posterior pair and a scant diameter from the anterior carapacal margin; epistomal process well developed; chætotaxy 4–6 (26). Apical maxillary setæ 4–5. Tergites with 12 and sternites with 16 marginal setæ; sternites 6–8 with a submedian pair of clearly differentiated discal setæ. Palps slender and clearly granulate. Trochanter with median rounded protuberance behind, granulate, and 2·1 times as long as broad; femur evenly granulate, gradually enlarged from pedicel to near tip, and 3·5–3·6 times as long as broad; tibia with slender pedicel, which is clearly longer than broad, granulate, and 2·4–2·5 times as long as broad; chela slender, 3·0–3·2 times as long as broad; fingers much longer than hand. Length of male 3·2 mm.

Remarks. Named for Phyllis Chamberlin.

Microcreagris thermophila, sp. n.

Holotype, ♀ (JC. 547.01001); paratype, ♀ (JC. 547.01002). Under stones on desert hillside, Box Springs Grade, near Riverside, California. Coll. xi.1925, by the author.

Diagnosis. Movable finger of chela with 53–56 and fixed finger with 44 marginal teeth. Carapace plainly somewhat longer than broad and bearing a single pair of weakly developed eyes, which are clearly more than their own diameter from the anterior carapacal margin; epistomal process vestigial; chætotaxy 4–6 (22). Apical maxillary setæ 4. Tergites with 13–14 and sternites with 14 or 15 marginal setæ; sternites 6–8 with a submedian pair of discal setæ. Palps of slender granulate type. Trochanter granulate, with one or two small posterior protuberances, 2·1–2·2 times as long as broad; femur granulate, gently clavate, and broadest distally, 3·4–3·6 times as long as broad; tibia smooth, with a slender pedicel which is slightly longer than broad, 2·4–2·5 times as long as broad; chela swollen much more greatly on inner than outer face, much as in *macilentum*, 3·0–3·1 times as long as broad; fingers much longer than hand. Length of female 2·8–3·5 mm.

Microcreagris lauræ, sp. n.

Holotype, ♂ (JC. 42.01001), Berkeley, California, i.1920. Cornell University Collection.

Diagnosis. Marginal teeth of chela not ascertainable from type. Carapace much longer than broad, plainly narrowed; with two pairs of weakly developed eyes, the anterior pair of which is more than half an ocular diameter from the posterior pair and 1·5 diameters from the anterior carapacal margin; no epistomal process; chætotaxy 4–6 (22). Apical maxillary setæ 4. Tergites with 12 and sternites with 15 or 16 marginal setæ; sternites without definitely differentiated discal setæ. Palps of slender granulate type. Trochanter granulate, with a couple of weak protuberances behind, 2·4 times as long as broad; femur prominently granulate, gently clavate, and broadest distally, 3·8 times as long as broad; tibia granulate, with pedicel which is clearly longer than broad, 2·7 times as long as broad; chela flattened on outer and swollen on inner face, as in *macilentum*, plainly somewhat granulate, 3·6 times as long as broad; fingers much longer than hand. Length of male 1·6 mm.

Remarks. Named for Laura Anne Chamberlin.

Microcreagris duncani, sp. n. (Fig. 3 B.)

Holotype, ♂ (JC. 5.01001); allotype, ♀ (JC. 5.01002); paratypes, 22 ♂ and ♀ (JC. 5.01003–24). Collected by C. D. Duncan and the author, i.1.1923, under stones in damp soil on serpentine outcrop, Jasper Ridge, San Mateo County, California.

Additional Material. 2 ♂ (JC. 56.01001–2), Alhambra Valley, Contra Costa County, California, xii.29 (year unknown). Collections of California Academy of Sciences. 1 ♀ (JC. 46.01001), collected by Dr. F. E. Blaisdell, iv.16.1922, San Antonio Canyon, Alameda County, California.

Diagnosis. Movable finger of chela with 57–64 and fixed finger with 55–63 marginal teeth. Carapace plainly longer than broad, with two pairs of weakly developed eyes, the anterior pair of which is ½ diameter from the posterior pair and 1 diameter from the anterior carapacal margin, which is devoid of an epistomal process; chætotaxy 4–6 (24). Apical maxillary setæ 4. Tergites with 11–12 and sternites with about 16 marginal setæ; sternites without clearly differentiated discal setæ. Palps of slender granulate type. Trochanter almost parallel-sided, with one or two small protuberances behind, 2·4–2·6 times as long as broad; femur granulate, broadest subdistally, 3·7–4·2 times as long as broad; tibia with slender pedicel, which is clearly longer than broad, granulate, 2·8–3·1 times as long as broad; chela slender, somewhat granulate near fingers at least, 3·8–4·2 times as long as broad; fingers much longer than hand. Length 2·2–2·5 mm.

Remarks. Close to *lauræ*, sp. n. The Alameda County specimen has a stouter chela than typical material (3·5 times as long as broad). Named for Carl Dudley Duncan.

Microcreagris lampra, sp. n.

Holotype, ♀ (JC. 398.01001); paratype, ♀ (JC. 398. 01002). Collected ix.27.1924, by Dr. F. Silvestri at Kusang (China ?).

Diagnosis. Movable finger with 81 and fixed finger with 85 marginal teeth. Carapace subquadrate, epistomal process weakly developed; with two pairs of strongly developed eyes, the anterior pair of which is $\frac{1}{3}$ ocular diameters from the posterior pair and 1 diameter from the anterior carapacal margin; chætotaxy 6–8 or 9 (about 30). Apical maxillary setæ 5. Tergites with about 12, sternites with 16 marginal setæ; sternites without discal migrants. Palps of a robust granulate type. Trochanter weakly granulate, distally widened, with a distinct protuberance behind and 1·9–2·1 times as long as broad; femur broadest distally, granulate along its inner face, 3·4–3·6 times as long as broad; tibia weakly granulate, with a stout pedicel which is no longer than broad, 2·3 times as long as broad; chela smooth, equally convex anteriorly and posteriorly, 3·0–3·1 times as long as broad; fingers much longer than hand. Length of ♀ about 5·5 mm.

Remarks. Very closely related to *orientalis*, sp. n. The most striking points of difference are indicated in the key.

Microcreagris orientalis, sp. n.

Holotype, ♀ (JC. 397.01001), coll. ii.22.1925, by Dr. F. Silvestri at Lookay (China ?).

Diagnosis. Movable finger with 80, fixed finger with 87 marginal teeth. Carapace subquadrate, with vestigial epistomal process and two pairs of weakly developed eyes, the anterior pair of which is $\frac{1}{3}$ to $\frac{1}{2}$ ocular diameter from posterior pair and 1·5 diameters from the anterior carapacal margin; chætotaxy 6–8 (28). Apical maxillary setæ 5. Tergites with 12 and sternites with about 15 marginal setæ; sternites without discal migrants. Palps moderately robust and granulate. Trochanter weakly granulate, with protuberances behind, 2·2 to 2·3 times as long as broad; femur moderately granulate, especially anteriorly, broadest distally, 3·6 times as long as broad; tibia with slender pedicel which is clearly longer than broad; weakly granulate, especially along its anterior margin, 2·4 times as long as broad; chela evenly swollen on either face, smooth, 3·3 times as long as broad; fingers much longer than hand. Length of ♀ 4·0 mm.

Remarks. Very close to *lampra*, sp. n. Most important differences are indicated in the key.

Microcreagris sp. uncertain or indeterminable.

Material examined. The following specimens are without question members of the genus, but because of immaturity or mutilation are specifically indeterminable.

2 ⊙ (JC. 44.01001–2), collected in moss, Portland, Oregon, iii.28.1921, by Prof. E. O. Essig. Pertains to the medium-fingered smooth-palped group of species.

2 ♀ (badly crushed) (JC. 55.01001–2), Claremont, California (from Hilton). Pertains to the medium-fingered smooth-palped group of species.

2 ♀ (JC. 8.01001–2) (badly crushed and mutilated), coll. x.4.1908, at Kendric, Idaho. Pertains to the long-fingered granulate-palped group of species. Stanford University Collection.

4 ⊙, JC. 440·02001, 441.01001, 443.02001, and 444.01001). Coll. during June and July of 1928 by Prof. Martha W. Shackleford; one taken in sweeping herbs, one in dead-leaf litter in stand of *Alnus oregona,* two in moss on ground in Douglas fir-forest, Friday Harbour, San Juan Island, Washington State. These specimens quite likely pertain to *cingara,* sp. n.

Genus Halobisium, nov.

Orthotype. *Ideobisium orientale*, Redikorzev.

Diagnosis. Adequately characterized in key. Known from the coast of California; Commander Islands (off coast of Kamchatka) and "Siberia."

Halobisium orientale (Redikorzev). (Fig. 1 P.)

1917. *Ideobisium orientale,* Redikorzev, p. 98, figs. (published 1922).

Material examined. 53 specimens: ♂, ♀, and ⊙ (JC. 1.01001–45 and 2 A to 2 H). All collected under boards, logs, and other "drift" on Salicornia flats, Palo Alto Salt-Marshes (shores of San Francisco Bay), California, in situations where flooding at high-tides occurs. First lot collected by author, fall of 1921. Lot 2 collected by O. Elton Sette in April 1921.

1 ♀ (JC. 185.01001), from under board about five feet above water-level in Salicornia salt-marshes east of Palo Alto, ix.6.1925. A number of additional specimens (JC. 285.01001–5) from the same locality were taken on the under side of large logs in company with isopods, amphipods, and a few marine worms, v.27.1928. 1 ♀ (JC. 324.01001), labelled "Claremont, California," collected by C. F. Baker

(the locality Claremont is certainly an error; the specimen most certainly came from a semi-marine habitat, possibly Laguna Beach). 1 ♂ and 1 ♀ (JC. 431.01001–2), Commander Islands, Siberia; material received from Dr. R. V. Chamberlin. All material at present in author's collection.

Remarks. Redikorzev had four specimens from an unknown locality and one specimen from "Province de l'Oussourie du Sud : lac Reineke."

The determination seems certain. Redikorzev's description and figures are good, and the material from Siberia falls well within the limits of variation found in specimens from San Francisco Bay.

Genus IDEOBISIUM, L. Balzan.

1891. *Ideobisium*, L. Balzan, p. 539.

Genotype. *Ideobisium crassimanum*, L. Balzan.

Diagnosis and Remarks. Adequately characterized in the key. The four widely distributed species known to me may be separated by means of the following key. I have not seen material of the genotype, but there is little doubt but what it and the three others with which it is here associated are congeneric:—

1. Fingers clearly shorter than breadth of hand; hand 1·7 times as long as fingers (femur 2·3 times as long as broad; tibia 1·7 times as long as broad): from Venezuela .... *crassimanum*, Balzan, [p. 37.

Fingers clearly longer than breadth of hand; hand 1·4 or less times as long as fingers .... 2.

2. Subterminal seta suddenly expanded distally into a broad spatulate tip, which is terminally denticulate (fig. 2 CC): from the Seychelles Islands .... *seychellesensis*, sp. n., [p. 38.

Subterminal seta acute, with fine marginal denticulations or short branches (fig. 2 BB) .... 3.

3. Fingers 1·1–1·2 times as long as breadth of chela; hand 1·1–1·3 times as long as fingers; posterior margin of carapace with six setæ; length 1·5–1·8 mm.: from Lesser Antilles .... *balzanii*, With, p. 37.

Fingers 1·2–1·3 times as long as breadth of chela; hand 1·0–1·1 times as long as fingers; posterior margin of carapace with 7 or 8 setæ; length 2·2–2·8 mm.: from New Zealand .... *peregrinum*, sp. n., [p. 37.

Ideobisium crassimanum, L. Balzan.

1891. *Ideobisium crassimanum*, L. Balzan, p. 542.

Remarks. I have not seen material of this species.

Ideobisium balzanii, With.

1905. *Ideobisium balzanii*, C. With, p. 131, figs.

Material examined. ♂ (JC. 12.01001), from St. Vincent, Lesser Antilles, West Indies. Exchange from British Museum. This is apparently one of With's paratypes. In poor condition.

Ideobisium peregrinum, sp. n.

Holotype, ♂ (JC. 94.02001), coll. Robert W. Grimmet, xi.20.1920, under log in beech forest, Days Bay, Wellington, New Zealand; allotype, ♀ (JC. 96.01001), coll. in leaf-mould by Robert W. Grimmet near Wellington, New Zealand; paratype, immature ♀ (JC. 460.01001), from Kingston, Lake Watipu, New Zealand, Hogg coll. Property of British Museum of Natural History.

Diagnosis. Fixed finger of chela with 31–35 and movable finger with 37–40 marginal teeth. Carapace about quadrate, slightly longer than broad; very broad rounded epistomal process present; with two pairs of weakly developed eyes, the anterior pair of which is ½ diameter from the posterior pair and over 1 diameter from the anterior carapacal margin; chætotaxy 4–7 or 8 (22–24). Galea stylet-like and gently recurved. Subterminal setæ with many laterally situated short branches, not at all clavate or spatulate. Palps of typical robust form; non-granulate. Trochanter concave behind, 1·6 times as long as broad; femur strongly pedicellate and nearly as strongly swollen anteriorly as posteriorly, broadest slightly proximad of median, 2·5 to 2·7 times as long as broad; tibia stoutly pedicellate and bilaterally expanded, 1·9–2·0 times as long as broad; chela strongly and bilaterally swollen beyond the sharply differentiated pedicel, 2·5 to 2·8 times as long as broad; fingers distinctly shorter than hand. Length of ♂ 2·2, ♀ 2·8 mm.

Remarks. In spite of the great geographical discontinuity of their ranges, this species is remarkably close to *balzanii*, With.

Ideobisium seychellesensis, sp. n.
(Figs. 1 X, DD; fig. 2 CC.)

Holotype, probably ♀ (JC. 510.01001). Coll. by the Seychelles Expedition of 1908, on the 'Felicete.' Only the type known.

Diagnosis. Appearance typical. Fixed finger of chela with 33, movable finger with 40 marginal teeth. Carapace and abdominal structures unknown (the body of the type-specimen having accidentally been lost in course of preparation for study). Spinneret a gently recurved stylet. Subterminal seta distally flaring into a terminally incised spatula (fig. 2 CC). Palps of typical robust non-granulate form. Trochanter concave behind, 1·8 times as long as broad; femur much more swollen posteriorly than anteriorly, broadest proximad of median, 2·6 times as long as broad; tibia strongly pedicellate and bilaterally swollen, 1·9 times as long as broad; chela more strongly swollen on inner than outer face, 2·3 times as long as broad; fingers clearly a little longer than hand. A small species, but, owing to loss of body previously noted, an exact measurement is unavailable.

Family **Syarinidæ**, nov.

Type. The genus *Syarinus*, J. C. Chamberlin.

Diagnosis and Remarks. Characterized in key. Comprises two distinct subfamilies and three genera, all known thus far only from the western United States. They may be separated by means of the following key:—

Key to Subfamilies and Genera of the Syarinidæ.

I. Subterminal setæ completely simple and acute; femoral articulation of leg iv. plainly oblique (about as in fig. 1 T); galeate spinneret present. (Subfamily SYARININÆ, nov.) .... 2.

Subterminal setæ plainly toothed or dentate; femoral articulation of leg iv. only weakly oblique (about as in fig. 1 X); galea completely absent. (Subfamily CHITRINÆ, nov.) .... *Chitra*, gen. nov.

2. Marginal teeth of movable finger of chela clearly contiguous; T of movable finger present and nearly contiguous with ST; with a single pair of weakly developed eyes or eye-spots .... *Syarinus*, [J. C. Chamberlin.

Marginal teeth of movable finger of chela clearly and widely spaced; T of movable finger absent; with 4 distinct eyes...... *Hyarinus*, [J. C. Chamberlin.

Subfamily *SYARININÆ*, nov.

Type. The genus *Syarinus*, J. C. Chamberlin.

Diagnosis and Remarks. Characterized in key.

Genus SYARINUS, J. C. Chamberlin.

1925. *Syarinus*, J. C. Chamberlin, p. 329.

Orthotype. *Ideoroncus obscurus*, Banks.

Remarks. The genus includes two, and possibly three, species from the western half of the United States.

Syarinus obscurus (Banks).

1893. *Ideoroncus obscurus*, Banks, p. 66.
1925. *Syarinus obscurus* (Banks), J. C. Chamberlin, p. 330.

Material examined. In addition to the material reported by the author in the note cited above, the following material is at hand :—Two specimens (JC. 570.02001–2), sifted from the dead leaves beneath redwoods in Muir Woods, Marin Co., California, coll. by author, ix.7.1927 ; 3 specimens (JC. 438.01001–3), coll. by A. M. Woodbury, viii.29.1927, in Yellowstone National Park, Wyoming.

Remarks. The male sof this species apparently have a very membranous genital apparatus, and in consequence are very difficult to recognize.

The following couplet will permit its easy separation from *granulatus*, sp. n., its closest relative :—

1. Femur completely smooth and non-granulate; femur 2·6 to 2·8 times as long as broad; chela 2·8–3·0 times as long as broad.............. *obscurus* (Banks).
   Femur evenly and distinctly granulate; femur 3·0–3·3 times as long as broad; chela 3·5 times as long as broad......................... *granulatus*, sp. n.

Syarinus granulatus, sp. n. (Fig. 2 H.)

Holotype, ♂ (JC. 86.01001); allotype, ♀ (JC. 88.01001); paratypes, ♂ (JC. 83.01001) and ♀, 2 (JC. 82.01001–2). All collected by Dr. E. W. Goldsmith in surface-soil or pine-duff beneath Douglas fir-trees, Engleman Canyon, near Alpine Laboratory at Manitou, Colorado.

Diagnosis. Movable finger with 49–50 and fixed finger with 39–44 marginal teeth. Carapace longer than broad, with two weakly developed eyes or eye-spots about an ocular diameter from the anterior carapacal margin; with about 12 marginal setæ along its posterior border as in *obscurus*. Tergites and sternites with 16 and 20 border-setæ respectively, as in *obscurus*. Palps relatively slender, trochanter and femur finely and evenly granulate. Trochanter scarcely swollen behind, 2·5 times as long as broad; femur pedicellate, evenly rounded behind, slightly and gradually expanded anteriorly, and with a distinct but gentle distal concavity, broadest about medianally, 3·0–3·3 times as long as broad; tibia with stout pedicel, almost bilaterally swollen, as long as carapace and 2·7 times as long as broad; chela strongly pedicellate and somewhat more strongly swollen on its outer than inner face, side of hand nearly parallel, 3·5 times as long as broad; fingers curved and much shorter than the hand, which is itself about the same length as the tibia. Length 2·8–3·0 mm.

Remarks. Very distinct from, although clearly related to, *obscurus*, Banks.

The species described by Banks as *Ideobisium tibiale* from Colorado is almost certainly a member of the present genus. If so, it is probably rather close to the present species.

Genus Hyarinus, J. C. Chamberlin.

1925. *Hyarinus*, J. C. Chamberlin, p. 327.

Orthotype. *Hyarinus hesperus*, J. C. Chamberlin.

Remarks. This genus is known only from the type-species, which has not been taken since its original discovery. The type-locality of the type-species is Santa Barbara, California (see Chamberlin, *l. c.* p. 328).

Subfamily *Chitrinæ*, nov.

Type. The genus *Chitra*, nov.

Diagnosis and Remarks. Characterized in key. Includes only the monotypic type-genus, which is known thus far only from California.

Genus Chitra, nov.

Orthotype. *Chitra cala*, sp. n.

Diagnosis and Remarks. In addition to the characters indicated in the key, the males of this genus possess a peculiar median sensorium (presumably) on the sixth sternite. It consists of a circular membranous area surrounding a median sclerotic patch and bordered by acute setæ.

The genus is known only from the orthotype, which is a rare Californian species.

Chitra cala, sp. n. (Figs. 2 X, JJ.)

Holotype, ♂ (JC. 276.01001), sifted from leaf-mould and grass-roots taken from under a willow-tree on the banks of San Francisquito Creek, Stanford University Campus, California, collected by author xii.17.1927. Paratypes, 1 ♂, 3 ♀ (JC. 42.01001–4), January 1920, Berkeley, California. The holotype and one ♀ paratype are in the author's collection; the balance of the material is in the Cornell University Collection.

Diagnosis. Marginal teeth of fingers of chela well developed anteriorly and posteriorly and on both fingers, 42–50 marginal teeth on fixed and 48–55 on movable finger. Carapace distinctly longer than broad, with two pairs of weakly developed eyes and no epistomal process; chætotaxy 6–8 (28). Tergites and sternites with 18–20 marginal setæ. Palps slender, all segments but trochanter with definite areas of fine but even granulation. Trochanter with small protuberance behind, 2·1 to 2·2 times as long as broad; femur weakly pedicellate, attaining its greatest breadth subbasally, and maintaining it thereafter almost to the tip, sides subparallel, 3·5–3·8 times as long as broad; tibia slenderly pedicellate, pedicel longer than broad, thereafter bilaterally swollen and distinctly narrowed distally, 2·3–2·4 times as long as broad; chela pedicellate, bilaterally expanded, 3·0–3·2 times as long as broad; fingers much longer than hand and also tibia. Length 2·2 to 3·0 mm.

Family **Hyidæ**, nov.

Type. The genus *Hya*, nov.

Diagnosis and Remarks. Characterized in preceding key. Represented by a single rare genus, confined, so far as present knowledge permits us to say, to the Philippine Islands. Most closely related to the Ideoroncidæ.

Genus HYA, nov.

Orthotype. *Hya heterodonta*, sp. n.

Diagnosis and Remarks. In addition to the characters noted in the diagnosis of the family, the following characters are probably of generic extent:—

Heterodentate, marginal teeth of fingers of chela unequally developed. Chelicerae normal, with a simple stylet-like galea, lamina exterior absent. Eyes four. Femoral articulation of legs iii. and iv. slightly but clearly oblique to the long axis of the compound segment. Femur of legs i. and ii. much longer than patella. Subterminal seta completely simple and unbranched.

Only the orthotype is known.

Hya heterodonta, sp. n. (Fig. 2 KK ; fig. 3 E.)

Holotype, ♂ (JC. 550.04003); allotype, ♀ (JC. 550.04002); paratypes, 7 ♂ and ♀ (JC. 503 A, 550.04001, and 550.04004–8). Mt. Makiling, Luzon, Philippine Islands. C. F. Baker Collection. Four paratypes are deposited in the United States National Museum.

Diagnosis. Chela slender and conspicuously toothed ; fixed finger with 16 acute teeth, which anteriorly are widely spaced ; between the antero-median of these spaced teeth occur from one to three slightly spaced short and rounded smaller teeth (fig. 2 KK) ; movable finger with marginal teeth very weakly developed are nearly absent, apparently of the contiguous type. Carapace slightly broader than long ; without an epistomal process ; with four well-defined eyes, the anterior pair of which is about an ocular diameter from the anterior carapacal margin ; chætotaxy 4–2 (14). Tergites i. and ii. weakly sclerotized, chætotaxy 4 : 4 : 8 : 8 : 8 : 8. Sternites each with about five marginal setæ. Cheliceræ with 6 setæ on palm ; galea very slender and needle-like. Palps slender and smooth. Trochanter excavated behind, calyciform, 2·1–2·2 times as long as broad ; femur curved, broadest distad of median, 3·8–4·1 times as long as broad ; tibia stoutly pedicellate, the pedicel shading gradually into the rather slender tibia proper ; tibia equal to or longer than carapace, scarcely broader than femur, and 2·4–2·8 times as long as broad ; chela slightly expanded exteriorly at pedicel, then nearly straight to tip of fingers, interiorly greatly swollen and convex, 3·2–3·3 times as long as broad ; fingers much longer than hand or tibia, and nearly as long as femur. Length 1·2–1·4 mm.

Family Ideoroncidæ, nov.

Type. The genus *Ideoroncus*, L. Balzan.

Diagnosis and Remarks. Characterized in key. Representatives occur in southern Asia, North America, and South America. The five genera and two subfamilies here recognized may be separated by means of the following key :—

Analytical Key to the Subfamilies and Genera of the Ideoroncidæ.

1. Chela with the normal 12 tactile setæ, of which IB is subbasally situated on the dorsum of the hand (empodia distinctly shorter than tarsal claws (as in fig. 2 J)). (Subfamily Bochicinæ, nov.)	*Bochica*, gen. nov., [p. 43.
Chela with far in excess of the normal 12 tactile setæ (fig. 3 C) (empodia shorter or longer than tarsal claws). (Subfamily Ideoroncinæ, nov.)	2.
2. Dorsal quadrangle of tactile setæ of hand of chela large, the distance between the exterior setæ clearly greater than the basal width of the movable finger (the posterior pair of dorsal tactile setæ clearly median): South American genus	*Ideoroncus*, L. Balzan, [p. 44.
Dorsal quadrangle of tactile setæ of chela small and compact, the distance between the two exterior setæ being distinctly less than the basal width of the movable finger: North American or Asiatic forms (if North American, the two basal setæ of the dorsal quadrangle are clearly distad of median on the hand)	3.
3. Empodium clearly longer than and extending far beyond the tarsal claws (fig. 2 P); empodium simple or divided	4.
Empodium clearly shorter than the tarsal claws and always undivided (fig. 2 J) ..	*Dhanus*, gen. nov., [p. 47.
4. Empodia clearly bifurcate (fig. 2 L); tergites and sternites entire; lamina exterior absent	*Albiorix*, gen. nov., [p. 44.
Empodia simple and undivided (fig. 2 Q, R); tergites and sternites clearly divided into two lateral scutæ each; small lamina exterior present......................	*Shravana*, gen. nov., p. 48.

Subfamily *Bochicinæ*, nov.

Type. *Bochica*, gen. nov.

Diagnosis and Remarks. Characterized in key. Known from the monotypic type-genus, which is West Indian.

Genus Bochica, nov.

Orthotype. *Ideoroncus withi*, J. C. Chamberlin.

Diagnosis and Remarks. Characterized in key. The plainly plicate abdominal pleural membrane associates this rare genus with the Ideoroncidæ rather than the Hyidæ, which it suggests in the normality of the chætotaxy of the chela.

Bochica withi (J. C. Chamberlin).

1905. *Ideoroncus mexicanus*, Banks (misdetermination), C. With, p. 127.
1923 (*b*). *Ideoroncus withi*, J. C. Chamberlin, p. 359 (nom. nov., species described as *Ideoroncus mexicanus*, Banks, by With (*l. c.*)).

Material examined. Through the courtesy of Dr. Susan Finnegan of the British Museum, I have been privileged to examine the specimen upon which With's generally excellent description was based. This specimen, ♀ (JC. 486.01001), has been designated the holotype of the species. It was collected "near Chantilly" (Windward Islands) at 800 feet elevation in fermenting "cocoa-husks."

Subfamily IDEORONCINÆ, nov.

Type. The genus *Ideoroncus*, Balzan.

Diagnosis and Remarks. Characterized, together with its included genera, in the preceding key.

Genus IDEORONCUS, L. Balzan.

1890. *Ideoroncus*, L. Balzan, p. 444.

Genotype. *Ideoroncus pallidus*, L. Balzan.

Remarks. I have been unable to secure material of Balzan's type-species. As a result, the genus must be left inadequately defined. The genus is certainly a valid one, and the only question is as to its relationship to the other genera of the family. In addition to the orthotype it is quite possible that *Ideoroncus gracilis*, Balzan, belongs here.

Ideoroncus pallidus, Balzan.

1890. *Ideoroncus pallidus*, L. Balzan, p. 444, figs.
1910. *Ideoroncus pallidus*, L. Balzan, Ellingsen, p. 395.

Remarks. Balzan's material of this species was from Paraguay. Ellingsen later recorded it from near Rio de Janeiro in Brazil.

Genus ALBIORIX, nov.

Orthotype. *Ideoroncus mexicanus*, Banks.

Diagnosis and Remarks. Adequately characterized in the preceding key. It may be noted that the chela is always considerably broader than deep. The three species of the genus here recognized may be separated by means of the following key:—

1. Margin of fixed finger of chela conspicuously serrate, due to the close-set retro-conical teeth (fig. 2 DD); the movable finger is similarly dentate near its tip .... 2.

Marginal teeth of both fixed and movable fingers largely obsolete, these teeth being extremely broad at the base, with the very low tooth-cap or apex almost vertically above their respective posterior limits (figs. 2 Y, AA); superficially "toothless," except for the venedens .... *edentatus*, sp. n., p. 46.

2. Fixed finger with a total of 30–32 teeth, of which the posterior ones are low and indistinct, being evident only by the spaced projecting tooth-caps (fig. 2 AA); movable finger with 6–8 rather rounded teeth anteriorly, the balance being vestigial; femur and carapace subequal in length: small species, 1·7–2·0 mm. long.. *parvidentatus*, sp. n., [p. 45.

Fixed finger with a total of 48–50 teeth, of which the posteriormost are reduced, but not so conspicuously so as in *parvidentatus*; movable finger with 14–20 pretty well marked acute teeth near tip of finger: larger species, 2·3–2·6 mm. long . *mexicanus* (Banks), [p. 45.

Albiorix mexicanus (Banks). (Figs. 2 F, DD.)

1898. *Ideoroncus mexicanus*, Banks, p. 289.
1923 (*b*). *Ideoroncus mexicanus*, Banks, J. C. Chamberlin, p. 359, figs.

Neotype, ♀ (JC. 370.01001), Las Animas Bay, Lower California, Mexico. The original holotype was destroyed in the San Francisco earthquake of 1906, and hence the foregoing designation, which was made in 1923 by the author. Banks's material was from San Miguel de Horcasitas, Sonora, Mexico.

Material examined. Mexico: Gulf of California; San Esteban Island, ♀ (JC. 110.01001). San Marcos Island, ♀ (JC. 371.01001). California: ♀ (JC. 375.02001), El Centro, coll. xii.12.1927, by Dr. F. R. Blaisdell Utah: ♀ (JC. 245.01001), St. George, coll. iii.19.1924 by Dr. V. M. Tanner. 8 ♂ and ♀ (JC. 449.01001-8, "Straight Wash," coll. iv.20.1928, by "W. J. G." ♂ (JC. 450.01001), Straight Canyon, San Rafael Desert, iv.20.1928, coll. by A. M. Woodbury. ♀ (JC. 437.01001), Bluff, coll. iv.16.1928, by "W. J. G." Last three collections received from Dr. R. V. Chamberlin.

Remarks. The Utah specimens seem to be quite typical.

Albiorix parvidentatus, sp. n.

Holotype, ♂ (JC. 535.02001), Palm Canyon, Riverside

County, California. Coll. by the author under a stone on a desert hillside, iv.5.1925.

Other Material examined. A dead and immature female (JC. 547.01003), together with its cast skin, was taken in a silken moulting-capsule from the underside of a stone on a desert hillside near Riverside, California. Coll. xi.26.1925 by the author.

Diagnosis. Fingers of chela with conspicuous retro-conical teeth anteriorly on both fixed and movable fingers; 30–32 in all on fixed finger, becoming progressively reduced and inconspicuous basally; movable finger with six or seven distal teeth, which are clearly defined but scarcely acute; posterior to these the teeth are very much reduced or wholly absent. Carapace typical, about same length as, or shorter than, the femur or the fingers of the palps. Palps slender, all segments more or less evenly granulate. Trochanter with distinct protuberance behind, as in *mexicanus*, 2·2–2·3 times as long as broad; femur of typical form, 4·0–4·2 times as long as broad; tibia normal, very slightly broader than femur and about 3·1 times as long as broad; chela typical in general appearance, 3·8 times as long as broad; fingers much (1·7 times) longer than hand, and about the same length as the carapace and femur; hand 1·2 times as broad as deep. Length of male 1·7–1·8 mm. A very active and graceful species.

Albiorix edentatus, sp. n. (Figs. 2 Y, AA; fig. 1 C.)

Holotype, ♂ (JC. 266.01003); paratypes, 4 immature females (probably) (JC. 266.01001–2 and 4). Collected singly under large boulders on yellow pine-covered hillside, Santa Isabella Creek, east slope of Mt. Hamilton, California. Coll. by author v.18.1924.

Diagnosis. Chela typical, marginal teeth of fingers much reduced and inconspicuous throughout, but, as usual, somewhat more prominent on the fixed than the movable finger; teeth contiguous, but very broad and strongly retro-cuneate, so that the tooth-caps themselves appear as a widely spaced linear series of minute tubercles along the dental margin of the finger (fig. 2 AA); fixed finger with a total of 30–33 marginal teeth; movable finger with about 27, which are only slightly less developed than those of the fixed finger (fig. 2 Y), unlike the case in *mexicanus* or *parvidentatus*. Carapace normal and about the same length or shorter than the femur. Palp slender and typical in appearance, more or less clearly granulate on all its segments, but less conspicuously so than in *parvidentatus.* Trochanter 2·1–2·3 times as long as broad; femur about as long as or shorter (latter in young specimens) than fingers of chela, about same length as carapace, 4·1 times as long as broad; tibia 3·0–3·2 times as long as broad; chela 3·6 times as long as broad; fingers very much longer than hand, subequal to femur and carapace; hand 1·15–1·20 times as broad as deep. Length of male 2·4 mm.

Remarks. This beautiful and agile form is most nearly related to *parvidentatus,* from which it differs in the dentition of the chela and larger size.

Genus DHANUS, nov.

Orthotype. *Ideoroncus sumatranus,* Redikorzev.

Diagnosis and Remarks. In addition to the characters noted in the key, it may be observed that a small lamina exterior may be present or absent.

The two included species are both south Oriental. They may be separated by means of the following couplet:—

1. Marginal teeth of movable finger weakly developed or obsolete except for the first six or seven; marginal teeth of fixed finger moderately developed throughout; lamina exterior completely absent: small, non-cave-dwelling species, about 2·0 mm. long .... *siamensis* (With), [p. 47.

Marginal teeth of movable finger strongly developed throughout, as well developed as on the fixed finger; small lamina exterior present: large cave-inhabiting species, about 3·5 mm. long .... *sumatranus* [(Redikorzev), p. 47.

Dhanus siamensis (With).

1906. *Ideoroncus siamensis,* With, p. 81, figs.

Remarks. Through the courtesy of Dr. Kai L. Henriksen I have been privileged to examine one of With's original specimens (♂ (JC. 446.01001)), from Klong Salakpet, Siam.

The general form of this species bears a considerable superficial similarity to members of the genus *Albiorix.*

Dhanus sumatranus (Redikorzev). (Fig. 2 FF; fig. 3 C.)

1922. *Ideoroncus sumatranus,* Redikorzev, p. 545, figs.

Material examined. Two ♂ and three ♀ (JC. 103.01001–5), labelled "Batu caves; in the permanently dark places in the caves." Coll. E. Mjöberg.

Redikorzev's type-material came from "Sumatra, Datu Caves, lower cave, dark, 25.i.1913."

As to whether the two foregoing localities are the same I am unable to ascertain. I had presumed that Mjöberg's material was from Borneo. In response to a direct query concerning this point Mjöberg stated that "all specimens are from Northern Sarawak."

Remarks. My material agrees very well with Redikorzev's excellent description. His figure of the chela, however, is erroneous in that it omits the venom-duct of the movable finger.

Genus SHRAVANA, nov.

Orthotype. *Ideoroncus laminatus,* With.

Diagnosis and Remarks. Adequately characterized in key. The longitudinal division of the tergites and sternites is unique in the Neobisioidea. The genotype and only known species is from Siam.

Shravana laminata (With).

1906. *Ideoroncus laminatus,* With, p. 84, figs.

Material examined. Through the kindness of Dr. Kai L. Henriksen I have been privileged to examine one of With's original specimens, ♀ (JC. 445.01001), from Koh Chang, Siam.

[To be continued.]

II.—*On a new Galago from South-east Africa, with a Note on* Otolicnus garnettii, *Ogilby.* By ERNST SCHWARZ.

IN revising the series of Galagos in the British Museum, the following new race has been found to need description. I have much pleasure in naming it after Professor Einar Lönnberg, the distinguished head of the Naturhistoriska Riksmuseum, Stockholm:—

Galago crassicaudatus lönnbergi, subsp. n.*.

Type-locality. Tambarara, Gorongoza Mts., Portuguese East Africa.

Type. ♂, B.M. no. 8. 1. 1. 17. Collected by Major C. H. B. Grant, 23rd April, 1907 (Rudd Coll.).

---

* *Galago crassicaudatus,* Thomas and Wroughton, P. Z. S. 1908, p. 166.

Specimens examined. Thirteen, from the type-locality, from Vumba, Gorongoza Mts., and from Melsetter, Rhodesia.

Closely related to *G. c. crassicaudatus* as defined by Thomas*, but darker and with the tail washed with cinnamon-buff.

Upperside grey washed with buffy brown. Colour of arms always distinctly set off from the body-colour, cinnamon-buff; that of the thighs creamy buff. Finger and toes, not the metacarpus, coffee-brown. Lower surface always slightly washed with buffy. Tail always lighter at the tip, distinctly washed with cinnamon-buff. Face very pale, no distinct nasal stripe, but all the hairs in front of the frontal crest fairly pale and generally contrasted with the colour of the crown.

Dimensions of type:—Head and body 287 mm.; tail 371; hind foot 92; ear 57.

Skull: basal length 55. This is a subadult specimen with the basal suture not entirely ankylosed. In a specimen from Vumba (B.M. no. 20. 9. 1. 1, ♂ old) I have taken the following measurements:—Basal length 61·6 mm., upper length 77·1; zygomatic width 51·4; length of upper tooth-row (C–M^3) 27·7; premolar–molar series (P^2–M^3) 22·2.

This local race of Galago is most nearly related to *crassicaudatus*, but is more tinged with brownish or yellowish both above and below, and especially on the tail, has a pale face without distinct markings, and the fingers and toes dark. It is intermediate between *crassicaudatus* and *umbrosus*, to which the Vumba skins have originally been assigned at the British Museum, but differs clearly from the latter, which has a much darker colour above and a greyish tinge below, dark brown hands and feet, and a dark or blackish tail-tip.

The type-specimen of *Otolicnus garnettii*, Ogilby, which Thomas believed to belong to one of the northern races, is a full-grown specimen which lived at the Zoological Gardens, London, for several years. The very small size of its skull, which induced Thomas to deny its southern origin, is, however, probably due to confinement—in fact, the presence of a parietal plate instead of a sagittal crest, the thickness of the bone, the incomplete ossification of the nasals, are exactly the changes one would expect in an animal with ostitis fibrosa, and which frequently interfere with the process of growth itself.

As regards the skin of the specimen (B.M. no. 55. 12. 24. 50), which is in a good condition, only that the tail-tip is missing, it agrees in every detail except size with a specimen from the Cape (B.M. no. 49. 30. 10) and fairly closely with two specimens (B.M. no. 4. 12. 3. 6–7) from the Ngoye Hills, Zululand. It is a brownish, not a buffy and grey animal, its fur is thick and abundant, and, above all, the supraorbital marks are large, as in all the southern animals like *umbrosus* and *lönnbergi*, and not reduced as in the Kenya (*G. c. lasiotis*, Peters) and Zanzibar (*G. c. agisymbanus*, Coquerel) animals. To conclude, the specific name *garnettii*, Ogilby, will have to stand as the subspecific name for the Cape race of *G. crassicaudatus*, with *zuluensis*, Elliot, as a synonym.

---

* Ann. & Mag. Nat. Hist. (8) xx. p. 49 (1917).

III.—*New Genera and Species of* Phycitinæ (*Lepidoptera*, Pyralidæ). By Sir George F. Hampson, Bart.

[Published by permission of the Trustees of the British Museum.]

Genus Africella, nov.

Type, *A. micræola.*

Palpi upturned, slender, the second joint reaching to about middle of frons, the third moderate; frons smooth; eyes large, round; antennæ of male somewhat laminate and and minutely ciliated. Fore wing narrow; vein 2 from near angle of cell; 3 and 5 separate, 4 absent; 6 from upper angle; 9 absent; 10–11 from cell. Hind wing with vein 2 from just before angle of cell; 3 and 5 on a long stalk, 4 absent; the discocellulars oblique and not angled; 6–7 shortly stalked; 8 anastomosing with 7 to near apex.

Africella micræola, sp. n.

♂. Head, thorax, and abdomen reddish brown mixed with grey-white; antennæ fuscous, ringed with white except towards tips; anal tuft white tinged with ochreous. Fore wing grey-white irrorated with fuscous-brown, the costa and terminal area more suffused with fuscous-brown; the antemedial line represented by a small black-brown spot on vein 1; a dark shade from costa to median nervure; two distinct black discoidal points; subterminal line grey-white, almost straight; cilia with a fine dark line near base. Hind wing semihyaline white tinged with brown, the veins and termen browner; cilia with a brown line near base.

Gold Coast, Bibianaha (*Spurrell*), ♂ type. *Exp.* 10 mm.

Africella amydra, sp. n.

♀. Head, thorax, and abdomen dark reddish brown mixed with grey; the antennæ blackish, the palpi, pectus, legs, and ventral surface of abdomen whitish mixed with red-brown, the tarsi black-brown ringed with white. Fore wing grey-white suffused and irrorated with dark reddish brown; the first line medial, whitish defined on outer side by blackish, oblique, sinuous; two distinct black discoidal points; subterminal line whitish defined on inner side by blackish, sinuous. Hind wing semihyaline whitish tinged with red-brown especially on the veins and towards termen; a blackish terminal line; cilia white tinged with red-brown except at base and tips.

Br. E. Africa, Escarpment (*Doherty*), 1 ♀ type. *Exp.* 16 mm.

Genus Taprobania, nov.

Type, *T. glaucochroa.*

Proboscis fully developed, palpi upturned, smoothly scaled, the second joint reaching to just above vertex of head, the third rather long; maxillary palpi filiform; frons smooth, with ridge of scales above; eyes large, round; antennæ of female often simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; veins 2–3 from near angle of cell, downcurved; 4–5 from angle; 6 from below upper angle; 9 absent; 10–11 from cell. Hind wing with the cell about one-third length of wing; vein 2 from angle; 3 and 5 strongly stalked, 4 absent, the discocellulars oblique, not angled; 6–7 stalked; 8 anastomosing with 7 to about three-fourths of wing.

Taprobania glaucochroa.

†*Homœsoma glaucochroa*, Hmpsn. Journ. Bomb. Nat. Hist. Soc. xviii. p. 260 (1908).

Ceylon.

Genus Rhynchephestia, nov.

Type, *R. rhabdotis.*

Proboscis fully developed; palpi downcurved, extending about twice the length of head and moderately scaled below to end of second joint; maxillary palpi slightly dilated with scales; frons smooth; eyes large, round; antennæ of male laminate and thickened towards base, almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from close to angle of cell;

3 and 5 separate, 4 on a very long stalk with 5 or absent; 6 from upper angle; 9 absent; 10–11 from cell. Hind wing with vein 2 from well before angle of cell; 3 and 5 separate, 4 absent; the discocellulars inwardly oblique, not angled; 6–7 from upper angle of cell; 8 anastomosing with 7 to three-fourths of wing.

Rhynchephestia rhabdotis, sp. n.

♂. Head and thorax black-brown with a leaden gloss, the vertex of head at sides, genæ, and a ring round neck fulvous, the palpi white to towards extremity of second joint where the white ends obliquely, the antennæ black-brown; abdomen black-brown; pectus, legs, and ventral surface of of abdomen white tinged with brown, the legs with some blackish. Fore wing glossy black-brown; the costal area irrorated with white to beyond middle; a rather diffused white fascia from base through the cell to just beyond it with some white irroration below it and beyond it where it extends to just below the costa. Hind wing dark brown; cilia brownish white with a dark line near base. Underside of fore wing with the inner area whitish; hind wing white tinged with brown.

HAWAII, Maui (*Terry*), 2 ♂ type. *Exp.* 20 mm.
Larva on *Argyroxiphium*.

Genus NEONONIA, nov.

Type, *N. taprobalis*.

Proboscis fully developed; palpi upturned to about vertex of head and smoothly scaled, the third joint as long as the second; maxillary palpi filiform; frons smooth; eyes large, rounded; antennæ of male almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell; 3 and 5 shortly stalked, 4 absent; 6 from below upper angle; 9 absent; 10–11 from cell. Hind wing with vein 2 from well before angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars erect and slightly angled, 6–9 shortly stalked; 8 anastomosing with 7 to three-fourths of wing.

Neononia taprobalis.

Nonia taprobalis, Hmpsn. Journ. Bomb. Nat. Hist. Soc. xviii. p. 259 (1907).

CEYLON.

Genus UNADILLIDES, nov.

Type, *U. distichella.*

Proboscis fully developed; palpi obliquely upturned, extending to about the vertex of head and moderately fringed with scales below; maxillary palpi slightly dilated with scales at extremity; frons smooth; eyes large, round; antennæ of male somewhat annulate and almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from towards angle of cell; 3 and 5 separate, 4 absent; 6 from upper angle; 9 absent; 10–11 from cell. Hind wing with vein 2 from near angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars angled; 6–7 stalked; 8 anastomosing with 7 to near apex.

Unadillides distichella.

Homœosoma distichella, Meyr. Pr. Linn. Soc. N.S.W. iii. p. 215 (1878); Rag. Rom. Mém. viii. p. 262, pl. 39. f. 20.

QUEENSLAND; N.S. WALES; VICTORIA.

Unadillides microphæa, sp. n.

Head and thorax dark red-brown mixed with some whitish; abdomen whitish suffused with red-brown; tarsi dark brown ringed with white. Fore wing dark red-brown irrorated with whitish, the terminal area rather darker; a whitish medial line, excurved in submedian interspace; a whitish subterminal line incurved below costa and at submedian fold; cilia with a white line at base. Hind wing ochreous-white tinged with red-brown especially towards termen, the veins red-brown; cilia with an ochreous-white line at base.

SIERRA LEONE (*Clements*), 2 ♂ type. *Exp.* 10–12 mm.

Genus NASUTES, nov.

Type, *N. venata.*

Proboscis fully developed; palpi downcurved, about three times length of head and moderately scaled below; maxillary palpi filiform; frons smooth; eyes large, round; antennæ of male ciliated; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from long before angle of cell; 3 and 5 separate, 4 absent; 6 from upper angle; 9 absent; 10–11 from cell. Hind wing with vein 2 from near angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars strongly angled; 6–7 stalked; 8 anastomosing with 7 to near apex.

Nasutes venata, sp. n.

♂. Head and thorax whitish tinged with brownish ochreous, the shoulders and outer part of patagia fuscous, pencilled with white, the antennæ blackish below, the palpi fuscous pencilled with white; abdomen white suffused with fuscous leaving white segmental lines, the anal tuft ochreous-white; pectus, legs, and ventral surface of abdomen white mixed with fuscous. Fore wing brownish ochreous, the costal area white irrorated with black, the veins white defined by black formed by streaks of black scales; cilia white mixed with fuscous. Hind wing white strongly tinged with fuscous-brown, the cilia whiter.

U.S.A., Colorado, Boulder (*Cockerell*), 1 ♂ type. *Exp.* 20 mm.

Genus CHRYSOSCINIA, nov.

Type, *C. plicata.*

Proboscis fully developed; palpi upturned, the second joint reaching to about vertex of head and moderately scaled, the third nearly as long as the second and with triangular tuft of scales in front; frons smooth, with tuft of scales above; eyes large, round; antennæ of male somewhat laminate and almost simple; the vertex of head tufted with scales; tibiæ smoothly scaled; abdomen of male long and with lateral tufts of scales on medial segments. Fore wing narrow, the costa moderately arched, the apex rounded, the termen evenly curved; vein 2 from long before angle of cell, curved; 3 from well before angle; 4–5 from angle, in line with the median nervure; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about one-third length of wing; vein 2 from just before angle of cell; 3 and 5 stalked, 4 absent; the discocellulars angled; 6–7 shortly stalked; 8 anastomosing with 7; the male with a strong fold thickened by a ridge of scales just below the cell extending to about three-fourths of wing.

Chrysoscinia plicata, sp. n.

Head and thorax pale rufous, the frons and ridge of scales above it black in male, the antennæ fuscous, the palpi with the third joint black; abdomen golden orange, the basal segment pale rufous; pectus and legs pale reddish brown, the tibiæ and tarsi banded with fuscous. Fore wing flesh-colour suffused with dark purple-brown; short oblique blackish streaks from base of costa and median nervure; antemedial line almost medial, rather diffused blackish with some silvery-white scales on its outer edge, strongly angled outwards below costa at median nervure and above inner margin; subterminal line white defined on inner side by blackish brown, slightly excurved at middle; an orange line at base of cilia. Hind wing orange, strongly suffused with brown except on inner area and cilia.

BR. N. GUINEA, Milne Bay (*Meek*), 1 ♂, 1 ♀ type. *Exp.* 16 mm.

C ✓ Genus MESCINIELLA, nov.

Type, *M. micans.*

Proboscis fully developed; palpi upturned, the second joint reaching to vertex of head, in male rather broadly scaled in front, in female moderately scaled, the third in male short and thickly scaled, in female as long as the second joint and smoothly scaled; maxillary palpi filiform; frons rather hollowed out in centre in male, smooth in female; eyes large, round; antennæ of male somewhat laminate and almost simple; fore and mid tibiæ smoothly scaled, the hind tibiæ with tuft of hair above at extremity. Fore wing narrow, the costa rather strongly arched towards apex which is rounded, the termen evenly curved; veins 2 and 3 stalked from well before angle of cell, curved; 4–5 from angle; 6 from upper angle; 8 and 10 stalked, 9 absent; 11 from cell. Hind wing with the cell about one-third length of wing; vein 2 from well before angle of cell; 3 and 5 stalked, 4 absent; the discocellulars curved; 6–7 shortly stalked; 8 anastomosing with 7 to near apex; the male with a large lobe at base of costa, its extremity tufted with hair, a fringe of hair beyond it for a short distance just below the costa.

Mesciniella micans.

Euzophera micans, Hmpsn. Moths Ind. iv. p. 74 (1896); id. Rom. Mém. viii. p. 86, pl. 48. f. 3.

CEYLON.

C ✓ Genus CAUSTELLA, nov.

Type, *C. micralis.*

Proboscis fully developed; palpi upturned, the second joint reaching to about middle of frons and moderately scaled in front, the third moderate and thickly scaled except at tips; maxillary palpi filiform; frons smooth, without tuft of scales; eyes large, round; antennæ of male minutely ciliated; mid and hind tibiæ moderately fringed with hair. Fore wing rather narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, 3 from angle; 4–5 shortly stalked; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 and 5 on a long stalk, 4 absent; the discocellulars straight and erect; 6–7 from upper angle; 8 anastomosing with 7 to near apex.

Caustella micralis.

Heterographis micralis, Hmpsn. Moths Ind. iv. p. 70 (1896); id. Rom. Mém. viii. p. 28, pl. 48. f. 19.

TRANSVAAL; NATAL, Durban in coll. Janse; CEYLON.

Caustella phœnicias, sp. n.

Head and thorax black glossed with leaden grey usually with more or less purplish red near extremity of the patagia; abdomen grey tinged with fuscous and with some ochreous at extremity; pectus and legs grey suffused with black, the tarsi ringed with white. Fore wing with the basal half purple-red, the costa suffused with black and irrorated with silvery-grey scales; an ill-defined ochreous band tinged with red just beyond middle, narrowing to costa; the rest of wing black irrorated with silvery-grey and with a narrow purple-red subterminal band not reaching the costa. Hind wing grey tinged with fuscous; a dark terminal line and whitish line at base of cilia.

TRANSVAAL, Pretoria (*Janse*), 1 ♂, 3 ♀ type. *Exp.* 12–14 mm.

Caustella strigifera, sp. n.

Euzophera cinerosella, Hmpsn. Mon. Christmas I. p. 73 (nec Zell).

Head, thorax, and abdomen white mixed with red-brown. Fore wing white suffused with red-brown and slightly irrorated with blackish, the costal area whiter to near apex where it tapers to a point; a black streak below basal part of costa and slight streak below the cell near base; a medial black point on median nervure; an obscure white discoidal bar defined by black scales and with black streaks just before and beyond it on the veins to near termen, interrupted except towards costa by the indistinct whitish subterminal line which is oblique below vein 4; a terminal series of black points. Hind wing whitish suffused with red-brown, the cilia whiter.

CHRISTMAS I. (*Andrewes*), 1 ♂, 1 ♀ type. *Exp.* 18 mm.

Genus MASCELIA, nov.

Type, *M. ectophæa*.

Proboscis fully developed; palpi upturned, the second joint reaching to about middle of frons and rather broadly scaled in front, the third long and thickly scaled to near tip; maxillary palpi dilated with scales; frons smooth; eyes large, round; antennæ of male strongly laminate and almost simple; fore and mid tibiæ smoothly scaled, the hind tibiæ with tuft of hair above at extremity; abdomen with lateral tufts of scales. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell, curved; 3 from just before angle; 4–5 from angle, not in line with the median nervure; 6 from angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 and 5 from angle, 4 absent; the discocellulars curved; 6–7 shortly stalked; 8 anastomosing with 7.

Mascelia ectophæa.

Euzophera ectophæa, Hmpsn. Journ. Bomb. Nat. Hist. Soc. xviii. p. 262, pl. E. f. 19 (1908).

CEYLON.

Genus PHESTINIA, nov.

Type, *P. costella*.

Proboscis fully developed; palpi upturned, moderately scaled, the second joint reaching to about vertex of head, the third long; maxillary palpi dilated with scales and flattened against the frons which is smooth and with a tuft of hair above; eyes large, round; antennæ of male with slight tufts of scales at the joints; tibiæ slightly fringed with hair. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from just before angle of cell, oblique; 3 and 5 stalked, 4 absent; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about one-third length of wing; vein 2 from middle of cell; 3 and 5 from angle, 4 absent; the discocellulars oblique; 6–7 stalked; 8 anastomosing with 7 almost to apex.

Phestinia costella, sp. n.

♂. Head red-brown; thorax and abdomen red-brown mixed with white; pectus, legs, and ventral surface of abdomen white mixed with some red-brown, the tarsi red-brown ringed with white. Fore wing whitish suffused with red-brown, the costal area nearly pure white with the costal edge brown towards base, the terminal area slightly suffused with red-brown and with dark streaks below veins 6, 5, 3; the first line almost medial, oblique to median nervure where it is angled outwards, then inwardly oblique; two blackish discoidal points; subterminal line indistinct, whitish defined on inner side by brown, oblique; a slight dark terminal line. Hind wing white suffused with reddish brown, the cilia nearly pure white.

JAMAICA, Constant Springs (*Walsingham*), 1 ♂ type. *Exp.* 20 mm.

Genus SYMPHESTIA, nov.

Type, *S. ephestialis.*

Proboscis fully developed; palpi upturned, moderately scaled, the second joint reaching to about middle of frons, the third moderate; maxillary palpi minute and slightly dilated with scales; frons smooth; eyes large, round; antennæ of female somewhat laminate and almost simple; tibiæ smoothly scaled. Fore wing rather narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 and 5 from angle, 4 absent; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 and 5 stalked, 4 absent; the discocellulars oblique; 6–7 shortly stalked; 8 strongly anastomosing with 7.

Symphestia ephestialis.

Euzopherodes ephestialis, Hmpsn. Journ. Bomb. Nat. Hist. Soc. xv. p. 24 (1903).

SIKHIM.

Genus JACUTSCIA, nov.

Type, *J. strigata.*

Proboscis fully developed; palpi downcurved, extending about twice the length of the head and thickly scaled; maxillary palpi of male brush-like in a fold of the labial palpi; frons with slight conical prominence with raised edges; eyes large, round; antennæ of male with the basal joint long, the shaft laminate and almost simple, with a sinus at base containing slight scale-like teeth; tibiæ smoothly scaled. Fore wing rather narrow, the costa evenly arched, the apex rounded, the termen obliquely curved; vein 2 from towards angle of cell, curved; 3 from angle; 4 absent; 5 not in line with the median nervure; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing; vein 2 from angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars obliquely curved; 6–7 stalked; 8 anastomosing with 7.

Jacutscia strigata, sp. n.

♂. Head, thorax, and abdomen ochreous-white mixed with some pale red-brown; pectus, legs, and ventral surface of abdomen ochreous-white irrorated with brown. Fore wing ochreous-white with diffused streaks of dark brown irroration along the veins. Hind wing grey-brown, the cilia whitish with a brown line near base. Underside grey-brown.

N. SIBERIA, Schigansk, 1 ♂ type. *Exp.* 30 mm.

Genus ETHIOPSELLA, nov.

Type, *E. nasuta.*

Proboscis fully developed; palpi downcurved, extending about three times length of head, the second joint thickly scaled above; maxillary palpi slightly dilated with scales; frons smooth; eyes large, round; antennæ of female almost simple, the basal joint rather long; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from well before angle of cell, oblique; 3 and 5 from angle, 4 absent; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing; vein 2 from just before angle of cell; 3 and 5 on a long stalk, 4 absent; the discocellulars curved; 6–7 from upper angle; 8 anastomosing with 7 to about three-fourths of wing.

Ethiopsella nasuta, sp. n.

♀. Head and thorax grey-brown mixed with some pale reddish; abdomen grey-brown; pectus, legs, and ventral surface of abdomen dark brown mixed with whitish, the tarsi black-brown ringed with white. Fore wing grey-brown mixed with some pale reddish and with obscure dark streaks on the veins; an indistinct dark antemedial line from cell to inner margin, small discoidal spot, and oblique postmedial line slightly incurved at submedian fold. Hind wing semihyaline white, the costa slightly tinged with brown; a fine brown terminal line and line near base of cilia.

S. NIGERIA, Baro (*Simpson*), 1 ♀ type. *Exp.* 20 mm.

Genus OGILVIA, nov.

Type, *O. pulverealis*.

Proboscis fully developed; palpi downcurved, extending about three times length of head and thickly scaled; maxillary palpi dilated with scales and appressed to the frons which is rounded and with a tuft of scales; eyes large, round; antennæ of male somewhat laminate and almost simple; fore and mid tibiæ smoothly scaled, the hind tibiæ with slight tufts of hair above at base and extremity. Fore wing rather narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 from just before angle; 4–5 from angle, not in line with the median nervure and approximated for some distance; 6 from upper angle, 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from near angle of cell which is produced; 3 and 5 from angle and approximated for some distance, 4 absent; the discocellulars curved; 6–7 from upper angle; 8 not anastomosing with 7.

Ogilvia pulverealis.

Hypogryphia pulverealis, Hmpsn. Bull. Liverp. Mus. ii. p. 39 (1899); id. Nat. Hist. Sokotra, p. 333, pl. xx. f. 16.

SOKOTRA.

Genus ŒDOTHMIA, nov.

Type, *Œ. endopyrella*.

Proboscis fully developed; palpi upturned, the second joint reaching to well above vertex of head and moderately scaled, the third moderate and thickly scaled; maxillary palpi triangularly scaled and flattened against the frons, which has a thickly scaled pointed conical prominence; eyes large, round; antennæ of male somewhat laminated and almost simple, the basal joint rather large, the shaft very slightly excised at base; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from just before angle of cell, curved and closely approximated to 3; 3 and 5 from angle, 4 absent; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing, its lower extremity produced; vein 2 from just before angle of cell; 3 and 5 strongly stalked; the discocellulars very oblique; 6–7 shortly stalked; 8 anastomosing with 7 to about three-fourths of wing.

Œdothmia endopyrella, sp. n.

Eurythmia ignidorsella, Druce, Biol. Centr.-Am., Het. ii. p. 565 (part.), nec Rag.

♂. Head, tegulæ, and patagia whitish tinged with pale red, the outer edge of patagia and dorsum of thorax black, the antennæ blackish above, the palpi pale red, whitish in front, the third joint blackish; abdomen brownish white with some black at base; pectus and legs pale red mixed with some white. Fore wing black-brown; a white costal fascia irrorated with pale red, narrowing to a point at apex: a few silvery scales above medial part of vein 1 and near end of cell; two pale fulvous-red spots on inner medial area, conjoined below vein 1. Hind wing white with some brown suffusion on terminal area except towards tornus and a dark terminal line; cilia white with a brownish line near base.

Mexico, Vera Cruz, Atoyac (*Schumann*), 1 ♂ type Godman-Salvin Coll. *Exp.* 18 mm.

Genus Synothmia, nov.

Type, *S. bahamasella.*

Proboscis fully developed; palpi upturned, the second joint reaching to well above vertex of head and moderately scaled, the third moderate and thickly scaled; maxillary palpi of female filiform; frons smooth; eyes large, round; antennæ of female almost simple, the basal joint rather long, the shaft very slightly excised at base; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from close to angle of cell, curved; 3 and 5 from angle, 4 absent; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing, its lower extremity strongly produced; vein 2 from just before angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars strongly angled; 6–7 from upper angle; 8 anastomosing with 7 to about three-fourths of wing.

Synothmia bahamasella, sp. n.

♀. Head and thorax dark reddish brown mixed with some grey-white, the antennæ blackish, the palpi whitish to middle of second joint, then blackish; abdomen reddish brown, obscurely banded with grey-white, the anal tuft ochreous; pectus, legs, and ventral surface of the abdomen dark brown mixed with grey-white. Fore wing black-brown with a few silvery-white scales, the costal area white irrorated with pale red, extending in end of cell to discal fold, then narrowing to apex, a small red spot on it at upper angle of cell; some pale red on basal inner area and a patch on medial area from submedian fold to inner margin, its outer edge oblique, the antemedial line represented by the dark area between these two patches and a small white spot on vein 1; a minute white spot at lower angle of cell; an oblique silvery-white subterminal line. Hind wing white tinged with brown especially on terminal area; a dark terminal line; cilia whitish with a brown line through them.

BAHAMAS, Nassau (*Sir G. Carter*), 1 ♀ type. *Exp.* 16 mm.

Genus CAYENNIA, nov.

Type, *C. rufitinctalis.*

Proboscis fully developed; palpi upturned, the second joint reaching to about middle of frons and slenderly scaled in front, the third moderate; maxillary palpi filiform; frons smooth; eyes large, round; antennæ of male somewhat laminate and minutely ciliated; tibiæ slightly fringed with hair. Fore wing rather narrow, the costa arched towards apex which is rounded, the termen obliquely curved; vein 2 from towards angle of cell, curved; 3 from before angle; 4–5 stalked, not in line with the median nervure; 6 from below upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing; vein 2 from just before angle of cell; 3 and 5 strongly stalked, 4 absent; 6–7 stalked; 8 anastomosing with 7 to near apex.

Cayennia rufitinctalis, sp. n.

♂. Head and thorax grey mixed with brown; abdomen grey suffused with fuscous-brown. Fore wing grey, irrorated with fuscous, the basal half of inner area and the tornal half of terminal area tinged with rufous; medial line whitish defined on each side slightly by rufous and with minute black streaks before and beyond it on the veins; black points at angles of cell and others on bases of veins 2–3; postmedial line very indistinct; pale, defined by black marks before and beyond it on costa and minute black streaks before it on the veins; a terminal series of black points. Hind wing semihyaline whitish tinged with brown, especially on the veins and terminal area.

FR. GUIANA, Cayenne (*Schaus*), 1 ♂ type. *Exp.* 18 mm.

Genus Penetiana, nov.

Type, *P. proleucia.*

Proboscis fully developed; palpi upturned to just above vertex of head, smoothly scaled, the third joint moderate; maxillary palpi filiform; frons smooth; eyes large, round; antennæ of male somewhat laminate and almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from well before end of cell, oblique; 3 and 5 from angle, 4 absent; 6 from upper angle; 8–9 stalked; 10–11 from cell, 10 closely approximated to 8–9. Hind wing with the cell about half the length of wing, its lower angle produced; vein 2 from angle; 3 and 5 strongly stalked, 4 absent; the discocellulars angled; 6–7 stalked; 8 anastomosing with 7 to towards apex.

Sect. I.—Antennæ of male with the shaft excised towards base and with slight scale-teeth in the excision.

Penetiana penthetria, sp. n.

♂. Head, thorax, and abdomen black with a leaden gloss; tarsi ringed with white; ventral surface of abdomen black irrorated with white, the sides and terminal segments white tinged with brown. Fore wing black-brown glossed with leaden grey; antemedial line silvery grey, oblique; a slight white discoidal bar; subterminal line silvery grey, slightly incurved below costa. Hind wing semihyaline white, the costal area suffused with fuscous; a fine black terminal line except towards tornus. Underside of fore wing whitish suffused with fuscous except on inner area.

Port. E. Africa, M. Chiperone (*Neave*), 1 ♂ type. *Exp.* 26 mm.

Sect. II.—Antennæ of male without sinus at base of shaft.

Penetiana proleucia, sp. n.

Head and thorax pale brown mixed with whitish; abdomen white tinged with ochreous-brown, the ventral surface brown. Fore wing whitish suffused and irrorated with brown, the costal area white except towards base, ill-defined below; subterminal line indistinct, whitish defined on inner side by brown, somewhat angled outwards below costa, then oblique; a dark terminal line and fine white line at base of cilia. Hind wing white slightly tinged with brown; a fine brown terminal line.

S.E. Borneo (*Doherty*), 1 ♂ type; Philippines, Luzon, Mt. Makiling (*Baker*), 1 ♀. *Exp.* 16 mm.

Genus AUCHMERA, nov.

Type, *A. falsalis.*

Proboscis fully developed; palpi obliquely upturned, moderately scaled, the second joint reaching to about vertex of head, the third short; maxillary palpi filiform; frons smooth; eyes large, round; antennæ of male with the basal joint long and thickly scaled, the shaft with sinus at base, strongly ciliated; tibiæ smoothly scaled, the mid-tibiæ of male dilated with a fold containing a tuft of hair. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from near angle of cell, curved; 3 from angle; 4–5 strongly stalked in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars obliquely curved; 6–7 stalked; 8 not anastomosing with 7.

Auchmera falsalis.

Heterographis falsalis, Hmpsn. Journ. Bomb. Nat. Hist. Soc. xviii. p. 261 (1908).

MADRAS, Gooty.

Auchmera yezonis, sp. n.

♂. Head, thorax, and abdomen pale red-brown; pectus and legs red-brown mixed with some white. Fore wing greyish suffused with red-brown; antemedial line indistinct, sinuous, pale with tufts of raised blackish scales on its outer side in and below the cell; slight dark medial marks on median nervure and at inner margin; an indistinct oblique diffused brown postmedial line. Hind wing white suffused with red-brown; a dark terminal line and fine white line at base of cilia.

JAPAN, Yezo, Hakodaté (*Andrews*), 1 ♂ type. *Exp.* 24 mm.

Auchmera melanodes, sp. n.

♀. Head and thorax black-brown suffused with grey-white; abdomen fuscous with brownish-white segmental bands; pectus and ventral surface of abdomen brownish white; legs black-brown irrorated with white, the tarsi ringed with white. Fore wing black-brown irrorated with grey-white; a grey-white antemedial band traversed by a black line which is rather oblique to median nervure; a faint blackish discoidal spot; subterminal line indistinct, grey-white, excurved at middle. Hind wing whitish suffused with brown, especially on the veins, costal and terminal area; a dark terminal line; cilia white with a dark line near base.

W. AUSTRALIA, Waroona (*Berthoud*), 1 ♀ type. *Exp.* 18 mm.

Auchmera homographis, sp. n.

♀. Head, thorax, and abdomen whitish tinged with reddish brown, the antennæ fuscous ringed with whitish; pectus and legs white mixed with some brown, the tarsi ringed with brown; ventral surface of abdomen ochreous-white. Fore wing grey-white mixed with pale reddish brown and some blackish; antemedial line whitish with slight blackish points on its outer side at the veins and a patch of blackish irroration before it at inner margin, oblique, sinuous; subterminal line whitish defined on inner side by blackish, very slightly excurved at middle; some blackish scales on termen and a brown line through the cilia; hind wing semihyaline white tinged with brown; a dark terminal line, cilia white.

ALGERIA, Batna (*Eaton*), 1 ♀ type. *Exp.* 20 mm.

Genus TRICHORACHIA, nov.

Type, *T. leonina*.

Proboscis fully developed; palpi upturned, the second joint reaching to vertex of head and rather broadly scaled in front, the third rather long and thickly scaled; maxillary palpi slightly dilated with scales; frons smooth; eyes large, round; antennæ of male somewhat laminate and minutely ciliated; tibiæ slightly fringed with hair. Fore wing rather narrow, the costa slightly arched, the apex rounded, the termen obliquely curved; vein 2 from well before angle of cell, oblique; 3 from before angle; 4–5 stalked, not in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell; the male on underside with oblique ridge of long upturned hair from origin of vein 8 to vein 6 before termen. Hind wing with the cell about one-third length of wing; vein 2 from just before angle of cell; 3 and 5 strongly stalked, 4 absent; 6–7 stalked; 8 not anastomosing with 7.

Trichorachia leonina, sp. n.

♂. Head and thorax red-brown mixed with some whitish; abdomen whitish suffused with rufous. Fore wing red-brown irrorated with whitish; an obliquely curved whitish antemedial line; an oblique whitish subterminial line; a dark terminal line and white line at base of cilia. Hind wing semihyaline white, the costal and terminal areas slightly tinged with ochreous.

SIERRA LEONE (*Clements*), 4 ♂; S. RHODESIA, Umvuma (*Janse*), 1 ♂.

Genus HARRARIA, nov.

Type, *H. rufipicta*.

Proboscis fully developed; palpi with the second joint obliquely porrect, extending about twice the length of head, the third short, downturned; maxillary palpi of male brush-like, in a fold of the labial palpi; frons with horizontally flattened corneous plate covered by a tuft of hair; eyes large, round; antennæ of male minutely ciliated with a slight sinus at base of shaft containing minute scale-teeth; tibiæ smoothly scaled; abdomen with slight crests on two basal segments. Fore wing narrow, the apex rounded, the termen obliquely curved; vein 2 from towards angle of cell, curved; 3 from just before angle; 4–5 from angle, in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from angle of cell; 3 and 5 strongly stalked, 4 absent; the discocellulars obliquely curved; 6–7 stalked; 8 not anastomosing with 7.

Harraria rufipicta, sp. n.

♂. Head and thorax greyish suffused with rufous, the antennæ brown, greyish above, the palpi brownish grey, the third joint darker brown; abdomen greyish tinged with fulvous; pectus, legs, and ventral surface of abdomen brownish white. Fore wings brownish grey, the submedian interspace suffused with rufous to the antemedial line which is whitish, oblique, and slightly sinuous, a patch of rufous and black scales on its inner side at inner margin, and blackish points on its outer side below costa and at median nervure and vein 1; a small rufous discoidal spot with some blackish scales on it, crossed by a rufous streak from before end of cell to the subterminal line, which is whitish defined on inner side by black-brown, oblique towards costa and slightly angled inwards at discal and submedian folds; the terminal area suffused with rufous and with some black-brown scales towards termen; cilia tinged with rufous.

Hind wing semihyaline whitish tinged with rufous ; a brown terminal line; cilia whitish with a brown line near base.

Abyssinia, Harrar (*Degen*), 1 ♂ type. *Exp.* 22 mm.

Genus Homœograpta, nov.

Type, *H. spectrifasciella.*

Proboscis fully developed; palpi of male upturned, with the second joint reaching to rather above vertex of head, moderately scaled in front and hollowed out to receive the brush-like maxillary palpi, the third short and thickly scaled; frons with large thickly scaled conical prominence; eyes large, round; antennæ of male almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen obliquely curved ; veins 2 and 3 curved, from close to angle of cell ; 4–5 from angle ; 6 from upper angle ; 8–9 stalked ; 10–11 from cell. Hind wing with the cell about half the length of wing ; vein 2 from angle of cell ; 3 and 5 on a long stalk, 4 absent; the discocellulars obliquely curved ; 6–7 shortly stalked ; 8 closely approximated to 7 to about three-fourths length of wing.

Homœograpta spectrifasciella.

Staudingeria spectrifasciella, Rag. Ann. Soc. Ent. Fr. 1887, p. 250; id. Rom. Mém. viii. p. 140, pl. 28. f. 14 ; Staud. Cat. Lep. pal. ii. p. 21.

W. Turkestan.

C –

Genus Œdilepia, nov.

Type, *Œ. striginervella.*

Proboscis fully developed; palpi upturned, the second joint reaching to about vertex of head, moderately scaled, in male typically hollowed out to receive the large brush-like maxillary palpi, the third short, thickly scaled; frons smooth, with large tuft of scales above ; eyes large, round ; antennæ of male typically with short branches on outer side towards base, then serrate to about two-thirds length, ciliated on inner side, a small scale-tooth on shaft above towards base, the basal joint long ; the metathorax with paired tufts of scales at sides ; hind tibiæ with slight tufts of hair above at base and extremity ; abdomen with minute flattened dorsal crest at base. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell, curved ; 3 from just before angle ; 4–5 closely approximated for some distance, not in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell; the upper side with oblique antemedial and erect medial series of bosses of raised scales except towards costa. Hind wing with the cell about half the length of wing; its lower extremity produced; vein 2 from before angle of cell; 3 approximated for some distance to 4–5 which are strongly stalked; the discocellulars obliquely curved; 6–7 shortly stalked; 8 not anastomosing with 7.

Sect. I.—Palpi of male with the second joint hollowed out to receive the brush-like maxillary palpi; antennæ with short branches on outer side towards base, then serrate to two-thirds length, ciliated on inner side, a small scale-tooth on shaft above towards base.

Œdilepia striginervella.

Nephopteryx striginervella, Hmpsn. J. Bomb. Nat. Hist. Soc. xv. p. 23 (1903).

CEYLON.

Sect. II.—Maxillary palpi of male filiform, the palpi with large tuft of scales on second joint at extremity behind; antennæ somewhat laminate and almost simple, a sinus at base of shaft containing a double ridge of scales; hind wing on underside with slight streaks of androconia on subcostal and median nervures to end of cell.

Œdilepia stictoglaucella, sp. n.

♀. Head and thorax white slightly mixed with brown, the palpi with the second and third joints blackish at base; abdomen white with brownish bands; tarsi black-brown ringed with white. Fore wing white irrorated with dark brown, obliquely-placed antemedial bosses of raised blackish scales in lower part of cell and above and below vein 1; a white medial line, strongly excurved below costa, then oblique, bosses of raised black scales before it in lower part of cell and above vein 1; a blackish discoidal bar with grey striga in centre, a boss of raised white and dark scales before it, and another in submedian interspace; subterminal line white, interrupted and with short black streaks before and beyond it, strongly bent inwards below costa and with longer streaks before and beyond it, then oblique to vein 5, then dentate, strongly bent inwards in submedian interspace and acutely angled outwards above inner margin, a black mark beyond it on costa; a terminal series of small black spots; cilia white tinged with brown. Hind wing semi-hyaline white, the veins, costal area, and termen tinged with brown; a dark terminal line and brown line near base of cilia.

NATAL, Umkomaas, in Coll. Janse; CAPE COLONY, Annshaw (*Miss F. Barrett*), 3 ♀ type. *Exp.* 24–26 mm.

Genus ASEMEIA, nov.

Type, *A. aprepia.*

Proboscis fully developed; palpi with the second joint obliquely upturned to about vertex of head, rather curved forward at extremity and moderately scaled, the third porrect, short and thickly scaled; maxillary palpi filiform; frons smooth; eyes large, round; antennæ of female somewhat laminate and almost simple; tibiæ smoothly scaled. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell, curved; 3 from just before angle; 4–5 from a point, in line with the median nervure; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hing wing with the cell about one-third length of wing; vein 2 from angle of cell; 3 strongly stalked with 4–5; the discocellulars oblique; 6–7 strongly stalked; 8 anastomosing with 7.

Asemeia aprepia, sp. n.

♀. Head and thorax pale ochreous-brown; abdomen fulvous-yellow, the basal segment pale ochreous-brown; pectus and legs white mixed with pale ochreous-brown. Fore wing pale ochreous-brown mixed with whitish and without markings, except a slightly darker discoidal striga. Hind wing whitish suffused with pale ochreous-brown.

CEYLON, Puttalam (*Pole*), 1 ♀ type. *Exp.* 16 mm.

Genus HOMODIGMA, nov.

Type, *H. geera.*

Proboscis fully developed; palpi upturned, smoothly scaled, the second joint reaching to vertex of head, the third moderate; maxillary palpi triangularly dilated with scales; frons smooth, with a tuft of scales; eyes large, round; antennæ of female somewhat laminate and almost simple; hind tibiæ with a tuft of long hair above from base and fringe of hair towards extremity. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 from just before angle; 4–5 from a point, not in line with the median nervure;

6 from upper angle ; 10 strongly stalked with 8–9 ; 11 from cell. Hind wing with the cell about one-third length of wing ; vein 2 from angle of cell ; 3 strongly stalked with 4–5 ; the discocellulars oblique ; 6–7 stalked ; 8 not anastomosing with 7.

Homodigma geera, sp. n.

♀. Head and thorax red-brown, the frons and palpi whitish suffused with red-brown, the latter with faint red-brown rings near extremity of second joint and at middle of third ; abdomen whitish suffused with red-brown ; pectus and legs grey mixed with red-brown, the hind tibiæ with a black band towards extremity. Fore wing red-brown mixed with grey ; medial line represented by an oblique blackish striga from costa, points on subcostal and median nervures, and a whitish mark in submedian interspace ; subterminal line whitish defined on inner side by dark scales, bent outwards below discal fold, then oblique ; a black terminal line except towards apex and tornus, and ochreous line at base of cilia. Hind wing semihyaline whitish tinged with red-brown ; a darker terminal line and white line at base of cilia, followed by a brown line.

CEYLON (*Alston*) 1 ♀, Peradeniya 1 ♀ type. *Exp.* 20–24 mm.

Genus PROCUNEA, nov.

Type, *P. siderea.*

Proboscis fully developed ; palpi upturned, the second joint reaching to vertex of head, the first and second joints very broadly scaled in front, the third short and thickly scaled ; maxillary palpi long and broadly dilated with scales, porrect and lying between the labial palpi ; frons with very large tuft of scales above, flattened below and rounded above ; eyes large, round ; antennæ of male somewhat laminate and almost simple, a large double ridge of scales at base of shaft but no sinus, the basal joint dilated ; the vertex of head hollowed out and with a large fan of scales behind ; a tuft of hair below base of fore wing, fore femora with large tuft of hair above, the hind tibiæ with tufts of hair above at base and extremity ; abdomen with flattened crests on two basal segments, the second segment rather hollowed out subdorsally. Fore wing narrow, the costa arched, the apex rounded, the termen evenly curved ; the cell narrow and the median nervure slightly curved upwards ; vein 2 from near angle of cell, curved ; 3 from angle ; 4–5 almost from a point ; 6 from upper angle ; 8–9 stalked ; 10–11 from cell.

Hind wing with the cell about one-third length of wing; vein 2 from angle of cell; 3 strongly stalked with 4–5; the discocellulars obliquely curved; 6–7 stalked; 8 not anastomosing with 7; the male with the costa strongly arched, with an elongate patch of rough scales below its basal half on upper side, and vein 8 rather sinuous and not approximated to the cell, and vein 7 from near base to about three-fourths of wing.

Procunea siderea, sp. n.

♂. Head, thorax, and abdomen grey tinged with iron-brown; pectus, legs, and ventral surface of abdomen whitish slightly tinged with brown. Fore wing grey, the costal half irrorated with dark brown, the inner half suffused with iron-brown; a medial black point on vein 1; an obliquely curved postmedial series of short black streaks on veins 6 to 1; a terminal series of black points in the interspaces between veins 8 and 2, with a few black scales beyond them on the cilia. Hind wing semihyaline white, the inner one tinged with ochreous; a fine brown terminal line and line near base of cilia.

QUEENSLAND, Townsville (*Dodd*), 1 ♂ type. *Exp.* 28 mm.

Genus PSAMMIA, nov.

Type, *P. flavipicta*.

Proboscis rather small and slender; palpi downcurved, extending about two and a half times length of head and moderately scaled; maxillary palpi filiform; frons with large rounded prominence with corneous plate below it; eyes large, round; antennæ of male with long cilia; tibiæ smoothly scaled. Fore wing long and narrow, the apex rounded, the termen evenly curved; vein 3 from towards angle of cell, curved; 3 from before angle; 4–5 from a point, not in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about one-third length of wing; vein 2 from angle of cell; 3 strongly stalked with 4–5; the discocellulars angled; 6–7 shortly stalked; 8 not anastomosing with 7.

Psammia flavipicta, sp. n.

♂. Head and thorax ochreous-white with a few brown scales, the antennæ brownish, the frons with black points at sides; abdomen, pectus, and legs ochreous-white, the tarsi ringed with brown. Fore wing ochreous-white irrorated with black; antemedial line black defined on inner side by white and with a fulvous-yellow band before it below discal fold, oblique, waved, a diffused fulvous-yellow fascia beyond it in submedian interspace, and a small discoidal annulus; postmedial line formed by diffused black scales with an ill-defined white band on its outer side, very oblique from costa towards apex to lower angle of cell, then strongly angled outwards and again oblique to inner margin; a diffused black terminal line. Hind wing creamy white with a slight blackish terminal line except towards tornus.

U.S.A., Florida, 1 ♂ type. *Exp.* 24 mm.

Genus MELANASTIA, nov.

Type, *M. bicolor*.

Proboscis rather slender; palpi downcurved, in male extending about twice the length of head, the second joint hollowed out to receive the brush-like maxillary palpi and with tuft of scales above at extremity, the third moderate and thickly scaled, in female extending about three times length of head and smoothly scaled; frons smooth; eyes large, round; antennæ of male with the basal joint long and somewhat dilated, the shaft minutely serrate with a large sinus at base containing a double ridge of scales; tibiæ smoothly scaled. Fore wing narrow, the costa arched, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 from near angle; 4–5 approximated for some distance, not in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 approximated for a short distance to 4–5 which are strongly stalked; the discocellulars curved; 6–7 strongly stalked; 8 not anastomosing with 7.

Melanastia bicolor, sp. n.

Head, thorax, and abdomen glossy black-brown; tarsi ringed with white. Fore wing uniform glossy black-brown irrorated with a few white scales especially on inner area. Hind wing semihyaline white faintly tinged with brown; a brown terminal line and line near base of cilia.

S. NIGERIA, Yorubaland, Ogbomosa (*Sir G. Carter*), 1 ♂, 1 ♀ type; MASHONALAND, Salisbury (*Marshall*), 1 ♂. *Exp.* 20–24 mm.

Genus VELDTICOLA, nov.

Type, *V. striatella.*

Proboscis fully developed; palpi thickly scaled, the second joint upturned to about vertex of head and with slight tuft of scales behind at extremity, the third moderate, porrect; maxillary palpi somewhat dilated with scales; frons smooth; eyes large, round; antennæ of male somewhat laminate and almost simple, the basal joint long, the shaft with a sinus at base containing a double ridge of scales; hind tibiæ with slight tufts of hair above at base and extremity; abdomen with small flattened dorsal crests on the two basal segments. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 from near angle; 4–5 from angle, approximated for some distance and almost in line with the median nervure; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 from angle, approximated for some distance to 4–5 which are strongly stalked; the discocellulars curved; 6–7 shortly stalked; 8 anastomosing with 7. The male on underside with some black androconia on costal area of both wings to beyond middle.

Veldticola persinuella, sp. n.

♀. Head and thorax grey-white tinged with brown, the palpi whitish with an oblique brown band towards extremity of second joint; abdomen dark brown suffused with grey; pectus and ventral surface of abdomen whitish tinged with rufous, the legs whitish tinged with grey-brown. Fore wing pale brownish grey, the costal area, the area beyond the cell, and the terminal area whiter; a dark brown antemedial mark on costa and oblique black striga from costa; a black point in middle of cell with black streak beyond it in discal fold, with white spots above and below it; the veins on costal area towards apex white defined on outer side by slight black streaks; the postmedial area with black streaks on veins 4 to 1 and on inner margin, and short streaks on veins 7 to 5 before the subterminal line which is black defined on outer side by white, strongly excurved between veins 5 and 2, then strongly angled inwards at submedian fold and outwards at vein 1; a black terminal line; cilia with fine white lines near base and tips. Hind wing semihyaline white with a faint brown tinge; a brown terminal line; cilia white with a brown line near base.

TRANSVAAL, White R. (*Cooke*), 1 ♀ type. *Exp.* 26 mill.

Veldticola striatella, sp. n.

Head and thorax purplish grey, the head with some black scales, the tegulæ, patagia, and dorsum of thorax with black streaks, the antennæ black, the palpi blackish, whitish above; abdomen rufous with the basal crests grey; pectus, legs, and ventral surface of abdomen white and blackish. Fore wing purplish grey, the veins streaked with black to the subterminal line and black streaks in discal and submedian folds to end of cell, a white streak above median nervure; antemedial line represented by a white line to median nervure angled outwards below costa and a diffused black mark defined on inner side by white above inner margin; subterminal line white defined on each side by black, slightly excurved from vein 7 to submedian fold; a black terminal line and fine yellowish line at base of cilia. Hind wing semihyaline white with a faint brownish tinge; a brown terminal line; cilia pure white with a fine yellowish line at base followed by a brown line.

The male on underside with black androconia on costal area of both wings to beyond middle.

Transvaal (*Pead*) 1 ♂ type, Pretoria (*Janse*) 1 ♀. *Exp.* 24 mm.

Veldticola nebulosella, sp. n.

♀. Head and thorax grey-white, the tegulæ with some black scales, the patagia with black streaks, the antennæ black, the palpi white and black with a black patch near extremity of second joint; abdomen pale rufous with some dark scales, the crests on basal segment grey; pectus and legs black mixed with white, the tarsi tinged with white. Fore wing grey-white thickly irrorated and clouded with dark brown; an antemedial black shade with black streaks on it at subcostal and median nervures and a diffused black patch at inner margin; a slight white streak above median nervure except towards base; black spots defined by white except on inner side at extremities of subcostal and median nervures and a black spot with white before and beyond it at middle of vein 1; subterminal line white defined on each side by diffused black, rather indistinct, excurved from vein 7 to submedian fold; a terminal series of ill-defined black points; cilia with a fine black line near tips. Hind wing semihyaline white, the costal area tinged with brown; a brown terminal line and line near base of cilia.

Transvaal, Pretoria (*Janse*), 1 ♀ type. *Exp.* 26 mm.

Veldticola irrorella, sp. n.

♀. Head, thorax, and abdomen pale rufous irrorated with black, the antennæ pale red-brown; pectus and ventral surface of abdomen white tinged with rufous. Fore wing pale rufous thickly irrorated with black; traces of a pale antemedial line, slightly excurved between discal and submedian folds; a terminal series of prominent black points. Hind wing semihyaline white with a faint red-brown tinge; a brown terminal line and line near base of cilia.

TRANSVAAL, White R. (*Cooke*), 1 ♀ type. *Exp.* 28 mm.

Veldticola macra, sp. n.

♀. Head and thorax grey tinged with red-brown and slightly irrorated with black, the antennæ slightly tinged with black, the palpi with the extremity of second joint and the third joint darker; abdomen grey tinged with red-brown; pectus, legs, and ventral surface of abdomen grey tinged with red-brown and irrorated with black. Fore wing grey rather sparsely irrorated with black, the cell and area just beyond it whiter, the inner and terminal areas tinged with red-brown; antemedial line double, blackish filled in with whitish, rather oblique to submedian fold and angled inwards at vein 1; a black discoidal bar; subterminal line double, blackish filled in with whitish, oblique to discal fold and excurved at middle and vein 1; a rather punctiform black terminal line from just below apex to vein 2, and a whitish line at base of cilia. Hind wing whitish tinged with red-brown, a dark terminal line and line near base of cilia.

BR. E. AFRICA, Kinjabe (*Betton*), 1 ♀ type. *Exp.* 32 mm.

Veldticola megista, sp. n.

Head and thorax fuscous-brown mixed with pale bluish grey, the antennæ dark brown, the basal joint above and ridge of scales in male whitish; abdomen whitish and fuscous-brown with pale red-brown segmental bands; pectus, legs, and ventral surface of abdomen fuscous-brown and white, the tarsi blackish tinged with white. Fore wing bluish white tinged with brown and irrorated with black. Antemedial line rather diffused black-brown defined on inner side by white, oblique, angled outwards at discal and submedian folds and inwards at vein 1; two large black-brown discoidal points; subterminal line white defined on inner side by black-brown and less distinctly on outer, oblique to discal fold where it is angled inwards, angled outwards at middle, then oblique and dentate; a terminal series of black points. Hind wing semihyaline white, the veins of terminal half tinged with brown, the apical area suffused with brown; a blackish terminal line; cilia with a fuscous line near base and tinged with fuscous at tips.

MASHONALAND, Umtali (*Janse*), 1 ♂, 2 ♀ type. *Exp.* 34–42 mm.

Genus EMMERITA, nov.

Type, *E. mirandella.*

Proboscis fully developed; palpi upturned, broadly scaled, the second joint reaching to about middle of frons, the third short; maxillary palpi dilated with scales, in male the palpi hollowed out to receive the large brush-like maxillary palpi; frons smooth; eyes large, round; antennæ of male somewhat laminate and almost simple, the shaft with sinus at base containing a double ridge of scales; hind tibiæ with small tufts of hair above at base and extremity; abdomen with small flattened dorsal crests on two basal segments. Fore wing rather narrow, the costa arched, the apex rounded, the termen evenly curved; vein 2 from well before angle of cell, oblique; 3 from just before angle; 4–5 approximated for some distance, not in line with the median nervure; 6 from upper angle; 8, 9, 10 stalked; 11 from cell. Hind wing with the cell about half the length of wing, the lower angle produced; vein 2 from near angle of cell; 3 approximated for some distance to 4–5 which are strongly stalked; the discocellulars curved; 6–7 shortly stalked; 8 not anastomosing with 7.

Emmerita mirandella.

Meroptera mirandella, Rag. Rom. Mém. vii. p. 313, pl. 47. f. 4 (1893); Dyar, Cat. Lep. N. Am. p. 423.

U.S.A., Colorado.

Genus STYPHLORACHIS, nov.

Type, *S. mesophæa.*

Proboscis fully developed; palpi upturned, the second joint hardly reaching to vertex of head and rather broadly scaled in front, the third rather long and thickly scaled; maxillary palpi filiform; frons smooth; eyes large, round; antennæ somewhat laminate and almost simple; tibiæ smoothly scaled. Fore wing rather narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell, curved, 3 from just before angle; 4–5 from a point; 6 from upper angle; 8–9 stalked; 10–11 from cell; the upper side with an antemedial ridge of raised scales except towards costa. Hind wing with the cell about one-third length of wing; vein 2 from before angle of cell; 3 from angle; 4–5 strongly stalked; the discocellulars curved; 6–7 shortly stalked; 8 anastomosing with 7.

Styphlorachis mesophæa, sp. n.

♀. Head and thorax dark olive-brown mixed with some whitish, the antennæ dark brown, the palpi dark brown mixed with white; abdomen pale olive-brown with whitish segmental lines; pectus and legs white mixed with blackish, the tarsi black ringed with white. Fore wing olive-brown suffused with dark brown; an oblique triangular white patch irrorated with black from costa to inner margin before the broad antemedial ridge of silvery blackish scales which is followed by a conical patch of cupreous-red and olive before the dark antemedial line which is oblique to submedial fold and slightly incurved at vein 1; the medial costal area blackish; an obliquely curved blackish discoidal bar with an oblique triangular white patch thickly irrorated with blackish from postmedial part of costa to its outer side; subterminal line whitish defined on each side by diffused blackish, incurved to vein 5, then very slightly waved and incurved below vein 3; a terminal series of black points and white line at base of cilia. Hind wing white tinged with brown especially on the veins and costal area; a brown terminal line and line near base of cilia.

Br. C. Africa, Lake Nyasa (*de Jersey*), 1 ♀; Transvaal, White R. (*Cooke*) 1 ♀, Barberton (*Janse*) 4 ♀ type. *Exp.* 18 mm.

Genus Myelodes, nov.

Type, *M. jansei.*

Proboscis fully developed; palpi downcurved, extending about twice the length of head and thickly scaled; maxillary palpi dilated with scales at extremity; frons smooth; eyes large, round; antennæ of female laminate and almost simple; hind tibiæ fringed with hair above. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell; 3 from before angle; 4–5 stalked; 6 from well below upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell more than half the length of wing; vein 2 from long before angle of cell; 3 from angle; 4–5 strongly stalked: the discocellular curved; 6–7 from upper angle; 8 not anastomosing with 7.

Sect. I.—Fore wing with veins 4–5 strongly stalked.

Myelodes flavimargo, sp. n.

♀. Head and throat silvery white, the antennæ tinged with fuscous, the palpi orange-yellow; abdomen orange-yellow, the basal segment white; pectus, legs, and ventral surface of abdomen white tinged with yellow, the fore legs streaked with black above, the mid-femora black above at extremity. Fore wing silvery white, the costa, termen, and cilia yellow, the costal edge black towards base; small antemedial black spots on median nervure and vein 1, two discoidal spots and a curved subterminal series; a terminal series of black points except towards apex and tornus. Hind wing pale yellow. Underside of fore wing yellow suffused with black except on inner and terminal areas.

TRANSVAAL, Pretoria (*Janse*), 2 ♀ type; BASUTOLAND, Masite (*Weigall*), 1 ♀. *Exp.* 22 mm.

Sect. II.—Fore wing with veins 4–5 very shortly stalked.

Myelodes jansei, sp. n.

♀. Head white with a black bar above the frons, the antennæ black, barred with white above, the palpi with the second and third joints black above, except at tips, the maxillary palpi black, white at tips; tegulæ golden-yellow, with black spots at base; thorax slate-grey with some black on prothorax; abdomen golden-yellow; pectus yellow, white in front; legs white, the fore legs black above, the mid-femora and base of tibiæ black above, the hind legs black mixed with white, the tibiæ fringed with yellow hair above, the spurs and tarsi black, the latter ringed with white. Fore wing silvery white to median nervure and vein 5, the costal edge black, expanding with a patch at base; the inner half o wing slate-grey, extending on terminal area to near apex; a small black spot below base of cell; antemedial spots in the cell and on median nervure and vein 1, the spot in the cell nearer the base; two discoidal spots, a curved subterminal series to vein 2 and a slight spot on vein 1, a terminal series. Hind wing golden-yellow; a terminal fuscous line to vein 4. Underside of fore wing fuscous, some white below costa towards base and some yellow in upper part of cell except towards base, a diffused black postmedial spot on costa with some whitish suffusion before and beyond it.

S. Rhodesia, Umtali (*Janse*), 1 ♀ type. *Exp.* 46 mm.

Genus Meyrickialis, nom. nov.

	Type.
Meyrickiella, Hmpsn. Rom. Mém. viii. p. 86 (1901), nec Berg, 1898	*homosema.*

Proboscis fully developed; palpi upturned, the second joint reaching to vertex of head and moderately scaled, the third short and thickly scaled; maxillary palpi filiform; frons rounded and thickly scaled; eyes large, round; antennæ of male somewhat laminate and almost simple, the shaft with a sinus at base containing a large ridge of scales; fore and mid tibiæ smoothly scaled, the hind tibiæ with a small tuft of hair above at extremity. Fore wing narrow, the costa slightly arched, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell, curved; 3 from just before angle; 4–5 strongly stalked; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about one-fourth length of wing; vein 2 from well before angle of cell; 3 and 5 from angle, 4 absent; the discocellulars erect; 6–7 stalked; 8 anastomosing with 7.

Meyrickialis homosema.

Hypophana homosema, Meyr. Trans. Ent. Soc. 1887, p. 264; Rag. Rom. Mém. viii. p. 86, pl. 26. f. 15.

W. Australia; N.S. Wales; S. Australia.

Genus Anousterunia, nom. nov.

	Type.
Pogonophorus, Saub. Verh. Ver. Naturw. Unterh. Hamb. x. p. 63 (1899), nec Latr. Coll. 1802	*tancrei.*
Pogonotrophus, Saub. Verh. Ver. Naturw. Unterh. Hamb. x., Corrig. (1899), nec *Pogonatropha*, Zell. Lep. (1852)	*tancrei.*

Proboscis fully developed; palpi porrect, in male extending about one and a half times length of head, in female about the length of head, almost hidden by long hair; maxillary palpi minute; head hairy, the frons without prominence; eyes rather small in male, small in female, round; antennæ of male typically with fasciculate cilia; tibiæ fringed with hair above. Fore wing narrow, the apex rounded, the termen evenly curved; vein 2 from towards angle of cell; 3, 4, 5 separate; 6 from upper angle; 8–9 stalked; 10–11 from cell. Hind wing with the cell about half the length of wing; vein 2 from well before angle of cell; 3 and 5 from angle, 4 absent; the discocellulars angled; 6–7 from upper angle or shortly stalked; 8 typically anastomosing with 7.

Sect. I.—Antennæ of male with fasciculate cilia; hind wing with veins 6–7 from upper angle of cell, 8 anastomosing with 7.

Anousterunia tancrei.

Pogonophorus tancrei, Sauber, Verh. Ver. Naturw. Unterh. Hamb. x. p. 63 (1899); Staud. Cat. Lep. pal. ii. p. 25.

W. TURKESTAN.

Sect. II.—Antennæ of male laminate and minutely ciliated; hind wing with veins 6–7 shortly stalked, 8 not anastomosing with 7.

Anousterunia alticola, sp. n.

♂. Head and thorax black-brown with a slight rufous tinge; abdomen black-brown, the anal tuft grey-white; pectus and legs black-brown, the tarsi tinged with grey-white. Fore wing grey-white mixed with very dark red-brown, the discal fold beyond the cell and submedian fold with obscure rufous streaks; antemedial line strong, white defined on outer side by rather diffused black, oblique and slightly excurved; an oblique black discoidal bar; subterminal line white strongly defined on inner side by black, rather oblique and slightly excurved at middle; a terminal series of rather diffused black points; cilia whitish at base, pale red-brown at tips. Hind wing blackish tinged with grey, the costa to near apex and the cilia except at base whiter. Underside greyish suffused with fuscous, the terminal area of fore wing and the apical area of hind wing greyer; fore wing with oblique black postmedial line slightly excurved at middle.

KASHMIR, Rupshu, 17,500 feet (*Avinoff*), 1 ♂ type. *Exp.* 20 mm.

IV.—*New* Derbidæ *from Sierra Leone* (Homoptera Fulgoroidea).

By F. Muir.

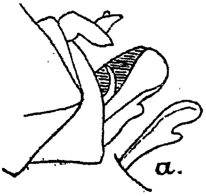
The species mentioned below were submitted to me, along with others, for identification by the Imperial Bureau of Entomology. The types will be placed in the collection of the British Museum (Natural History).

Cedusa nigripes, sp. n. (Fig. 1.)

Male.—Length 1·8 mm.; tegmen 2·5 mm.

Shoulder-keels not very large; subantennal plate longer than wide; length of frons twice the width, no median carina; width of vertex at base twice the length, base wider than apex. *M* with five apical veins, viz., 1, 1 *a*, 2, 3, 4; forking of *Sc*+*R* and *Cu* about level; cross-veins near nodal line, apical cross-veins subparallel to apical margin.

Lateral and ventral margins of pygofer entire, slightly curved; anal segment small, apex rounded; genital styles small, apex round, a curved spine near base on dorsal margin, inner margin produced into a round process about the middle.



1

Cedusa nigripes, sp. n.

Lateral view of male genitalia; *a*, ventral view of left genital style.

Head and thorax stramineous; middle of clypeus and frons fuscous, thorax darker; labium dark fuscous; front legs dark fuscous, hind legs with the femora and first two tarsi stramineous, rest fuscous; abdomen reddish brown. Tegmina hyaline, slightly fuscous or dirty stramineous, veins darker; wings hyaline with brown veins.

Female.—Length 1·8 mm.; tegmen 3 mm.

Similar to the male in build and colour. Pregenital plate angularly produced from sides to middle.

Hab. Sierra Leone, Kailahun, "ex Piasaara" (*E. Hargreaves*, May 1928), described from four males and four females.

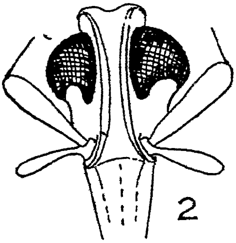
Phenice bicornis, sp. n. (Figs. 2, 3.)

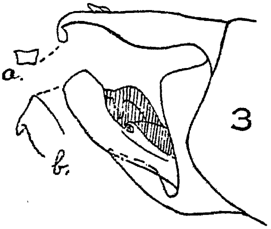
Male.—Length 2·9 mm.; tegmen 5·3 mm.

This species differs from all the others of the genus in having the basal segment of the antenna produced into a long, narrow, flattish process. Antennæ about as long as the frons, the process from the basal segment not so long as the second segment. Carinæ on clypeus obscure. Basal *Ms* furcate at the spot where *M–Cu* cross-vein joins it.

The anal segment truncate at apex, which is curved ventrad; medio-ventral process large, lanceolate; genital styles long, inner margins entire, slightly curved, outer margin produced into a small curved spine slightly before middle, apex truncate, the inner corner slightly produced.

Stramineous; slightly darker over frons and antennæ. Tegmina hyaline with light fuscous marks, over base of clavus extending over base of radial and subcostal and apical half of costal, another mark from apex of clavus to base of *Ms* 1; a darker mark over cross-vein of *Cu* extending into membrane, the cross-veins of *Ms* and *R–M* dark, veins otherwise light. Wings hyaline, slightly fuscous.





Phenice bicornis, sp. n.

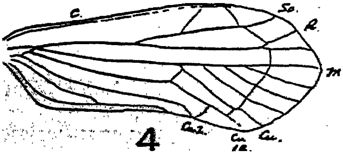
Fig. 2.—Front view of head.
Fig. 3.—Lateral view of male genitalia; *a*, apex of anal segment; *b*, apex of genital style.

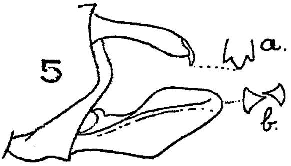
Female.—Length 3·7 mm.; tegmen 6·9 mm.

Antennæ slightly shorter than in male, and the process on the base also shorter. The ovipositor longer than is general in Derbidæ. Pregenital plate with hind margin angularly produced from middle to sides.

Colour similar to male, but with the dark marks over *Cu* and *M* cross-veins darker.

Hab. Njala, Sierra Leone; "at light" (*E. Hargreaves*, Dec. 1928; August, December, 1928). Two males and one female.





Patara hargreavesi, sp. n.

Fig. 4.—Right tegmen.
Fig. 5.—Lateral view of male genitalia; *a*, apex of anal segment; *b*, apices of genital styles.

Patara hargreavesi, sp. n. (Figs. 4, 5.)

Male.—Length 1·9 mm.; tegmen 2·8 mm.

This differs from the typical species of the genus in having a small subquadrate subantennal plate situate more behind than beneath the antenna. The venation of the tegmen is similar to that of *Patara pattersoni* *, the only other species of the genus so far reported from Africa. They both differ from the type, *P. guttata*, in the *Cu* and in having an extra *Ms*, but I consider that they must both come into the genus.

Antennæ not as long as the frons, thick and wide; a small quadrate plate arising from the head behind the antenna, the distal margin bearing hairs. Vertex triangular, small; frons narrow.

Anal segment long, narrow, the apex produced into three small processes, the middle one curved downward. Genital styles long, fairly narrow, widest about middle, where the inner margin is angular, apices pointed and curved inward.

Shiny black; clypeus and legs yellow. Tegmina and wings black with a reddish tinge; apical portion of costal margin reddish, a small light mark at the apices of each vein entering the apical margin.

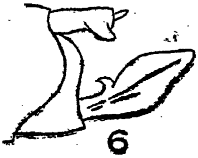
Female.—In size and colour similar to the male. Pregenital plate angularly produced from sides to middle, the two sides of the projecting angle slightly sinuate.

Hab. Kenema, Sierra Leone, on Oil Palm (*E. Hargreaves*, May 1928). Three males and three females.

Patara elæidis, sp. n. (Fig. 6.)

Male.—Length 1·5 mm.; tegmen 2·7 mm.

The antennæ about as long as the frons, broad and flat; no subantennal plate. The venation of tegmen similar to *P. guttata*, with three median sectors and only one branch to *Cu*.



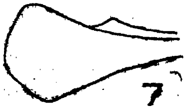
6

Patara elæidis, sp. n.
Lateral view of male genitalia.

Anal tube short, the apex produced into two small, conical processes, one on each side. Ventral margin of pygofer straight,

---

* This was omitted from the list published by the writer in Ann. & Mag. Nat. Hist. (10) i. p. 498. (Fig. 7.)



7

Patara pattersoni.
Right genital style.

sides slightly curved; genital styles large, sublanceolate in outline, a small curved spine on dorsal margin near base.

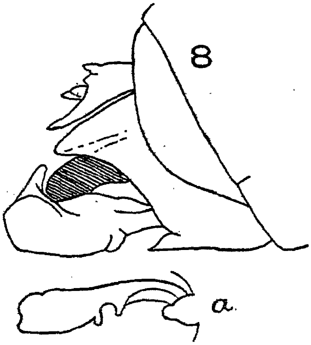
Frons, vertex, antennæ, and thorax yellow, the mesonotum darker; clypeus brown; front legs fuscous, middle and hind legs yellow; abdomen brown. Tegmina and wings fuscous with darker veins, the apical cells of tegmina lighter.

Hab. Sierra Leone, Kenema, on Oil Palm (*Elæis guineensis*, Jacq.) (*E. Hargreaves*, May 1928), one male.

There are three other specimens of this genus, representing two species, but as one is a damaged male and the others females I refrain from describing them.

Zoraida flavocostata, Dist.

This species was described from one female from Kola River, Portuguese East Africa. The specimens before me, which I place in this species, are from Sierra Leone, Njala (*E. Hargreaves*, Dec. 1927 and April 1928). I figure the male genitalia for comparison with the male from the type-locality.



Zoraida flavocostata ?, Dist.

Lateral view of male genitalia; *a*, ventral view of right genital style.

V.—*On the Multiple Tumours* (Lymphocystis) *of Plaice and Flounders.* By Emeritus Professor W. C. M'Intosh, M.D., D.Sc., LL.D., F.R.S., Gatty Marine Laboratory, University of St. Andrews.

[Plates I.–IV.]

This appears to be the affection mentioned by Dr. Lowe *, who frequently found it in flounders from the Ouse, Norfolk. He described it as a peculiar skin disease resembling epithelioma, large fungus growths cropping out over the whole body. The granulations are large and roe-like, consisting of large nucleated cells under the microscope.

---

* Trans. Norfolk & Norwich Nat. Soc. 1873–74.

In the estuary of the Thames in 1883 many common flounders were thus attacked, besides being infected with *Caligi*. Like the haddocks suffering from gill-parasites and the green cod from *Caligi*, the fishes were generally out of condition.

In the third Annual Report of the Fishery Board for Scotland a note on these tumours affecting plaice at St. Andrews was made as follows:—

"The coloured surface of the fish was crowded with the small rounded tumours which resembled shot. They also occurred on the dorsal, ventral, pectoral, and caudal fins, and on the white surface. They are firmly fixed to the skin and give pain to the animal when interfered with. Moreover, they are vascular, free hæmorrhage occurring when they are injured. The isolated tumours range from 1·7 mm. to 1 mm. or less. The larger masses, when bisected, show a series of smaller areas, the whole being composed of multiple tumours [cells] mostly of the same size. When cut into in the fresh state, a whitish-creamy substance exudes, which, under a power of 400 diameters, is minutely granular, no distinct cell-elements being visible, though fine fibrillæ occur throughout the field as if the fluid were coagulable. In section [with a scalpel] the large tumours present a series of loculi, or spaces filled with the granular creamy fluid. Each chamber is cystic, presenting a firm hyaline wall of considerable thickness, within which is the granular contents. The stroma exterior to the hyaline coat is chiefly fibro-granular. Amongst the larger cysts are numerous smaller forms in course of development, the thick, translucent, hyaline wall being conspicuous" *.

Further examination † of a large multiple tumour projecting from the mouth of a flounder at St. Andrews showed that the fluid escaping from "the cut surface contained masses of small granular cells with distinct nuclei—these apparently being external to the encysted bodies forming the tumour, for the contents of the cysts were mainly granular."

Mr. George Sandeman ‡ subsequently examined these tumours at St. Andrews in 1893, observing that "an individual cyst is surrounded by a hyaline membrane, and is in close connection with the inner surface of the skin, which is always unbroken over it. The pearly-white sphere has no deep attachment, but lies in loose connective tissue. On pressure it bursts, and exudes a white, creamy, granular substance. . . Their enclosing membrane is hyaline and apparently structureless (pl. xvii. fig. 5) but for a radial striation in the inner layer, which gives it a resemblance to an egg-membrane with a *zona radiata*. . . It gives the staining reactions characteristic of yolk. . . The larger masses vary in size and shape, ranging from a tumour formed of two or three cysts to one an inch in length and half an inch in diameter. They may be broad at the base, but are usually narrow and projecting, sometimes even pedunculated." Between the cysts "is a varying amount of tissue, especially abundant near the base of the tumour, and consisting of fibrine and leucocytes, or of more or less advanced connective tissue, in one case of myxomatous tisssue. . . Young blood-vessels are usually present." The author thought they were unlike any known Protozoon or Protophyte, and mentions that the present writer once found *Diplozoon paradozicum* in one of the tumours.

---

* S. F. B. Rep., Appendix, pp. 66–67, 1885.

† *Ibid.* No. 4, Appendix, p. 214, 1886.

‡ *Ibid.* for 1892 (1893), pt. 3, pp. 391–392, pl. xvii. figs. 1–7.

Dr. Woodcock *, in his careful description, observes, in regard to the cysts in the mesentery, that they are smaller than those outside—never exceeding 1 mm. in diameter. He supposes that when small they pass into the blood-vessels (capillaries) or lymph-channels from the gut, and then grow and encyst, "since in sections they are surrounded by a space." He found all the other viscera normal, so that the hosts did not appear to be seriously harmed. The cysts increase in size, but each remains a single cell, and he found no trace of cell-nuclei nor of cell-division. In his fig. 3 (pl. iii.) he gives a section, minutely covering the structurless investment with dots (never seen by the writer), the "capsule being surrounded by a layer of amœbocytes closely aggregated." Next comes a thick deeply-staining zone of a finely granular nature, the greater part of which gives the organ its character. "Centrally is a huge nucleus with a very thin nuclear membrane (from a cyst underneath the skin), and in it several nucleoli or karyosomes (since they retain the chromatic stain)." He considered these bodies unlike any known Protozoan, and he gave the name *Lymphocystis johnstonei* to them. He considered the tumours masses of cysts "with, of course, a little vascular connective tissue between and around them."

A. S. Awerinzew † procured a flounder with this sporozoan parasite in the mesentery, liver, ovary, as well as in the skin of the fish. The shape was generally ovoid, and it measured from 1 to 3 mm. in diameter. Out of 109 flounders 19 were affected, or 11 per cent. He alluded to the observations of Johnstone and Woodcock, pointing out that the Myxosporidian had the structure of the genus *Henneguya*, and thus he called Woodcock's form *H. johnstonei*. He found the youngest stage disk-shaped and measuring 0·060 to 0·090 mm., with an ectoplasmic tail (0·011 mm.), a cirrus of endoplasm, and a nucleus in the endoplasm. He goes into detail in regard to nuclei and nucleoli and their staining. The spore subsequently loses its tail. He did not allude to the structure of the wall of the tumour.

Two papers on the allied type, *Glugea*, by R. Weissenberg ‡ appeared in 1911 and 1913. In the first of these an account is given of an attack of the parasite on the central nervous system of *Lophius piscatorius*, and descriptions and figures closely approach those met with in the "multiple tumours" of plaice and flounders; yet, so far as the investigations have gone, none of the minute spores characteristic of *Glugea* have been encountered, though it is possible such early stages have been passed before the introduction of the parasite into the tumour. Moreover, Weissenberg shows that the capsule of the young *Glugea* is uniformly smooth amidst the nerve-cells; and he alludes to the budding chain (Sproskettten) of the schizont in the outer zone of the young *Glugea*.

---

* Rep. xii. Lancashire Sea-Fisheries Lab. 1903, p. 63.

† "Leiter der mariner Biol. Murman," Zool. Anz. Bd. xxxi. no. 26, July 9, 1907 (with text-figs).

‡ Arch. f. Micros. Anat. Bd. lxxviii. p. 383, Taf. 18 & 19; *ibid.* lxxxii. p. 81, Taf. iv.-vii.

In the second paper he treats of the minute structures of *Glugea anomola*, Moniez, and of *G. hertwigi*, Weissenberg, the former occurring in the stickleback and the latter in the smelt. He deals exhaustively with both species, and figures the spores of *G. hertwigi*.

In a plaice procured in St. Andrew's Bay on the 15th August, 1895, a tumour nearly half an inch in diameter was situated behind the left eye and attached to the surface by a narrow pedicle (Pl. I. figs. 1 & 2), and thus had a certain amount of motion (Pl. I. figs. 1*a*–1*b*). Externally the surface was everywhere raised into the little eminences from the development of the egg-like cysts internally. On cutting through the tumour the entire contents consisted of these cysts, which varied in size from a quarter or less to 5 or 6 mm. In structure the surface of the section presented a fibro-granular matrix surrounding the cystic bodies, each of which had a structureless gelatinous investment of varying size, the interior being opaque and granular. On the left (pale) side of the fish (Pl. I. fig. 1 *a*) four flattened circular bodies were present, two towards the ventral and two near the dorsal margin and about half an inch from the dorsal fin. Each of these had the same cystic contents surrounded by the fibro-granular matrix. Further, besides the larger cysts in the sections of the fresh tissue, there were groups of much smaller forms, some of a nearly uniform size as well as others scattered singly, and such necessarily raised the question as to their origin. No sign of the development of these smaller bodies in the larger has ever been seen; nor can they arise from the fibro-granular matrix. In looking over the field of a preparation, a more distinctly cellular structure was once met within, the cyst, apparently of one size over the whole area; but such may have been due to preparation and pressure. No distinct gelatinous investment was seen in these cases. The appearance of this cyst resembled that figured by Weissenberg * in the upper part of the lower (right) cyst in fig. 7 (pl. xix.) in *Glugea lophii*, Doflein.

The field of a section of the entire turmour has the larger cysts occupying most of the space and surrounded by the general fibro-granular tissue, in which also groups of the smaller cysts and blood-vessels occur. The smaller (developing) cysts have no definite distribution, occurring throughout sometimes in groups of about 20 or more (Pl. II. fig. 14). This represents a group of a dozen small cysts nearly of equal size, a larger one being below. It is seldom that so considerable a series of almost uniform size is met with, irregular sizes (as in Pl. III. fig. 8) being more common. They may even reach the proximity of the investing layer, though such is generally the seat of the larger cysts. The latter show within the translucent gelatinous coat the "Plasmaschale" of Weissenberg, a mass of granules, whilst in the centre is a gelatinous area often with numerous processes or rays. Sometimes a median cyst (Pl. I. fig. 1) has a separate opaque granular area and a more translucent gelatinous area, as if the whole had undergone division, but such appears to be due to changes during the preparation, which also cause the gelatinous investment ("ectocyst"; "Plasmaschale," Weissenberg), often to shrink into a linear belt in section, and it is occasionally doubled or folded, each fold separated by a layer of granules (Pl. I. fig. 2). In some of the smaller cysts amœboid forms akin to those described by Awerinzew appear (Pl. I. figs. 4 & 4 *a*).

---

* Arch. f. Micros. Anat. Bd. lxxxviii. 1911.

The tumour is highly vascular, and the field contains many blood-vessels—large and small—within some granular blood (corpuscles) or opaque bodies. Thus a minute larval form such as that described by Awerinzew might readily be introduced, and, indeed, in the smallest or first stage of the cyst is apparently present; once introduced, the larva, in the midst of rich nourishment, would seem simply to enlarge by compressing the surrounding stroma which alone forms its investment (figs. 5, 5 *a*, & 6), the former representing a blood-vessel containing a foreign body stained, the latter showing a pale investment. Occasionally the section of a vessel presents within its definite deeply-stained wall only a translucent, finely-reticulated substance; but, on searching its further course, corpuscles appear—thus demonstrating its nature. Such a vessel would contain a parasite of considerable size.

Some of the minute cysts show only an indefinite border to the cavity and a small circle of the structureless ectocyst (the gelatinous layer), within which are a few granules. In the most minute there is simply a black (stained) centre without an evident ectocyst, or perhaps only a trace of it at the circumference. Such is readily distinguished from a small blood-vessel by the well-defined wall of the latter—whereas the cystic wall is only part of the surrounding stroma (Pl. I. fig. 12 *a*). The occurrence of the smaller cysts in groups here and there may indicate occasional epochs of infection. The next stage to fig. 12 (Pl. I.) is the formation of the structureless ectocyst with the densely granular centre; the gelatinous substance in the early amœboid stage seems to be rapidly separated to form this investment.

The so-called fibro-granular matrix around and between the cysts appears to be formed of fine strands of the gelatinoid substance which plays so important a part in these parasites. The addition of the stain covers the field of these strands with multitudes of minute dark granules which vary in size and shape and seem to be due to the action of the stain on the constituents of the fibres themselves, being minute in much of the stroma, coarser and in rows in other parts. This tissue supports the numerous blood-vessels—large and small—throughout the tumour, and it is curious to note its divergent condition in the tumour on the tail.

When two adjoining cysts are cut obliquely, it is clearly shown that the narrow process of the stroma around and between them forms no special capsule for each cyst—a fact not in accordance with Dr. Woodcock's statement and figure * in those from the mesentery. Each cyst, he states, lies in a space "representing an enlarged capillary or lymph-chamber. It is surrounded by a layer of amœbocytes rather closely aggregated." In a more highly magnified section of the same cyst (fig. 6) he shows the external layer of a "thick, faintly-staining structureless membrane (*ect.*). Next comes a thick zone, more deeply staining, finely granular, the greater part of which presents a most unusual appearance and gives the organism its remarkable character. Centrally is what can only be a nucleus (N.). In each nucleus are several nucleoli, or rather karyosomes, since they retain chromatin stain. The nuclear membrane is very thin and irregular, and sometimes seems only a boundary between the nucleus and the inner limit of the critical region."

In studying the various sections † after staining with iron hæmatoxylin, the tumour presents externally a superficial series of circular areolæ (Pl. I. fig. 7 *a*), which vary a little in size in the stroma. These project in some cases as clear vesicles on the free edge, and give a character to the surface. The deeper part (Pl. I. fig. 7 *b*) of this thick layer is minutely cellular throughout, forming a compact investment. Within is a fibroid layer (Pl. I. fig. 7 *c*) profusely dotted with black points (stained), especially on its inner edge, so that it forms a nearly continuous black border against which the paler ground-tissue of the tumour rests—this, as a rule, intervening between the walls of the cysts and the inner cortical (dermal) layer. The subdermal fibroid layer might be mistaken for a muscular coat, but it is essentially different, being composed of fibrils (Pl. IV. fig. 18), which here and there have dilatations and contractions as if protoplasmic—which it really seems to be, though the continuous arrangement of the more or less separate fibrils is striking. The coat is, perhaps, less developed in this tumour than in that attached to the tail, as will subsequently be shown.

The cysts (Pl. I. figs. 2, 4, & 7 and Pl. II. figs. 13, 14, & 15) present diverse aspects in the sections, and the translucent, friable, gelatinous investment is much altered. In some the contents are deeply stained with large black granules throughout, or with rows of granules like chains, whilst the cyst may be split into two parts, an outer part of dark granules and a central gelatinous mass with various processes only slightly stained, or the whole area forms a network of fibrils with scattered dark granules. Occasionally the gelatinous ectocyst forms a double loop fused in the centre, each chamber thus being separated (Pl. II. fig. 13). In certain cases it may be that rupture of the interstitial tissues takes place, so that the ectoplasm of two adjacent cysts fuses. Besides the characteristic translucent investment the larger cysts have the same substance in their interior, and it gives rise to numerous striking figures—from solid central masses to brush-like or arborescent strands and intricate reticulations, the latter affecting in some instances a double chamber (Pl. IV. fig. 16). The size of the cysts ranges from ·5 mm. (Pl. I. fig. 12) to 8 or 9 mm. or more. Early stages of the cysts are also shown in Pl. II. (fig. 14) with undefined walls, and so close were they that their oval shape was probably due to pressure. A faint ectocyst appears in the upper figure. In another minute stage (Pl. I. fig. 5 *a*) the cyst was U-shaped, and no granular contents were in the section. Occasionally a cyst occurs in the section in which the central ovoid mass is separate from the gelatinoid layers, and apparently retains its shape by the nature of its substance, which consists of stained granules each surrounded by a protoplasmic investment (Pl. IV. fig. 22). Whether this was due to the effects of the preparation for section or otherwise is doubtful, but it resembled the conditions in its allies. Such appearances were unconnected with the origin of the young cysts. In the majority of the larger cysts the large stained granules form a belt externally, but they varied in size, were often devoid of a gelatinous investment, and in no case could they be identified with spores. Again, swarms of oval spores occur in Weissenberg's *Glugea* in the stroma surrounding the cysts as well as in the external region of the cyst. His vegetative and other "Kernes" likewise differ. The occurrence of the secondary capsule and general cellular condition also diverges. Thus there was an essential difference between them and *Glugea*; yet there was much in common. The subdermal gelatinoid fibrils in this form (*Lymphocystis*) are less developed than in the second form, but they have the same character. They do not, however, penetrate as large fibrils into the body of the tumour, the translucent finely granular stroma, already described, occupying the whole of the interstitial region. It is true a slight development of the coarse fibrils here and there takes place between two cysts, but it does not extend far inward. Moreover, the boundary of the narrow subdermal gelatinoid layer internally—all round—is better defined than in the form on the tail.

---

* Rep. Lancast. Sea Fish. 1904, pp. 65 & 66, pl. iii. fig. 3.

† Which I owe to the kindness of Prof. Stanley Gardiner, of Cambridge University. They were made by his assistant in the Laboratory, Mr. Drury.

Whilst no separate and definite layer intervenes between the structureless gelatinoid investment and the stroma around, the central mass often presents an entire margin, the granular contents adhering evenly exteriorly. In certain cases a distinct thin line envelops the granular contents, a feature due to the transference of the gelatinoid substance from the central region to the surface, and independently of the more conspicuous structureless investment. The histology of the cysts has been minutely studied by Woodcock, and he ends by asserting that each is an organic unit. After much discussion and comparison with *Lymphosporidium* of the brook-trout epidemic in America, he concludes "that *Lymphocystis* appears to combine, to a certain extent, Gregarine and Microsporidian characters with remarkable results."

In the preparations the cells presented numerous stained granules, large and small, and occasionally a large central "nucleus" surrounded by a dark ring; but the latter appeared to be only a phase in the arrangement of the mobile contents, and was subject to infinite variety.

Prof. Johnstone's * two slides of the same form from the skin of a sole (external to the scales) presented few and comparatively small cysts, but each had the structureless ectocyst or gelatinous investment and the granular contents. Two additional slides, from the same source, of the ovarian region of the cod (Sept. 1925) showed, in the first, part of the ovary (stained blue) with an "angio-sarcoma" in the centre (coloured red). In the delicate stroma several bodies like the Myxosporidian cysts occurred, but these and some in the tumour itself could not be identified satisfactorily. The latter differed from the true cysts in filling the space entirely, and were devoid of the characteristic ectoplasm. In the other preparation were certain large circular ova near the margin of the central tumour and in the centre of the latter itself, but they differed from the cysts. There were also certain large rounded masses, one showing a pale ectoplasm, and the mass appeared to be dividing into two, but the investing tissue was too dense and the smaller masses outside agreed with ordinary ova. The isolation of these (which stained like the tumour) and their structure differed from the conditions in the true cysts.

The Second Tumour.

The rays of the tail-fin in a plaice, from St. Andrews, of medium size were the seat of a diffuse and somewhat nodulated tumour (Pl. II. fig. 21) which extended about half an inch from the right or lower edge to the dorsal or left edge, commencing in front behind the bony skeleton and passing backward to the extremities of the rays. The thick, firm, mass fixed the rays, and somewhat distorted the fin so that its functions were much interfered with. The rays of the distorted fin were almost indistinguishable on the left base either dorsally or ventrally, but on the right they were distinct from the base to the tip for an area fully half an inch in breadth, all beyond this area being involved in the tumour both dorsally and ventrally. The complete entanglement or absorption of the rays by the tumour was noteworthy, and consequently the fin was considerably shorter on the left side and generally asymmetrical. Little could be made out with the naked eye on section beyond a uniform solid tissue, which appeared to incorporate the the rays in its substance, surrounding them with a growth of firm tissue. Microscopically the external investment was akin to the normal, and to that covering the previous Myxosporidian tumour, viz., a superficial layer of cells or vacuoles, and a thicker inner layer of minute cells abutting on a deeply-stained belt of gelatanoid fibrils beneath.

---

* I have to thank Prof. Johnstone for his kind courtesy on various occasions.

Within the foregoing is a series of cysts (Pl. IV. fig. 17), each showing a thick corrugated band that seems to be the homologue of the structureless ectoplasm of the previous form, and which frequently makes an incomplete investment, for it ends in a granular or reticulated mass at one side. In the larger cysts, however, the investment is often complete, the centre of the cyst being occupied by a translucent reticulated mass with small clear vesicles, thus differing from the condition in the previous Myxosporidian. The stained gelatinous investment (amœboid) often forms a mass at one end (Pl. IV. fig. 16). The cysts rarely extend into the dermal tissue, but lie in the subdermal fibro-gelatinoid layer, and each has its opaque band (stained), which occasionally is spirally rolled. In certain spaces, again, large masses of the gelatinoid substance occur near dense fibroid growths in the interstitial tissues, thus wholly differing from the condition in the previous form.

The subepidermal gelatinoid layer forms considerable offshoots here and there with the cysts in it; indeed, it seems to be the only tissue in which the cysts are, and it always has a coarse fibrillar aspect from the parallel threads or chain-like tissue. These fibres show constrictions and dilatations, especially on the inner border of the subepidermal layer (Pl. IV. fig. 18). The occurrence of these slender parallel fibrils of the gelatinoid substance throughout the entire tumour is characteristic, and they sometimes lie in the centre of 10 or 12 cysts, processes passing between them.

In the sections the subepidermal layer of fibrils occasionally throws out a leaf-like ridge having very fine ramifications of its fibres (Pl. IV. figs. 3 & 19), a central trunk at the base leading with others, which are lateral, into the ridge. The fibres inosculate with each other in their course. In some of the cysts, again, translucent reticulations (protoplasmic) radiate from a central mass.

The colour of the gelatinoid masses in the stained sections is by transmitted light slightly brown, like the belts in the cysts, whilst the other tissues are bluish, except the finely-reticulated interstitial tissue and the central reticulation of the cysts. In certain slides the outer edges of the interstitial tissue are also tinted bluish. The breaking-up of two large gelatinoid masses into finely-reticulated fringes, which may join the folded interstitial tissue, is a prominent feature, and the amalgamation is complete. The coarser gelatinoid tissue seems in this form to take the place of the finer translucent tissue forming the general stroma in the former species.

It stains slightly, but sometimes not at all in the central parts, and is thus in contrast with the subdermal and other parts of the gelatinoid fibrillar tissue.

When crushed from their position (centre) in a section on a slide, the cells of this form sometimes cling together, as in Pl. III. fig. 23, a feature not hitherto seen in the other type. Such would appear to indicate that the surrounding tissue forms a more definite boundary-wall than in the latter. The stained ectoplasm is seen in two of the cysts in the figure.

Viewed broadly, much of the area of this tumour in section is occupied by curiously folded translucent masses (Pl. II. fig. 24) with numerous small blood-vessels. The tissue, indeed, resembles the folding or doubling of endless tubes, and is probably a product of the prevalent gelatinoid tissue, which forms a border to it, and in which the blood-vessels lie. The tissue varies in appearance, being more loosely or more finely reticulated, and sometimes ending in thread-like processes at a corner. Some of the masses, again, near the opaque bands of gelatinoid substance are formed of closely-arranged fibres so that they are less transparent, the one often joining the other by a coarsely or a finely-branched border. With the exception of the blood-vessels, the entire tumour, within its investment, is constructed of the same gelatinoid tissue in its several modifications, with the addition of the Myxosporidian parasites. The presence of the latter is probably the cause of this remarkable growth, which, however, assumes, by its incorporation of the fine rays and its great vascularity, a more or less malignant aspect. It is further interesting that a somewhat finer variety of the same translucent gelatinoid tissue occurs in the interior of each Myxosporidian in the tumour. Thus a striking uniformity is maintained throughout the mass.

The walls of the large blood-vessels are formed of firm fibres, the blood-corpuscles occupying the centre, and smaller trunks are shown (Pl. II. fig. 24, *b.v.*). The tumour is throughout highly vascular, and evidently in a state of active function.

The differences between this and the former Myxosporidian rest in the greater development of the gelatinoid fibrillæ in the present form, and the substitution of the irregular strands of the same substance for the much finer fibro-granular stroma of the former tumour, as well as in the nature of the cysts with their translucent and finely-reticulated gelatinoid contents. Moreover, developing forms are there present, whereas in the tumour on the tail such are only represented by the slightly smaller processes at the margin—under the dermal layer. No minute forms or spores were seen. The facies of the two differed. The large cysts in the tumour from the tail were studded in single file along the surface with a broad belt of the fibro-gelatinoid layer internally with other cysts.

Glugea in section somewhat resembles the first-mentioned tumour; but there is no ring of spores, only the structureless ectocyst, nor is the swarm of oval spores present in the stroma between the cysts.

These tumours appear to belong to the group of Phænocystes or intercellular parasites, in contradistinction to the Cryptocystes or cellular parasites. The trophic stage seems to be amœboid, as shown in the varied shapes assumed in the sections, the gelatinous exterior often forming lobate processes, whilst the interior is granular. Nothing in the life-history, so far as known, is comparable to the complex cycle of such as the Coccidian, *Aggregata eberthi**, in which schizogony occurs in the gut of *Portunus depurator,* whilst the merozoites which penetrate the intestinal wall of the cuttlefish grow into large mero- and smaller microgametocytes.

The origin of these parasites is at present in obscurity, but it may be connected with a crustacean such as *Portunus* or an annelid like *Lagis koreni*, the latter carrying a gregariniform parasite which develops into *Eugregarinellospora lagidis.*

EXPLANATION OF THE PLATES.

VI.—*Notes on Neotropical* Pselaphidæ (*Coleoptera*), *with Descriptions of new Species.* By FRANK C. FLETCHER, Minneapolis, Minn., U.S.A.

THIS is the first of a series of short papers on South American Pselaphidæ, in which I shall give descriptions of miscellaneous new species, notes on others, and revisions of small groups of species.

Contributions to this fauna already published will be found in Ann. Ent. So. Amer. 1928, xxi. pp. 203–230; Trans. Amer. Ent. Soc. 1928, liv. pp. 69–77; and Ent. News, 1927, xxxviii. pp. 149–153.

Unless otherwise stated, all types are to be found in the personal collection of the author.

Arthmius (*Arthmius*) *scaphiger*, Sharp, Biol. Centr.-Amer. ii. 1, 1887, p. 13.

Described as coming from Mexico with query, not recorded since. There is a single male in my collection from Jalapa, Mexico.

Arthmius (*Arthmius*) *subfusus*, sp. n.

♂. Elongate, narrowed anteriorly; bright rufo-testaceous, abdomen darker; scarcely perceptibly punctulate, strongly shining; pubescence pale, sparse, and rather short.

Head quadrate, including eyes considerably wider than prothorax; eyes very large, convex, coarsely faceted; dorsal surface very smooth, evenly and slightly convex over the entire surface, no impressions or foveæ of any kind; front and epistoma evenly declivitous, continuous with the vertex; sides evenly rounded; antennal tubercles not prominent.

Antennæ slender; second segment oval; third somewhat transverse, broader at apex, produced on outer side; fourth very transverse, dilated, one-half wider than second, the inner surface somewhat concave, covered with glandular hairs; fifth of about the same form as fourth, but wider and somewhat produced on outer side, surface likewise covered with glandular hairs; sixth greatly expanded on outer side, auriculate, fully twice as broad as second, the edge fringed with dense white hair; seventh subquadrate, narrowed, not wider than second; 8 of about the same form, but slightly wider and more transverse, 9 and 10 subglobular; 9 distinctly wider than 8, 10 wider than 9, 11 elongate-conical, about equal to the three preceding together; the last three segments forming a distinct club.

Prothorax about equal in length and breadth, widest in front of middle, strongly rounded, then rapidly but evenly narrowed to base; surface smooth, glabrous, convex, not sculptured, with the usual basal transverse sulcus not prolonged at the sides.

Elytra slightly transverse, widest in apical third; humeri evident, but not pronounced; surface convex, with fine sutural striæ, but no discal striæ; punctuation consisting of minute scattered punctures, each bearing a hair.

Abdomen with last ventral large and broadly concave.

Legs modified as follows: anterior tibiæ swollen in middle and slightly notched at outer side near apex; posterior femora with a thin line of fine pale pubescence along the inner length; posterior trochanters with white hair.

Length 1·6 mm.; breadth 0·8 mm.

One male, from Jalapa, Mexico.

This species belongs in that section of *Arthmius* characterized by the modified antennæ, but it is widely different from any of the described species. The type of antennal modification is unique in the genus, and this with the unsculptured head makes this species very easy of recognition.

Arthmius (*Arthmius*) *extraneus*, sp. n.

♂. Elongate, convex, narrowed anteriorly; dark testaceous in colour; not perceptibly punctate, very shining; pubescence pale and very sparse.

Head somewhat longer than wide; width including the eyes equal to that of the prothorax; eyes moderate, coarsely faceted; vertex slightly convex, sides without margins or carinæ; a pair of very deep sharp foveæ between the eyes, closer to them than to one another; these foveæ do not give rise to a sulcus; front just behind the antennal tubercles with a pair of small shallow impressions separated only by a ridge; front evenly declivitous to epistoma; antennal tubercles distinct, but not prominent, smooth.

Antennæ slender; segments 2 to 8 all longer than broad; second oval, slightly longer than broad; third a little narrower and very slightly obconic, one-half longer than broad; 4 of same form, length, and width; 5 of same length, more obconic, distinctly wider than 4 or 6; 6 a little shorter than 4, decidedly longer than broad, of same form; 7 just perceptibly wider than 6, of same form, a little over one-half broader than it; 8 much shorter, but still distinctly longer than broad, of same form and width; 9 suboval, distinctly wider, almost one-half longer than broad; 10 about equal in length and width, much wider, widest at middle; 11 not much wider than 10, elongate-conical, equal to the two preceding together; last three forming a fairly distinct club.

Prothorax just equal in length and breadth, strongly rounded in anterior half, then rapidly narrowed to base; disk very convex, with no sculpture other than the usual transverse basal sulcus.

Elytra slightly transverse, widest in apical third; humeri distinct; disk convex, with the usual sutural striæ, three basal foveæ on each elytron, and lack of discal striæ; surface very sparsely covered with minute asperities, each bearing a hair.

Legs simple, except for the anterior, which are modified as follows: femur with an acutely margined, very deep, circular fovea in the middle of its superior surface; the exterior edge of this fovea is prolonged upwards in a point; joined to this prolongation is a long, high, finely crenulated ridge, extending from the fovea longitudinally to almost the apex of the femur; apex of tibia with a bunch of rather long, apparently glandular hairs. Middle tibia with a distinct mucro near apex; middle trochanter without trace of any but the usual pubescence.

Under surface. Metasternum with a deep longitudinal sulcus; apical ventral segment with a very deep irregular fovea in apical half.

Length 1·9 mm.; breadth ·8 mm.

Described from one male from Corumba, Matto Grosso, Brazil.

This species is very closely related to *cicatricosus* and *brevicollis*, both described by Raffray. I have not seen a specimen of *cicatricosus*, but I have one of *brevicollis* in rather poor condition from the type-locality, Minas Geraes. *Cicatricosus* was described from Central Paraguay. To elucidate the differences between the three species, I append the following table:—

Antennal tubercles smooth.

Head with a semicircular sulcus interrupted at middle. Antennal segments only slightly longer than broad. Fovea of anterior femur oblong, without longitudinal carina. Middle trochanter with slight brush of hair. Terminal ventral segment impressed almost over its entire surface, with a little tubercle at middle .... *cicatricosus*, Raff.

Head with a deeper semicircular sulcus, likewise interrupted at middle, but with a little tubercle. Segments of antennæ a little longer than broad. Fovea of anterior femur oblong, without carina. Middle trochanter normal. Terminal ventral segment with a very deep fovea at middle .... *brevicollis*, Raff.

Head without trace of sulcus, but with two very approximate foveæ in middle behind antennal tubercles. Fovea of anterior femur absolutely circular, with high crenulated crest running longitudinally. Middle trochanter simple. Terminal ventral with a broad irregular depression in apical half, occupying about one-half of segmental width; this impression is suddenly deeper at the apical margin .... *extraneus*, sp. n.

Arthmius (*Arthmius*) *rubriculus*, sp. n.

♂. Slender, narrowed anteriorly; rufo-testaceous, elytra paler; hardly perceptibly punctulate, very shining; pubescence scattered, pale.

Head subquadrate, width including eyes very slightly less than that of prothorax; sides parallel, not margined; eyes moderate, coarsely faceted; entire front and epistoma, from one antennal tubercle to the other, evenly depressed, the surface almost vertical; the surface of the front and epistoma is smooth and shining, but covered quite thickly with minute tubercles, when viewed under high power each tubercle is seen to bear a fine bristle; vertex slightly convex, with a pair of large foveæ between the eyes, no sulcus; surface smooth and shining; antennal tubercles slightly prominent, rendered so by the depression of the front and epistoma.

Antennæ rather stout; first segment simple; second oval, slightly broader than the next; 3 not much longer than broad, narrower at base; 4 of the same length, width, and form as 3; 5 a little longer, of the same form and just perceptibly thicker; 6 shorter than 5, of same width as 4 and 5; 7 more oval, of same form as 6, just perceptibly wider; 8 almost quadrate, distinctly shorter than 7; 9 oval, broader, and as long as 7; 10 of about the same length, broader, widest at middle; 11 oval, acuminate at apex, slightly longer than the two preceding together, the last three segments forming a distinct club.

Prothorax almost one-sixth broader than long, sides widest and strongly rounded in apical half, then rather gradually narrowed to base; disk convex, smooth, sculptureless except for the usual basal transverse sulcus.

Elytra slightly transverse, widest in apical third; surface convex, with the usual sutural stria and the three foveæ at base of each elytron; no distal stria; surface sparsely covered with small points each with a hair, particularly conspicuous on the interval between the sutural stria and the suture.

Legs simple, except for the anterior femora, which are modified as follows: femur with a rather deep oval fovea in apical third; exteriorly to it the femur is cut by a transverse groove or notch. Middle tibia with a short, blunt, inconspicuous mucro near apex.

Under surface modified as follows. Metasternum with a deep longitudinal groove, the edges of which are rounded. Terminal ventral segment with a deep almost circular cavity with rounded edge in apical three-fourths, and occupying about two-fifths of the segmental width. Intermediate trochanter with the usual pubescence.

Length 1·4 mm.; breadth ·6 mm.

Described from one male from Corumba, Matto Grosso, Brazil.

Rubriculus is closely related to *cruralis*, Raffray, likewise described from Matto Grosso. It may at once be known by the peculiar cavity of the front and epistoma, the lack of any cephalic groove, and the anterior femur lacking any trace of a ciliated carina.

Arthmius (*Arthmius*) *mancus*, sp. n.

♂. Elongate, slender, narrowed anteriorly; rufo-castaneous in colour; not perceptibly punctate, very shining; pubescence pale, scattered.

Head quadrate, width, including eyes, about equal to that of prothorax; eyes moderate in size, coarsely faceted; vertex moderately convex, with a pair of deep foveæ near the eyes; slightly anterior to these foveæ the front is posteriorly slightly elevated above the surface, rendering it sharply defined from the vertex, from one side of the head to the other; the entire front is almost flat and descends almost vertically, the flat surface extending completely across the head, obliterating the antennal tubercles; this flattened surface is shining and thickly covered with small tubercles; before the insertion of the antennæ, before it joins the epistoma, the front is transversely concave, but still covered with the minute tubercles; the epistoma itself is prominent, and, like the front, is covered with the tubercles.

Antennæ long and slender; first segment simple; second elongate-oval, broader than the immediately succeeding; 3 and 4 of about the same form, obconic, 3 perceptibly thicker than 4, both equal in length to 2; 5 and 6 equal in width, 5 distinctly longer than 4; 5 to 7 subcylindrical, 6 of same form as 5; 7 subequal in length to 6, just perceptibly wider; 8 just slightly longer than broad, narrower than 7; 9 distinctly broader, about equal to 7; 10 suboval, broader, widest near apex; 11 elongate-conical, a little longer than the two preceding together, the last three segments forming a distinct club.

Prothorax about equal in length and breadth; sides widest and broadly rounded slightly in front of middle, then rapidly narrowed to base; surface convex, smooth, polished, sculptureless except for the transverse basal groove.

Elytra slightly transverse, widest in apical third, convex, with the usual sutural stria and three basal foveæ on each elytron; surface smooth, sparsely covered with minute tubercles each bearing a hair, the tubercles more distinct in a single row on the interval between the suture and its stria.

Legs simple, not modified in any way; middle tibia with a mucro at apex.

Under surface modified as follows: metasternum with a deep oblong foveæ at middle; first ventral segment with a thin, posteriorly-directed ligula, the last with a deep, somewhat transverse depression occupying its entire length and most of its width; intermediate segments very short.

Length 1·4 mm.; breadth ·6 mm.

Described from one male from Corumba, Matto Grasso, Brazil.

By abdominal and cephalic structure this is a species obviously belonging in the group containing *cruralis*, *cicatricosus*, *brevicollis*, and the just-described *rubriculus*, a grouping which was made by Raffray because of the modified anterior femora of the males. It is, indeed, remarkable that *mancus* should be so close to these and have absolutely simple anterior femora. In addition, *mancus* may at once be recognized by the sharp separation between front and vertex, ligula of first ventral, much larger excavation of the last ventral, and other characters.

VII.—*The Classification of the British Carboniferous Brachiopod Subfamily* Productinæ. By Helen M. Muir-Wood, M.Sc., F.G.S.

(Published by permission of the Trustees of the British Museum.)

During the last fifteen years much has been written on the subject of *Productus*, and more detailed investigation of the many species belonging to this genus has led to its subdivision into at least twenty genera or subgenera by Thomas, Chao, Fredericks, Muir-Wood, and others. There are, however, at least three well-defined groups of species still included in the genus *Productus* (sensu stricto). Recent researches have shown that this genus should be even more precisely limited to a small group of species having a peculiar internal structure.

The genus *Productus* was described by James Sowerby (1814, 'Mineral Conchology,' i. p. 153) as "an equilateral unequal-valved bivalve with a reflexed, more or less cylindrical, margin; hinge transverse, linear; beak imperforate; one valve convex, the other flat or concave externally." He also adds:—"His [Martin's] Conch. *Anomites productus* is a good type of the Genus, therefore, as the name *Anomites* must be laid aside, I have adopted his specific name as the Generic one, the character it expresses being also peculiar." Sowerby (*op. cit.* p. 158) renamed *Anomites productus* of Martin *Productus martini*, and describes it in 1821 (Min. Conch. iv. p. 15). Since the species *Anomites productus* (=*Productus martini*) was considered by Sowerby to be typical of his genus, it is in strict accordance with the Rules of Zoological Nomenclature to regard it as the genotype of *Productus*.

Confusion arose as Sowerby figured more than one species as *Productus martini*, and only one of these specimens is identical with *Anomites productus*, Martin. Following de Koninck's and Davidson's lead the species *Productus martini* was regarded as either identical with or a variety of *Productus semireticulatus* (Martin), itself an ill-defined species. In consequence of this, Dall (1877, Bull. U.S. Nat. Mus. viii. p. 58) quoted *Productus martini* Sowerby = *Anomites semireticulatus* (Martin) + *A. productus*, Martin, as the genotype of *Productus*; while Hall (1893, 'Palæontology New York,' viii. p. 325) quoted *P. martini*, Sowerby = *Anomites productus*, Martin = *A. semireticulatus*, Martin = *Productus semireticulatus* as the genotype. Later (1894, Eleventh Annual Report State Geol. p. 297) Hall and Clarke reduced this quotation of the genotype simply to *Productus semireticulatus*.

Productus semireticulatus was, therefore, regarded as the type of the genus *Productus* until I. Thomas (1914, Mem. Geol. Surv. Gt. Brit. Palæont. i. pt. 4, p. 258) quoted *P. productus* as the genotype. This was adopted by Chao in 1927 (Pal. Sinica, B. v. fasc. 2, p. 26) and by me in 1928 (Mem. Geol. Surv. Gt. Brit. Palæontology, iii. pt. 1, p. 35), when the species *P. productus* and *P. semireticulatus* were finally disentangled.

Investigation of the species *P. productus* (= *P. martini*, pars) has shown that it differs in internal structure from *P. semireticulatus* in having an extra shelly plate or diaphragm, which is developed round the anterior end of the visceral disk of the brachial valve and extends between the trails of the two valves, usually at right angles to them.

A similar shelly plate was found by Dr. Girty in the North American species, *P. elegans*, Norwood & Pratten, and this species became the type of his genus *Diaphragmus*. Since the two genera *Productus* and *Diaphragmus* are characterised by a similar internal structure, *Diaphragmus* must be regarded as a synonym of *Productus*.

Productus thus becomes limited to a small group of species, including *P. productus* (Martin), *P. concinnus*, J. Sow., *P. carbonarius*, de Koninck, *P. redesdalensis*, Muir-Wood, *P. garwoodi*, Muir-Wood, etc. A new name is required for *Productus semireticulatus* and allied species, and also for such forms as *P. longispinus* and *P. lobatus*, all of which are at present grouped under the generic name *Productus*. The name *Dictyoclostus*, gen. nov., is therefore proposed for the *semireticulatus* group with *P. semireticulatus* as genotype, and *Eomarginifera*, gen. nov., is proposed for the *longispinus* group with *P. longispinus* as genotype.

Subfamily *Productinæ*, Waagen.

Productus, J. Sowerby, 1814 ('Mineral Conchology,' vol. i. p. 153), *emend.* H. M. Muir-Wood.

Genotype. *Anomites productus*, W. Martin (=*P. martini*, J. Sowerby, pars).

Syn. *Diaphragmus*, Girty (1910, Ann. N.Y. Acad. Sci. xx. pt. 2, no. 3, pp. 217, 218).

Diagnosis.—Shell elongate, both valves geniculate; hinge narrow; pedicle valve with long spreading trail. Flanks steep and posteriorly flattened. Shell costate in all growth-stages, costæ numerous, flexuous. Ribs few, seldom prominent. Spines set in rows on ears and cardinal slopes and scattered on trail. Teeth, dental sockets, and delthyrium absent. Marginal ridges narrow, short. A thin shelly plate or diaphragm developed round anterior margin of visceral disk of brachial valve, extending across space between trails of the two valves.

Species.—*Productus carbonarius*, de Kon., *P. concinnus*, J. Sow., ? *P. furcatus*, Muir-Wood *, *P. garwoodi*, Muir-Wood *, *P. elegans*, Norwood & Pratten, *P. productus* (W. Martin), *P. productus*, var. *hispidus*, Muir-Wood, *P. redesdalensis*, Muir-Wood.

Range.—*Syringothyris* zone to Upper Carboniferous.

Remarks.—This genus has not been found below the C. zone and the geologically earliest described species is *P. garwoodi*, which occurs in the C_1–S_2–D_1 sub-zones of Westmorland. This species, which was apparently developed from *P. rotundus*, Garwood, was probably the ancestor of *P. redesdalensis*, which occurs in the D_1–D_2 sub-zones of N. England and of Scotland. *P. redesdalensis* probably gave rise to *P. carbonarius*, which ranges from D_2 sub-zone up to the Upper Carboniferous. The interior of *P. furcatus* is at present unknown, and this species is doubtfully referred to the genus *Productus*. *P. concinnus* and *P. productus* were probably derived from a form resembling *P. furcatus*.

The distinguishing character of *Productus* is the diaphragm which extends across the narrow space between the trails of the two valves and closes the entrance to the visceral cavity. The diaphragm must therefore have been either porous or movable, in order to admit the passage of water into the shell.

---

* Ref. Muir-Wood, Mem. Geol. Surv. Gt. Brit. Palæont. i. pt. 4 (1928).

DICTYOCLOSTUS, gen. nov.

Genotype. *Anomites semireticulatus*, W. Martin (in part.), Petrificata Derbiensia, p. 7, pl. xxxii. figs. 1, 2, pl. xxxiii. fig. 4 (Wigan, 1809).
Syn. *Productus*, J. Sowerby (in part.).

Diagnosis.—Shell elongate or quadrate in outline. Hinge moderately wide; pedicle valve evenly convex or produced into a short curved trail, brachial valve concave or geniculate. Costate in all growth-stages, costæ often prominent, bearing numerous spine-bases. Spines also in rows on ears and cardinal slopes. Ribs on visceral disk numerous and forming net-like ornament by enlargement at point of intersection with costæ. Diaphragm absent. Marginal ridges prominent, extending along hinge. Hinge-teeth, sockets, and cardinal area not developed.

Species.—*Productus antiquatus*, J. Sow., *P. bristolensis*, Muir-Wood, *P. costatus*, J. de C. Sow., ? *P. flexistrius*, M'Coy, *P. griffithianus*, de Kon., *P. hindi*, Muir-Wood, and var. *wettonensis*, Muir-Wood, *P. howratensis*, Muir-Wood, *P. insculptus*, Muir-Wood, *P. kilbridensis*, Muir-Wood, *P. multispiniferus*, Muir-Wood, *P. muricatus*, Phill., *P. pinguis*, Muir-Wood, *P. projectus*, Muir-Wood, *P. pugilis*, Phill., and mut. *senilis*, Muir-Wood, *P. rotundus*, Garwood, *P. scoticus*, J. Sow., *P. semireticulatus* (Mart.), *P. sulcatus*, J. Sow., *P. teres*, Muir-Wood, *P. vaughani*, Muir-Wood.

Range.—*Zaphrentis*-zone to Permian.

Remarks.—This genus ranges throughout the British Lower Carboniferous and also occurs abundantly in the marine Upper Carboniferous of Europe and North America, as well as in the Permian.

Dictyoclostus is distinguished from *Productus* by the absence of a diaphragm, by its wider hinge, less spreading trail, more prominent and less flexuous costæ.

EOMARGINIFERA, gen. nov.

Genotype. *Productus longispinus*, J. Sowerby, Mineral Conchology, vol. i. 1814, p. 154, pl. lxviii. fig. 1.
Syn. *Productus*, J. Sowerby (in part.).

Diagnosis.—Shell small, quadrate or elongate in outline. Pedicle valve evenly convex or slightly geniculate, with cincture often separating visceral disk from trail, brachial valve concave or geniculate. Costate in all growth-stages, costæ usually fine. Ribs slightly enlarged at point of intersection with costæ. Spines few, not increasing in number in senile stage, six spines symmetrically developed. Exterior of brachial valve with lamellose thickening round anterior and lateral margins. Interior of brachial valve with thickened shelly ridge, bearing slight crenulations, extending from cardinal process round lateral margins.

Species.—*Productus derbiensis*, Muir-Wood, *P. lobatus*, J. Sow., and var. *flexus*, var. *laqueatus*, Muir-Wood, *P. longispinus*, J. Sow., *P. minutus*, Muir-Wood, *P. præcursor*, Muir-Wood, *P. pseudoplicatilis*, Muir-Wood, *P. setosus*, Phill., *P. tissingtonensis*, Sibly, *P. triquetrus*, Muir-Wood.

Range. — Lower Carboniferous, ? C zone to Upper Carboniferous.

Remarks.—This genus is distinguished from *Productus* by the absence of a diaphragm. The symmetrical arrangement of six spines—one on each cardinal extremity, two on the front of the shell below the visceral disk, and one on the posterior part of each flank—distinguishes it from both *Productus* and *Dictyoclostus*. *Eomarginifera* is distinguished from *Marginifera* by the less-marked marginal ridges in the brachial valve and the absence of these ridges in the pedicle valve, also by the lack of crenulations on the exterior of the marginal ridges of *Eomarginifera*. The ornament and arrangement of the spines of *Eomarginifera* are also distinct from those of *Marginifera*. The latter genus is confined to the Upper Carboniferous and Permian.

CLASSIFICATION OF THE *PRODUCTINÆ*.

A considerable amount of overlapping is shown in the researches of Chao, Fredericks, Sarytcheva, and Whitehouse on the subject of the classification of the Productinæ and the following pairs of genera are synonymous. It is unfortunate that Fredericks' genera are described in Russian, with only a short *résumé* in English, and that many of his genera are vaguely described:—

Sowerbina, Fredericks, 1928 (Bull. Com. Géol. Leningrad, xlvi. 7, p. 789): genotype, *P. timanicus*, Stuckenberg = *Horridonia*, Chao, 1927 (Pal. Sinica, B. v. fasc. 2, pt. 1, p. 24): genotype, *P. horridus*, J. de C. Sow. (includes also *P. timanicus*).

Ruthenia, Fredericks, 1928 (*loc. cit.* p. 789): genotype, *P. irginæ*, Stuckenberg (includes also *P. humboldti*, d'Orb., and *P. purdoni*, Dav., etc.) = *Waagenoconcha*, Chao, 1927 (*loc. cit.* p. 85): genotype, *P. humboldti*, d'Orb. (includes also *P. irginæ* and *P. purdoni*).

Cora, Fredericks, 1928 (*loc. cit.* p. 790): genotype, *P. cora*, d'Orbigny [also *Euproductus*, Whitehouse, 1928, nom. nud. (Rept. Aust. Ass. Adv. Sci. xviii. p. 281)]: genotype, *P. cora*, d'Orb. = *Linoproductus*, Chao, 1927 (*loc. cit.* p. 128): genotype, *P. cora*, d'Orb.

Cancrinella, Fredericks, 1928 (*loc. cit.* p. 791): genotype, *P. cancrini*, De Vern., ? = *Linoproductus*, Chao, 1927.

Gigantella, Sarytcheva, 1928 (Mem. Geol. Sci. Res. Inst. Moscow, Geology, p. 13): genotype, *P. giganteus* (Martin) (includes also *P. edelburgensis*, Phill., and *P. latissimus*, J. Sow.) = *Kansuella*, Chao, 1928, pars (Pal. Sinica, B. v. fasc. 3, pt. 2, p. 67): genotype, *K. kansuensis*, Chao (includes also *P. giganteus* and *P. edelburgensis*).

Key to the Classification of the British Productinæ.

A. SHELL COSTATE IN ALL GROWTH-STAGES.

1. Shell ornamented by ribs and costæ on the visceral disk and anteriorly by costæ only. Costæ bifurcating, intercalations rare.
   - (*a*) With diaphragm .... *Productus*, J. Sowerby, 1814, emend. Muir-Wood, 1929 (see p. 102).
   - (*b*) Without diaphragm .... *Dictyoclostus*, Muir-Wood, 1929 (see p. 103).
   - (*c*) Marginal ridge in interior of brachial valve. Shell small, with six spines symmetrically arranged on pedicle valve .... *Eomarginifera*, Muir-Wood, 1929 (see p. 103).
2. Shell costate and ribbed on visceral disk, costate on trail, both valves geniculate. Cardinal area in pedicle valve with delthyrium closed by deltidium ...... *Sinuatella*, Muir-Wood, 1928.
   Genotype: *P. sinuatus*, de Kon.
3. Shell convex (not geniculate), ornamented by costæ and well-marked concentric growth-lines .... *Thomasia*, Fredericks, 1928.
   Genotype: *P. margaritaceus*, Phill.
4. Shell ornamented by fine costæ and numerous intercalations, usually with broad wrinkles on lateral slopes.
   - (*a*) Shell regular, quadrate, pedicle valve highly convex or geniculate .... *Linoproductus*, Chao, 1927.
     Genotype: *P. cora*, d'Orbigny; also *P. corrugatus*, M'Coy, *P. hemisphericus*, J. Sow., *P. koninckianus*, de Vern., *P. undatus*, Defrance.
   - (*b*) Shell irregular or elongate-triangular, tapering to umbo, pedicle valve slightly convex .... *Striatifera*, Chao, 1927.
     Genotype: *P. striatus* (Fischer de Waldheim).
   - (*c*) Pedicle valve cylindrical, brachial valve operculiform .... *Proboscidella*, Oehlert, 1887.
     Genotype: *P. proboscideus* de Vern.; also *P. ermineus*, de Kon.

5. Shell large, massive, hinge long. Costæ fine, irregular. Ribs developed posteriorly.
   (*a*) Cardinal area rarely developed on pedicle valve. .... *Gigantella*, Sarytcheva, [1928.
   Genotype: *P. giganteus* (Martin); also *P. latissimus*, J. Sow., *P. maximus*, M'Coy, *P. edelburgensis*, Phill.
   (*b*) Cardinal area developed in both valves, delthyrium closed by deltidium in pedicle valve .... *Kansuella*, Chao, 1928, emend. H. Muir-Wood, 1929.
   Genotype: *K. kansuensis*, Chao. Probably includes certain undescribed British species.

B. SHELL SPINOSE IN ALL GROWTH-STAGES.

6. Shell ornamented by numerous scattered spine-bases which are anteriorly elongated. Ribs faintly developed on cardinal slopes .... *Krotovia*, Fredericks, [1928.
   Genotype: *P. spinulosus* (Martin); also *P. aculeatus* (Martin).
7. Shell ornamented by elongated spine-bases and concentric ribs.................... *Pustula*, I. Thomas, [1914.
   Genotype: *Productus pustulosus*, Phill.; also *Pustula distorta*, Thomas, *P. interrupta*, Thomas, *P. magnituberculata*, Thomas, *P. nodosa*, Thomas, *Pr. ovalis*, Phill., *P. pilosa*, Thomas, *Pr. pyxidiformis*, de Kon., *Pr. rugatus*, Phill., *P. subpustulosa*, Thomas, *P. tenuipustulosa*, Thomas.
8. Shell ornamented by broad concentric bands bearing rows of spine-bases .... *Echinoconchus*, Weller, [1914.
   Genotype: *Productus punctatus* (Martin); also *P. elegans*, M'Coy, *Pustula subelegans*, Thomas, *P. venusta*, Thomas, *P. defensa*, Thomas, *P. exquisita*, Thomas, *P. eximia*, Thomas.
9. Shell ornamented by concentric bands bearing one row of spine-bases. Brachial impressions spoon-shaped .... *Overtonia*, Thomas, [1914.
   Genotype: *P. fimbriatus*, J. de C. Sow.

C. SHELL SPINOSE AND COSTATE.

10. Shell ornamented by spines posteriorly and costæ anteriorly .... *Avonia*, Thomas, emend. [Muir-Wood, 1928.
    Genotype: *P. youngianus*, Dav.; also *P. bassus*, Vaughan, *P. davidsoni*, Jaross, *P. keyserlingianus*, de Kon.

D. SHELL COSTATE, RIBBED, AND SPINOSE.

11. Shell ornamented posteriorly by ribs and by costæ bearing elongated spine-bases, and anteriorly by flattened bands bearing

rows of spine-bases. Median septum posteriorly bifurcating .... *Buxtonia*, Thomas, 1914, emend. Muir-Wood, 1928.
Genotype: *P. scabriculus* (Martin), also *P. scabriculo-costatus*, Vaughan.

E. Shell ribbed.

12. Shell ornamented by prominent concentric ribs. Anterior margin surrounded by ribbed rim projecting at right angles to shell .... *Thomasella*, Fredericks, [1928.
    Genotype: *P. wrighti*, Dav.
13. Shell ornamented by concentric ribs, and attached by cementation or by spines along hinge of pedicle valve .... *Etheridgina*, Oehlert, [1887.
    Genotype: *P. complectens*, Etheridge.
14. Shell ornamented by ribs and large scattered spines .... *Plicatifera*, Chao, 1927.
    Genotype: *P. plicatilis*, J. de C. Sow.; also *P mesolobus*, Phill., ? *P. carringtonianus*, Dav.

F. Shell smooth.

15. Shell ornamented by large spines and growth-lines, and rarely by faint traces of costation .... *Horridonia*, Chao, 1927.
    Genotype: *P. horridus*, J. de C. Sow.

The precise range of many of these genera is uncertain. *Horridonia* is apparently limited to the Permian. *Thomasia* and *Thomasella* occur in the Upper *Dibunophyllum*-zone, but may range upwards. *Kansuella* is possibly confined to the Lower Carboniferous, and occurs in the *Dibunophyllum*-zone. *Gigantella* and *Striatifera* are not known below the *Seminula*-zone, and are especially characteristic of the Upper *Dibunophyllum*-zone, but they extend up into the Upper Carboniferous or even into the Permian. *Productus*, *Linoproductus*, *Plicatifera*, and *Eomarginifera* were probably evolved in Upper *Zaphrentis* or Lower *Syringothyris* times, but became more abundant in D_2. *Linoproductus* and *Productus* extend up to the Upper Carboniferous. *Buxtonia*, *Pustula*, *Echinoconchus*, *Avonia*, and *Dictyoclostus* appear in the *Cleistopora*-zone or early *Zaphrentis* times, and range throughout the Carboniferous.

VIII.—*Descriptions and Records of Bees.*—CXXI.

By T. D. A. Cockerell, University of Colorado.

Andrena kuznetzovi, sp. n.

♀ (type).—Length 13·7 to 14·7 mm.

Head, thorax, and legs black; abdomen shining green, the depressed parts of the tergites bluish green, the first tergite purplish black except apically, the second suffused with purplish black across the middle, the third to fifth with the elevated part yellowish green; hair of head and thorax long and thin, rather dull white, black at apex of clypeus, on vertex, across middle of thorax, between wings (but thin), and on legs, but anterior femora with long white hair behind, middle femora with some white hair above, hind femora with a white fringe in front, and the large curled floccus pure white; abdomen without bands, caudal fimbria greyish black, with long white hairs overlapping and at sides; facial quadrangle broader than long, very long white hair at sides of face; malar space linear, but evident; mandibles ordinary; process of labrum very broad, rounded; clypeus finely and densely rugoso-punctate, but glistening, with a delicate median raised line; front striate; flagellum dusky reddish beneath, except at base; third antennal joint long, exceeding next two together; facial foveæ dark chocolate-brown, moderately broad, running close to orbits, and ending much below level of antennæ; mesothorax dull and minutely granular, except the posterior middle, which is shining and sparsely punctured; scutellum bigibbous, the elevations shining, the surface much more closely punctured than posterior part of mesothorax, but on each side a little space with few punctures; area of metathorax triangular, poorly defined, minutely rugulose, with feeble irregular plications (hardly evident under lens) at base; mesopleura dullish; tegulæ black. Wings long, hyaline, the upper portion and apex suffused with pale brown; basal nervure meeting nervulus; second cubital cell very broad, receiving recurrent nervure slightly or considerably beyond middle; third cubital shorter than usual; spurs black; second tergite depressed in middle about a third. Surface of abdomen under microscope minutely tessellate, with sparse, very minute, piliferous punctures; under a lens the abdomen appears impunctate.

♂.—Length about 12 mm.

With the usual sexual differences; face very broad; mandibles long but stout, with an inner tooth; face with long pure white hair, but much black at sides; flagellum long, dark brown beneath; third antennal joint not as long as next two together, the fifth being unusually long; thorax with long white hair, black on disc of scutellum; stigma narrow, red with a dark margin; abdomen shining steel-blue.

Tashkent, Usbekistan, March 25, 1926; many females and two males (*N. Kuznetzov*).

A fine species of the group of *A. cineraria*, L., in the Central Asian fauna to be compared with *A. metallescens*, Ckll., from Tamerlan-Kuporjuk, which has the caudal fimbria fulvous, and with *A. peregrina* (Smith), from Yangihissar, which has the wings with a deep fuliginous cloud and the female abdomen dark purple.

There is some general resemblance to *A. ferghanica*, Mor., which is rather large, with the hair on the thorax grey. The male has the abdomen much more polished than in *A. cineraria* (L.).

Andrena kuznetzovi, form *micrander*, nov.

On the same day and also on March 21 Prof. Kuznetzov took numerous males, 9 to 9·5 mm. long. I set these aside as a different species, but they have no valid characters, and I find the genitalia of the large and small males to be exactly alike. It is thus evident that the male of this species is sharply dimorphic as to size.

Andrena brevipalpis, sp. n.

♀.—Length about or hardly 10 mm., anterior wing 7.

Black, rather slender; head and thorax with erect hair, fulvous dorsally, pale greyish on face, cheeks, and pleura; facial quadrangle about square; malar space linear; mandibles ordinary; process of labrum broadly truncate; clypeus thinly hairy, shining, but with a minutely tessellate surface, with widely scattered large punctures, the middle line impunctate but not elevated or polished; front striate; third antennal joint slightly longer than next two together; flagellum ferruginous beneath except at base; facial foveæ moderately broad, pale clear ochreous, close to orbits, extending below level of antennæ; mesothorax dullish, but shining on disc, the surface minutely tessellated and rather sparsely (hardly noticeably under lens) punctured; scutellum shining; area of metathorax poorly defined, entirely dull and rugulose, without plicæ; lower part of mesopleura somewhat shining; tegulæ rufo-fulvous. Wings hyaline, slightly dusky; stigma not very large, pale fulvous with dark margin, nervures pale fuscous; basal nervure falling short of nervulus; second cubital cell rather small, a little higher than long, receiving recurrent nervure at about the end of the third fifth. Legs black, with pale hair, light rufo-fulvous on inner side of tarsi; tibial scopa ample and rather loose, very pale fulvous, the hairs on outer side simple; claws bifid; scopa of hind femora very long and white. Abdomen moderately shining, dull in some lights, so finely punctured as to appear practically impunctate under a lens; second tergite in middle depressed less than half but more than a third; tergites 2 to 4 with narrow, dense, very pale ochreous hair-bands, broadly interrupted on second; caudal fimbria dark brown.

Boulder, Colorado; one ♀ captured on the window of my office at the University of Colorado, June 26, 1929.

It has almost exactly the aspect of *Iomelissa violæ*, Rob., and looked at from behind could be supposed identical; but the face is much narrower and the palpi are short, whereas in *Iomelissa* they are much elongated. In Viereck's Connecticut table it runs to *A. novæangliæ*, Vier., but it is not that.

Andrena basifusca, sp. n.

♀.—Length about 12 mm.

Robust; head, thorax, and legs black, abdomen dark purple-blue; first tergite mainly black, with apical margin blue; second shining black, with the depressed part brilliant purple; third and fourth purple, blue along the margins of the depression; fifth blue, with apical fimbria black; sides of face with long white hair, vertex and cheeks with black hair; thorax anteriorly and posteriorly with white hair, but black between the wings; sides of thorax with black hair, but white on tubercles, and upper part of mesopleura with some long white hairs. Abdomen bare. Legs with black hair, long white hairs on anterior femora behind, and basal floccus of hind legs white; facial quadrangle broader than long; malar space linear; clypeus glistening but not polished, closely punctured, with a strong median ridge; flagellum very obscurely brownish beneath; third antennal joint longer than the next two together; foveæ not very broad, dark brown, separated from eye by a wide shining band; mesothorax and scutellum densely punctured but glistening; mesothorax polished posteriorly, but scutellum hardly so anywhere; area of metathorax triangular, rugulose, with feeble plicæ at base; tegulæ black, a little reddish posteriorly. Anterior wings deep fuliginous, violaceous, the brown colour extending to base; basal nervure meeting nervulus; second cubital cell very broad, receiving recurrent nervure beyond middle; stigma small and black; second tergite in middle depressed more than a third but less than half. Abdomen shining, without evident punctures.

Ak-Tasch Mountains, Usbekistan, June 19, 1926 (*N. Kuznetzov*).

Very like *A. peregrina* (Smith), but easily distinguished by the wings not being hyaline at base.

Also resembles *A. hemicyanea*, Ckll., but the wings not longitudinally bicoloured, and clypeus different. It may also be compared with *A. fumipennis*, Schm., but that has a quite different clypeus and wings not so dark.

Andrena zachroa, sp. n.

♀.—Length about 11·2 mm.

Head and thorax black, with stiff very rich ferruginous-red hair, dense on sides of face and about antennæ, on sides of mesothorax and scutellum, and on postscutellum, but very sparse on clypeus and discs of mesothorax and scutellum; malar space linear; mandibles very faintly reddened about middle; labrum black, the process truncate; antennæ black, third joint nearly as long as next two combined; clypeus flattened, dull, minutely and densely punctured, with a delicate median raised line; facial foveæ broad, but very inconspicuous, largely overlapped by the spreading red hair; cheeks shining; mesothorax dull, slightly shining, very finely and closely punctured, microscopically tessellate between the punctures; posteriorly the mesothorax is more shining, and the scutellum is shining; area of metathorax entirely dull and granular, without plicæ, and defined only by absence of hair; mesopleura dull; tegulæ shining dark red. Wings strongly reddened; stigma moderate, dull ferruginous, with darker margin; nervures fuscous; basal nervure going basad of nervulus; second cubital cell about square, receiving recurrent nervure a little beyond middle; third cubital long. Legs black, with anterior tibiæ apically, and their tarsi, middle femora apically, and their tibiæ and tarsi, and hind femora, tibiæ, and tarsi all red; scopa of hind legs bright red; spurs red; middle basitarsi broad. Abdomen flattish, mostly bare, moderately shining, reddish black, with the first tergite, sides of second, and transverse suffusion on third and fourth rather dark red; a large black spot at each extreme side of second; apices of segments 2 to 4 with broad, dense, very bright orange-fulvous hair-bands, very widely interrupted on 2, narrowly on 3, entire on 4; apical tuft red; venter black, with red hair-bands.

Tunis; no other data available.

One of the most beautiful species of the genus. It resembles *A. cirtana*, Lucas, which I saw in Mr. Morice's collection, and noted; very handsome shining red abdomen, first tergite black with red hind margin; hair of head and thorax entirely bright red. There is also a strong resemblance to *A. russula*, Lep., judging from the description, but that has the abdomen black, with the band on the fourth tergite interrupted. The length is given as 4½ lines, which appears too small; but *A. oraniensis*, Lep., is said to be 4 lines, and it is actually over 12 mm. long. It is possible that the present insect is a rufescent variety of *A. russula.*

Andrena melandura, Cockerell, 1922.

Andrena æmula, Alfken, 1926, is a synonym.

Andrena hemicyanea, sp. n.

♀.—Length about 13 mm., anterior wing 10·5.

Robust; head, thorax, and legs black; abdomen dorsally deep blue, shining, but the venter brownish black; head broad, facial quadrangle nearly square; mandibles black, malar space linear; sides of face with long, outstanding, very conspicuous white hair; occiput and upper part of cheeks with long white hair; lower part of cheeks, sides of vertex, and clypeus with black hair, on clypeus thin and not conspicuous; clypeus very densely and strongly punctured, glistening between the punctures, and with a strong shining median keel; process of labrum shining, broadly rounded, with sloping sides; facial foveæ dark chocolate-brown, moderately broad, going below level of antennæ, with only a linear separation from orbits; antennæ black, third joint very long, about equal to next two combined; thorax practically hairless above, tubercles conspicuously tufted with white hair; sides of metathorax with much white hair, forming a scopa; pleura very coarsely rugoso-punctate, with thin black hair; mesothorax shining, with scattered distinct punctures; scutellum similarly sculptured, the punctures very sparse on disc; postscutellum coarsely punctured, not hairy; area of metathorax large, dull, with coarse wrinkles, and defined by a rounded line (not at all squared off behind); tegulæ black. Anterior wings with the upper half deep fuliginous, violaceous, the lower portion and a space just beyond third discoidal cell hyaline; stigma narrow, reddish, with dark margin; nervures dark fuscous; basal nervure going well basad of nervulus; second cubital cell broad, receiving recurrent nervure a little beyond middle; third cubital about as broad on marginal as second. Legs with mainly black hair, but much white on anterior femora behind, on hind femora beneath, and scopa of hind tibiæ outwardly white; hair on inner side of hind basitarsi purplish black; spurs black. Abdomen broad, shining, practically hairless above, but with a dense black caudal tuft, the sides of fifth tergite with much white hair and of fourth with white tufts; surface of tergites polished, feebly punctured; second tergite in middle depressed less, but not much less, than one-half.

Tunis; no other data available.

Closely related to *A. agilissima* (Scopoli), for which it might be taken, but a little smaller, the raised part of second tergite less closely and evenly punctured; area of metathorax shorter and broader, more semicircular; mesothorax more shining and less closely punctured; third cubital cell more produced apically. *A. asperrima*, Pérez, departs from the *A. agilissima* type in the opposite direction.

Andrena kengracensis, sp. n.

♀.—Length 11·2 mm.

I had referred this to *A. flavipes* (Panzer), which is recorded from this region, and no doubt it has been so regarded. In the Tashkent Museum I saw a specimen from Tashkent labelled "*A. fulvicrus*, Kirby (=*flavipes*)," but whether it was *A. kengracensis* I cannot now say. On comparison with *A. flavipes* from Gray, France (*André*), the new species differs by the dull white hair of under surface of thorax and sides of face, which should refer it to *A. gravida*, Imh.; but it differs from *gravida* (from Hastings, *Sladen*) by the shorter hind basitarsi, with the hair on the inner side dark chocolate instead of lively pale reddish. The third antennal joint is much longer than the next two together, the fourth being short and transverse. In *A. gravida* the fourth joint is longer. The three abdominal bands of *A. kengracensis* are pure white, instead of having a pale ochreous tint as in *A. flavipes.* Thus, while the insect runs to *A. gravida* in the tables, it is, on the whole, a closer relative of *A. flavipes,* perhaps best regarded as a subspecies. The type-locality is Kengrak hills, 26–28 kilometres north of Tashkent, Usbekistan, in a stony desert, May 16, 1926, 4 ♀ (*N. Kuznetzov*). Also one from Ak-Tasch mountains, about 1250–1600 metres above sea-level, June 22, 1926 (*Kuznetzov*).

Andrena (*Ptilandrena*) *pronitens*, sp. n.

♀.—Length about 8 mm.

Black, with the small joints of the tarsi reddish; hair of head and thorax erect and abundant, pale ferruginous dorsally, long and bright on scutellum; hair of face (very thin), cheeks, and underside of thorax dull whitish; malar space very short; mandibles ordinary, very faintly rufescent subapically; process of labrum elevated, broadly truncate; clypeus strongly convex, highly polished and impunctate on disc, dull at extreme sides; front striate; facial quadrangle broader than long; antennæ black, third joint not very long, but as long as next two together, or nearly so; facial foveæ rather broad, pale brown, very conspicuous, ending below at level of antennæ, with only a linear separation from orbits; mesothorax dull, scutellum shining, mesopleura dull; area of metathorax large, triangular, dull, with very short plicæ (between which the surface is somewhat shining) at extreme base; tegulæ dark brown. Wings reddish hyaline, apically greyish; stigma large, clear ferruginous, approaching orange; nervures pale ferruginous; basal nervure falling short of nervulus; second cubital cell narrow, receiving recurrent nervure at beginning of its last third. Legs with pale fulvous hair, the tibial scopa very pale, not dense, on outer side with strongly plumose (pectinate) hairs, the branches not numerous. Abdomen rather broad, dullish, appearing impunctate, the microscope showing a minutely tessellate surface with excessively minute scattered punctures; second tergite in middle depressed less than a third; tergites 2 to 4 with narrow greyish-white hair-bands, very thin in middle of second; apex with very pale grey hair.

Geneva Park, Boulder, Colorado, May 14, 1929 (*Hugo Rodeck*).

Resembles *A. beckeri*, Ckll., but easily distinguished by the clypeus. There is, perhaps, little real affinity, as in *A. beckeri* the hairs on outer side of hind tibiæ are simple.

Another species with shining clypeus, taken at Boulder, is *A. flavoclypeata*, Smith. Robertson places this in his genus *Opandrena*, but actually the hair on outer side of hind tibia in the female is plumose.

Mr. Rodeck also took at Boulder *A. nasoni hartfordensis* (Ckll.), new to Colorado.

At Rifle, Colorado, Mr. S. A. Rohwer took *A. sapellonis*, Ckll., also new to Colorado.

Andrena azalearum, sp. n.

♀.—Length about 12 mm.

Not unusually robust; black, including mandibles, antennæ, tegulæ, and legs; hair of head and thorax white, but black on vertex, sides of face above, posterior part of mesothorax, and scutellum; legs with mainly white hair, pale ferruginous on inner side of tarsi, scopa of hind tibiæ bicoloured, white in front, black behind; abdomen dorsally bare, a little pale hair at sides, caudal fimbria black, ventral segments fringed with long glistening white hairs; facial quadrangle broader than long; malar space linear but evident; mandibles ordinary; clypeus convex, shining, distinctly and rather closely punctured, with no median ridge; process of labrum narrowly truncate; third antennal joint not specially long, but about equal to next two together; facial foveæ broad, entirely dark, separated from eye by a rather wide band, which, however, is not shining; mesothorax dull anteriorly, posteriorly polished, with scattered rather small punctures; scutellum shining; area of metathorax poorly defined, triangular, entirely dull, weakly plicatulate at base; mesopleura moderately glistening. Wings long, brownish hyaline, more dusky at apex; stigma moderate, black; nervures dark fuscous; basal nervure meeting nervulus; second cubital cell broad, receiving recurrent nervure about middle; spurs light reddish. Abdomen shining, very finely but distinctly punctured; second tergite in middle depressed much more than a third but less than a half.

Japan, near Tokyo; on *Azalea*, May 13, 1929 (*Dorsett and Morse*). U.S. National Museum.

A very distinct species, which runs out in my table of Japanese *Andrena* (Ann. & Mag. Nat. Hist., Feb. 1913) next to *A. watasei*, Ckll.

Nomia semiaurea thor, subsp. n.

♀.—Tegument of legs entirely black.

♂.—Described in "Bees.—CXVII.," p. 137.

Thursday Island, March 15 (*Cockerell*).

IX.—*Some Remarks on* Dictyoconoides, *Nuttall* (=Conulites, *Carter* =Rotalia, *Lamarck*). By C. van Rijsinge, The Hague, Holland.

[Plates V. & VI.]

In 1861 H. J. Carter created for some conical fossil Foraminifera the new genus *Conulites*, of which he described one species: *Conulites cooki* (H. J. Carter, "On Fossil Foraminifera of Scinde," Ann. & Mag. Nat. Hist. ser. 3, vol. viii. 1861, pp. 331–332, and pp. 457–458, pl. xv. figs. 7 *a–g*).

The next year W. B. Carpenter, having examined the new-described forms, came to the conclusion that he could best unite this genus and *Orbitolina*, d'Orbigny, with the genus *Patellina*, Williamson, and hence in his 'Introduction' the fossil appeared under the name *Patellina cooki* (W. B. Carpenter, W. K. Parker, and T. R. Jones, 'Introduction to the Study of Foraminifera,' 1862, pp. 233–234, text-fig. xxxviii. *a–g*).

In 1905 H. Douvillé and Ch. Schlumberger referred briefly at the end of a publication on *Dictyoconus* and *Lituonella* to the genus *Conulites*, Carter, stating:—"Il résulte en tout cas de ces indications que ce genre appartient aux Perforés" (H. Douvillé and Ch. Schlumberger, "Sur deux foraminifères éocènes," Bull. de la Soc. géol. de France, ser. 4, pt. v. 1905, p. 304).

This is a most important remark, that apparently has been overlooked, as we find the genus *Dictyoconoides* placed by Cushman in his last classification in the family of the Orbitolinidæ, which contains only imperforate forms, with mostly arenaceous tests.

There are not many studies of the subject until the publication of W. L. F. Nuttall in 1925 *; they are of no importance, or maybe I have overlooked them.

The name *Conulites* according to his investigations being preoccupied, he proposes the name *Dictyoconoides*, as externally Carter's *Conulites* is somewhat like *Dictyoconus*.

He states that the fossil, described by Carter as *Conulites*, cannot be arranged in the group of *Patellina*, as Carpenter did, for the following reasons:—

1. There being no segmental arrangement of the chambers.

---

* W. L. F. Nuttall, "Two Species of Eocene Foraminifera from India," Ann. & Mag. Nat. Hist. ser. 9, vol. xvi. 1925, p. 370.

2. The genus *Patellina* not having, in its original description, the internal pillar-structure, which is one of the peculiar characteristics of *Dictyoconoides*.
3. *Patellina* being much smaller than the now-called *Dictyoconoides* *.

The only resemblance is the conical shape, but it is really impossible to consider this as a proof of the relation between these forms, since a conical outline is found also in other Foraminifera and may be regarded as an adaptation to the life-circumstances of the animal.

There are also marked differences between *Dictyoconus* and *Dictyoconoides* :—

1. *Dictyoconus* being arenaceous, while *Dictyoconoides* is calcareous.
2. *Dictyoconus* having a subepidermical reticulate structure.
3. The central part (umbilicus) of *Dictyoconus* being filled up with chambers and not with pillars, as is the case in *Dictyoconoides*.

Thirdly, Nuttall demonstrates the difference between *Dictyoconoides* and *Orbitolina* :—

1. *Orbitolina* being arenaceous.
2. The chamber-arrangement of *Orbitolina* being cyclical and not spiral.

Supposing that the description given by Carter is not complete, Nuttall gives another description of *Dictyoconoides cooki*, from which it may be well to refer to some points.

A remarkable fact is that all the tests examined by Nuttall happened to be microspherical. The septal partitions between the chambers were double, just as is the case in *Nummulites*; they showed canals, whose further extensions, however, could not be traced. Seen on a transverse slide the chambers open at the ventral side towards the umbilicus. These internal openings "represent cells, which are divided by horizontal partitions."

Vertically these "cells" are divided by columns, which radiate first from the apex, later on from the whorl-walls. They show fine longitudinal striations. They do not enlarge near the end. Nuttall states that there is not a trace of a lateral communication between the chambers.

---

* Hofker tells me that he has discovered in *Patellina* the typical inner characteristics of *Rotalia*. Publication of these views will follow soon. As I also, as will be shown, could trace the close relation of *Dictyoconoides* to *Rotalia*, it was after all not so wrong to consider those two genera as a single genus.

H. Douvillé published in 1926: "La Forme conique chez les Foraminifères et le genre *Dictyoconoides*, Nuttall" (Bull. de la Soc. géol. de France, ser. 4, part xxvi. 1926).

In this study Douvillé refers to the conical shape as being a result of the surroundings of the individual, the quantities of food, and a pre-existing deformation of the initial chamber. He also mentions the intercalary spirals, which he supposes are formed when the last chamber before the bifurcation has two apertures instead of one. The columns bear at more or less regular distances apophyses, which correspond with the periods of growth of the organism.

The lacunæ thus remaining between those columns and apophysis must—according to Douvillé—have been filled up with protoplasm and are connected by means of lateral openings with the interior of the chambers in the whorl.

The walls of the test are finely porous, which is—as Douvillé emphatically declares—different from *Dictyoconus* and *Orbitolina*, these genera having an arenaceous test.

The same year (1926) brings also an elaborate study by L. M. Davies: "Remarks on Carter's Genus *Conulites* (=*Dictyoconoides*, Nuttall), with Description of some new Species from the Eocene of North-west India" ('Records of the Geological Survey of India,' vol. lix, part 2, p. 237).

He recalls that Wynne (Mem. Geol. Survey of India, vol. xi. part 2, p. 139) described some Rotalinæ from the Eocene, between which—as he thinks—this *Dictyoconoides* can also be found.

Yet Davies is here referring to *Conulites* and maintains this name in his article for the new species there described. I believe, however, that it is not right to keep the name *Conulites* for these Foraminifera, the name being used too much for other organisms.

So I think it best to replace this name by the name *Dictyoconoides*, Nuttall *.

Now Davies describes *Conulites kohaticus*, and here he states that he could not clearly distinguish the embryonic chamber, and thus was unable to state dimorphism.

He mentions *D. kohaticus*, var. *spintangiensis*, a flatter, somewhat larger, and more heavily built variety, *D. kohaticus*, var. *blanfordi*, a more conical form, *D. vredenburgi*, a rather small form, with relatively large chambers, and *D. tipperi*, a little globular Foraminifer, with enormous chambers.

---

* As I will show later, I consider *Dictyoconoides* to be a typical *Rotalia*. To prevent confusion, I thought it better to retain in this article the name *Dictyoconoides*.

In 1928 appeared a study of H. Douvillé, wherein he suggested that the genus is referable to the same family as *Calcarina* (Séances de la Soc. Géol. de France, Compte rendu sommaire de 2 avril 1928, p. 94).

As I have not been able to obtain this article, I am sorry I am unable to refer its contents.

The study of *Dictyoconoides* had progressed so far when in two letters L. M. Davies questioned J. Hofker about the problem and also sent some material.

Dr. Hofker kindly transferred the material to me, who am at present studying Foraminifera in his laboratory. I wish to express here my special thanks to him for his calling my attention to these interesting fossils, and also for the kind and valuable advice he gave me during the study of *Dictyoconoides*.

To complete my study of the literature I may append here the ideas of L. M. Davies expressed in his letters of 30 April and 24 June of 1928, just mentioned.

Here Davies calls the type rotaliform, but states that there is some conformity with the Nummulites and Orbitoids :—

1. The presence of pillars.
2. Traces of a supra-cortical skin that can be found on the upper surface.
3. The spiral, which may be left- as well as right-handed, this being in his estimation an indication of bilateral symmetrical inclination.

However, there is some difference :—

In Nummulites: there being no marginal cord.

In Orbitoids: the spiral arrangement of the chambers, as they are arranged cyclically in the Orbitoid species.

The septa seem to be perforated at the base and the chambers open in the umbilicus.

In his second letter he refers to the above-mentioned study of H. Douvillé (1928) and sets out the differences from *Calcarina* according to him :—

1. The typical spines of this genus are never found in *Dictyoconoides*.
2. The pores of *Dictyoconoides* are finer than those of *Calcarina* and never coalesce.

3. In *Calcarina* there are never the intercalary spirals which are so common in *Dictyoconoides.*
4. The communication between the chambers of *Dictyoconoides* is formed by one single large perforation.

Dictyoconoides has so far been found only in the Lower and Middle Eocene of North-west India, the Eocene of South Arabia, the Middle Eocene of Northern Somaliland.

Finally, Davies remarks: "I am struck by the apparent bilateral characters of this genus, as well as by its apparent affiliations to *Rotalia.*"

In short, with respect to the relationships of *Dictyoconoides,* we must decide between *Rotalia, Calcarina, Nummulites, Orbitoides,* and *Orbitolina,* these names being already mentioned in literature, or perhaps establish quite another relationship.

It is possible to divide the above-mentioned Foraminifera into two groups. As the Calcarines, Nummulites, and Rotalids are more closely allied, they can be separated from the Orbitolines, which are in no respect related to the first-mentioned three groups, and the Orbitoids, which also are not so closely allied to the first three.

In the most modern work on the classification of Foraminifera (J. A. Cushman, "Foraminifera, their Classification and Economic Use," Cushman Laboratory for Foram. Research, Special Publication No. 1, Sharon, Mass., 1928, p. 178) the family Orbitolinidæ is said to have the following characteristics :—"Test usually conical; early chambers spiral, later ones annular, subdivided into chamberlets, the central portion of the test with irregular chambers; wall finely arenaceous, siliceous, or calcareous; apertures on basal side of the test multiple in higher forms."

As will be shown, there are really great differences between the hitherto-known species of *Dictyoconoides* and the definition of the family Orbitolinidæ just given.

There is no question about the whorl of chambers in later periods of life becoming cyclically arranged, nor can anything be found that indicates a subdivision of the later chambers into chamberlets. Also, it is wrong to suppose the inner structure of the test to be built up by irregular chambers. As Douvillé (H. Douvillé, *l. c.* 1926, p. 25) has already declared, the walls of the test are finely porous, which indeed marks a great difference from the imperforate family of Orbitolines. Nor can it be denied that there are *not* many apertures on the basal side of the test. Probably

Cushman means the openings of the umbilical canal-system at the basal side, when referring to "apertures."

Thus it will be clear that *Dictyoconoides*, having only its systematically unimportant conical shape in common with the Orbitolines, must be removed from this family.

The differences did not remain unobserved by Cushman, who declared in his work cited above (J. A. Cushman, *l.c.* 1928, p. 184):—"*Dictyoconoides* is a very peculiar form, and probably has its affinities with the Rotalidæ or related families, but is left here until more is known of its relationships."

The Orbitoididæ are as yet not a quite logically arranged family, systematically speaking, as Wayland Vaughan points out in Cushman's "Classification" (J. A. Cushman, *l.c.* 1928, p. 335). This definition of the family is as follows:—

"Test thin or inflated, round lenticular, selliform or stellate, with a layer of equatorial chambers, which in the megalospheric generation begins growth from a multilocular embryonic apparatus. Chamber-walls perforate, usually also communication between chambers through openings for the passage of protoplasmatic stolons. *There is no canal-system.*"

As published sections and my own preparations show, there is no question about the growth from a "multilocular embryonic apparatus." Also the chambers are not equatorially arranged. Finally, of great importance is the absence of a canal-system in Orbitoids, as a canal-system is markedly and typically developed in *Dictyoconoides* and places it near the rotaliform Foraminifera. Coming now to Rotaliidæ, Calcarinidæ, and Nummulitidæ, it is perhaps best to give an account of the characteristics, place, and composition of these families.

It is a remarkable fact that, until now, most of the characters used for the limitation of families, genera, and species are taken from the general habitus of the animals. Nor can it be gainsaid, that, so long as, by a deeper study, important differences in internal structure are not known, one has a right to describe the very same forms by the same name, and, on the other hand, forms in shape widely apart by different generic and family names.

However, there can be found many evidences in foraminiferal literature that the outer shape is not a safe guide for the determination of relationships.

So we may perhaps as well, or better, turn our attention to the internal structure of the Foraminifera. As an account of this subject will fully agree with the views of Hofker, I might perhaps refer to his work on the 'Siboga' Foraminifera (J. Hofker, "The Foraminifera of the 'Siboga' Expedition," Monograph iv. of 'Uitkomsten op Zoologisch, Botanisch, Oceanographisch en Geologisch Gebied, verzameld in Nederlandsch Oost Indie,' 1899–1900 aan boord van Hr. Ms. 'Siboga.' Edited by Dr. Max Weber, Leiden 1927, part i.) and his study on the Nummulitidæ (J. Höfker, "De Nummulitidæ," Tijdschrift Nederl. Dierk. Vereeniging, (2) part xx. 1927, p. 3), but as the first may not be so easily obtained and the second is written in a little-known language, it will not be superfluous to set out the contents here.

It is possible to distinguish two groups in the genera which so far have been assigned to the family Rotaliidæ when studying the inner structure: one group possessing a remarkable and typical canal-system and one group lacking it. As far as known now, Rotalia alone shows this system.

The family of the Calcarinidæ also shows this characteristic. There are the genera *Calcarina*, *Baculogypsina*, *Arnaudiella*, and *Patellispira*, which have a typical Rotalid canal-system, and so all the genera of this family may be regarded as a more or less distinct subfamily in the family Rotaliidæ.

To this family now can also be added the subfamily of the Polystomellidæ, generally considered as a part of the Nummulitidæ.

The Nummulitidæ, too, show a canal system that, though it may possess many resemblances to that of the Rotaliidæ, is distinctly different from it.

The canal-system of the Rotalid forms mentioned above consists of a typical spiral canal, running close under the whorl of chambers. From it spring interseptal canals, which may be simple in lower forms, but in the highest development in their turn give off little branches and in the end open with bifurcations at the dorsal suture of the shell (*cf.* the description of *Dictyoconoides kohaticus*). The spiral canal itself continues to run under the chamber-whorl, and finally opens at the umbilical margin of the last chamber. The chambers show a prolongation towards the ventral side, which in *Rotalia polystomelloides* is prolonged into the septal wall and on the other side opens in the spiral canal (J. Hofker, "Foraminifera of the 'Siboga' Expedition," part i. 1927, p. 35, pl. xvi. figs. 2, 4, and 5).

From the spiral canal canals branch off also towards the umbilicus. In *Rotalia polystomelloides* they run straight on to the ventral side and there they open. In *Rotalia schroeteriana* they form an irregular network and also open on the ventral side of the shell in the umbilical region (J. Hofker, *l. c.* 1927, pl. xix. figs. 8 and 9).

This system is also typically shown in the Calcarinidæ and the Polystomellidæ. In the latter the system is double, as there is an umbilicus at both sides of the test.

The family of the Rotaliidæ thus includes the subfamilies Rotaliinæ, Calcarininæ, and Polystomellinæ.

In the Nummulitidæ it is possible to separate a primary and secondary canal-system. The primary canals are formed in *a single* chamber-wall, really as a canal. The secondary canals are formed when two chamber-walls meet, grow together, and some space is left between them. (In this way the Rotalid system is formed.) The primary canal-system is to be found at the marginal side of the chambers. In the first rows it forms a simple canal, but later on by anastomosing the "marginal cord" is formed. From this marginal cord there extend many canals mostly secondarily formed. So there is really a pronounced difference from the Rotalid spiral system, this being formed secondarily at the base of the chambers and extending along the umbilical side.

The Nummulitidæ have an embryonic structure that in the megalospheric forms does not show a so-called "raspberry-structure," like the Planorbulinidæ, which, moreover, do not possess a canal-system.

Thus defined, the true Nummulites are: — *Assilina, Nummulites, Operculina, Heterostegina, Spiroclypeus, Cycloclypeus* (J. Hofker, "De Nummulitidæ," Tijdschr. Nederl. Dierk. Vereen. (2) pt. xx. 1927, p. 3).

DESCRIPTION OF THE MATERIAL.

L. M. Davies kindly sent:—

Dictyoconoides kohaticus, from the uppermost Laki beds of Kohat.

D. kohaticus, from the uppermost Laki beds of Bahadur Khel.

D. kohaticus, var. *spintangiensis*, from Spin Tangi.

D. vredenburgi, from the middle Laki beds near Hindu Bagh.

D. haimei, from the uppermost Ranikot beds at Thal.

For this beautiful material we are greatly indebted to him, and now express to him our best thanks.

According to L. M. Davies the geological succession is as follows :—

Lutetian	Khirthar.
Ypresian	Laki. Uppermost Ranikot.
Landenian	Ranikot.

(L. M. Davies, "Notes on the Correlation of Pinfold's Chharat Series with the Eocene Stages of Sind and Europe," Transact. of the Mining & Geol. Inst. of India, part 3, 1926, p. 195.)

In his letter of 24 June, 1928, Davies evidently regards the uppermost Ranikot as also Landenian, since he places *Dictyoconoides haimei* and other types of the Ranikot and uppermost Ranikot altogether in the Landenian.

It may be remarked that the terms Landenian and Ypresian are not always used, and by E. Haug they are included to the Londinian (E. Haug, 'Traité de Géologie,' part ii. fasc. 3, pp. 1424, 1419). Also Haug does not refer the Londinian to the Eocene (as Davies and others do Landenian and Ypresian), but to the Palæocene.

Dictyoconoides kohaticus, Davies. (Pl. VI. figs. 1–4.)

Conulites kohaticus, Davies (L. M. Davies, "Remarks on Carter's Genus *Conulites* etc.," Rec. Geol. Survey of India, vol. lix. part 2, 1926, p. 240, pl. xvi. figs. 1–4, pl. xvii. figs. 5–5 *c*).

Conulites kohaticus, var. *spintangiensis*, Davies (L. M. Davies, *l. c.* p. 245, pl. xvii. fig. 6).

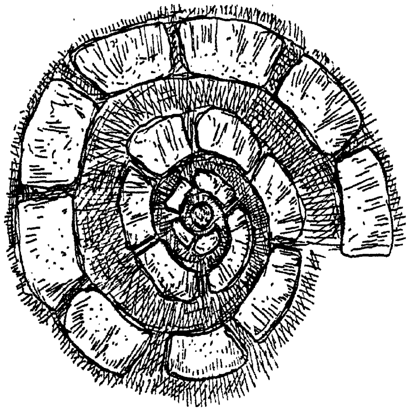
The sample contained three distinctly different types, though it was quite obvious that they must belong to the same species, their only difference being the more or less conical shape and (as will be shown further on) the dimensions of their embryonic chamber.

One type was a rather high conical form, having a basal diameter of about 5 mm. and a conical height of 2 mm. (Pl. VI. figs. 4 *a*, *b*). A slide made through the embryonic apparatus showed a large first chamber (text-fig. 1).

The second type also was rather conically shaped, though much less than the first. The basal diameter was about 7 mm. and the conical height 2 mm. or little less (Pl. VI. figs. 3 *a*, *b*). The slide showed beyond doubt that the form was a megalosphericone (text-fig. 4).

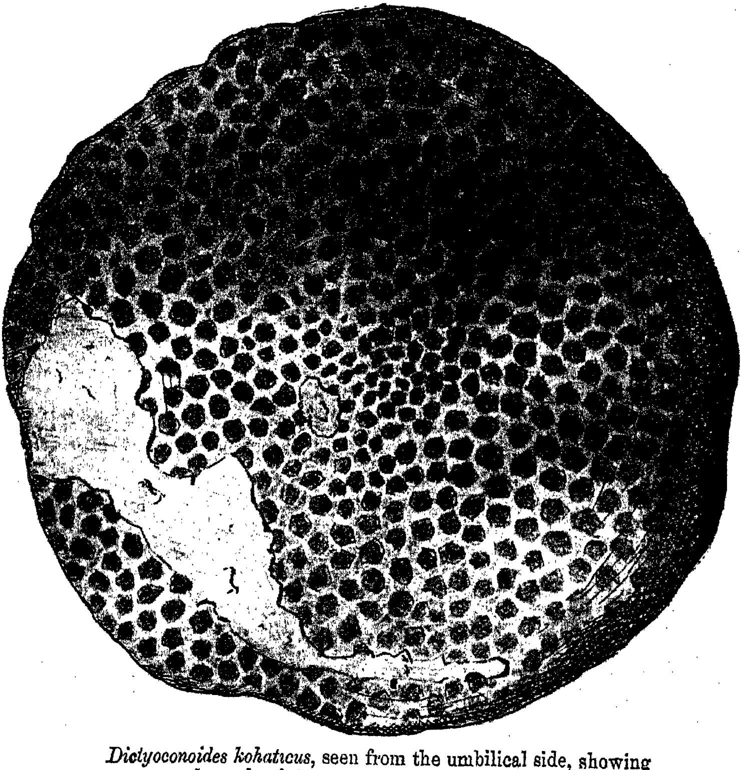
The third form is a much more flattened type of 8 and more mm. basal diameter, while the conical height never attained 2 mm. and usually was about 1 mm. (Pl. VI. figs. 2 *a*, *b*).

Text-fig. 1.



Dictyoconoides kohaticus. Cross-section through the embryonic apparatus. Megalospheric type. × 80.

Text-fig. 2.

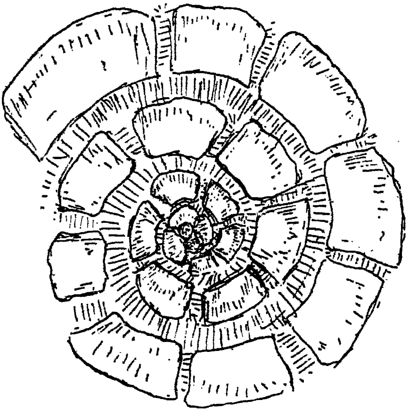


Dictyoconoides kohaticus, seen from the umbilical side, showing the ends of the umbilical "pillars." × 15.

The section, horizontally through the embryonic apparatus, showed a microspheric first chamber (text-fig. 3).

It was not always easy to decide whether an individual belonged to the effilated or the flattened conical type. But that does not appear to be astonishing, for if Hofker's ideas about the subject are correct, there must needs be a large series of individuals, which, although belonging to the megalospheric generations, show more or less slight gradations and variations towards the microspheric type.

Text-fig. 3.



Dictyoconoides kohaticus. Cross-section of the microspheric embryonic apparatus. × 80.

But they are always distinctly separated from the true microspheric generation. In a hundred specimens of *Dictyoconoides kohaticus* there were nine microspheric individuals, seven megalospheric high conical and eighty-four megalospheric lower conical individuals—an abundance of the intermediate megalospheric form that might be expected on the theory of heterogamy (trimorphism).

With regard to the description of the outer habitus of the species, I may refer to the original description of Davies (L. M. Davies, " Remarks etc.," *l. c.* 1926, p. 241).

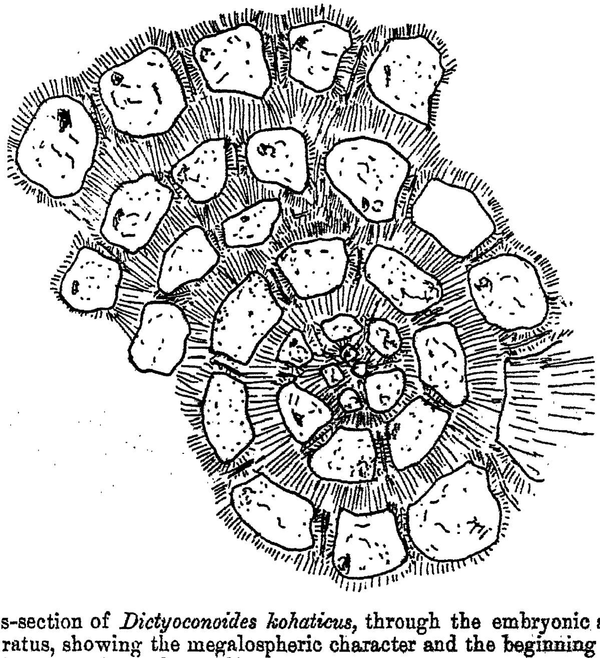
In horizontal section, the figure one can see is different, according to the height of the section.

The upper section shows the initial chamber and the first whorls of the chamber-spiral. The megalospheric individuals (text-figs. 1, 4) show distinctly a first chamber, followed by the rest of the chambers, which are all to be seen apart. The microspheric ones (text-fig. 3) show an initial chamber, with a first row of partly underlying, though spirally ranged, following chambers (the apparent disorder of the first four or five chambers does not form a "raspberry-apparatus," as is, for instance, the case in the Planorbulinidæ).

It is obvious that in the microspheric forms the first whorls show chamberlets of a much smaller size than the equivalent chambers of the megalospheric forms.

The walls are calcareous and distinctly, though finely, porous, and the septa between the chambers are penetrated by a canal, or rather (though this cannot be seen in a horizontal section) by a system of canals.

Text-fig. 4.

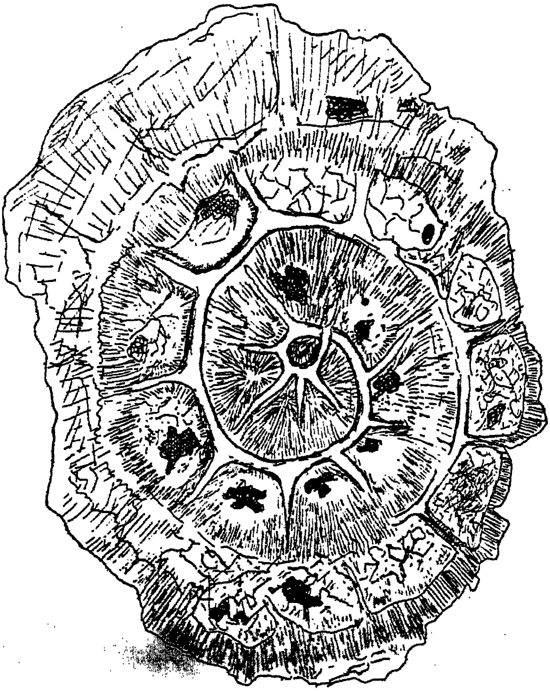


Cross-section of *Dictyoconoides kohaticus,* through the embryonic apparatus, showing the megalospheric character and the beginning of an intercalary whorl. × 60.

The origin of those canals is to be seen in a section cut immediately under the first whorls (text-fig. 5). There appears a beautiful spiral canal formed quite like that figured by Hofker in his work on the 'Siboga' Foraminifera (J. Hofker, "The Foraminifera of the 'Siboga' Expedition," *l. c.* pl. xix. figs. 12, 9, 4, and others). It branches off between the chambers.

As all the examined *Dictyoconoides* are fossilised specimens and during the fossilisation were totally filled up with calcite, it is not possible to apply here the "canada-balsam method" of Hofker. But in his habitus the spiral canal of *Dictyoconoides kohaticus* resembles perfectly that of *Rotalia schroeteriana* and *R. polystomelloides*, which are looked upon by Hofker as possessing a typically Rotalid canal-system. As in the forms here mentioned, the spiral canal runs on the umbilical side of the spiral of chambers, quite near to the chambers themselves. Besides, I could observe (near A in text-fig. 7) a bifurcating end of an interseptal canal. Here and there it was quite possible to observe the interseptal canals giving off their branches (text-fig. 6). So it does not appear unreasonable to conclude that the spiral canal-system is quite on the plan indicated in plate xix. fig. 4 of the already-mentioned 'Siboga' work of Hofker.

Text-fig. 5.



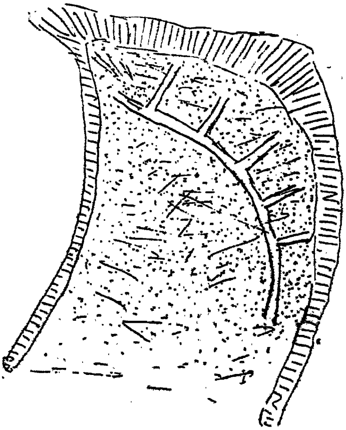
Cross-section of *Dictyoconoides kohaticus* just below the embryonic apparatus, showing the typical Rotalid spiral canal. × 60.

A yet lower cut section may reveal the secret of the structure of the umbilical canal-system, but, as I could better trace this in *Dictyoconoides vredenburgi*, I postpone the discussion of it until I describe that species.

A section not high above the base shows some spiral rings of chambers and cross-sections of the "columns" and interlocated "chamberlets" that form part of the umbilical system. I also postpone their interpretation till the discussion of *Dictyoconoides vredenburgi*.

A transverse section through the initial chamber (text-fig. 7) shows a cross-section of the chamber-spiral covered towards the outer whorl with a—near the top thickest—layer of finely perforated chalk-material, which bears here and there little outgrowths, in which one can now and then detect a bifurcation of the interseptal canal. Those granulations are not regularly spread, but generally they are more closely packed in the upper region.

Text-fig. 6.



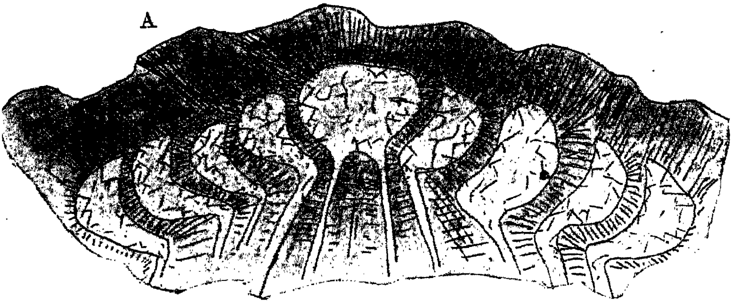
Section through septum, showing an interseptal canal with branches. × 180.

The chambers open at the base towards the umbilical region (text-fig. 8). From every chamber-wall emerges a basally directed pillar-shaped prolongation and a more horizontally directed wall. They are placed almost vertically to each other, and so the transverse section gives the impression of a chamber-filled umbilical region.

Yet by thoroughly studying, comparing, and combining horizontal and vertical sections, it must become clear that there can only be recognised a system of canals (umbilical canal-system) which are connected with the inner contents of the chambers. So I must decidedly oppose the opinion of Davies and other authors, who speak about the openings as "secondary chambers."

It is not easy to indicate on the transverse sections where the spiral canal has been cut, but that is not so strange, owing to the trifling width of the canal and the complete calcifying of the test.

Text-fig. 7.



Dictyoconoides kohaticus. Transversal section through the top, showing some chambers and a part of the umbilical region. Also the umbilical opening of the chambers and the upper part of the "pillars" are to be seen, as well as the thickness of the calcareous skin, with its granulations. Near A can be observed that canals end in those granulations. × 60.

As to the variety *spintangiensis*, I can see no clear difference between it and the microspheric form of *Dictyoconoides kohaticus.* Indeed, there are individuals of *D. kohaticus* and of the variety *spintangiensis*, both from the collection of Davies, which I cannot possibly distinguish from each other.

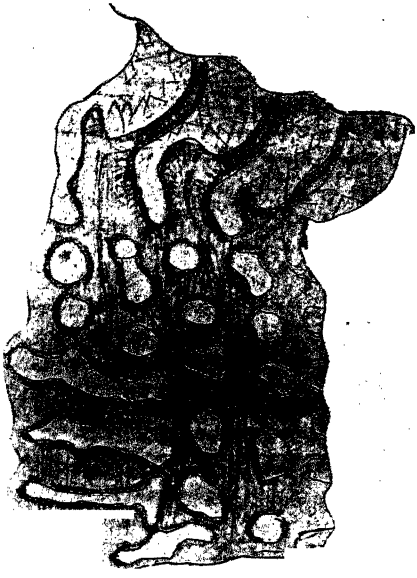
The differences which guided Davies in his creating the new species were (1) its being bigger, (2) its being flatter, than the normal type.

Davies adds: "This appearance of flatness is due to the thickening and turning upwards of the outer rim of the test."

It appears to me that these differences are not of so great an importance, as they show every gradation to the original species, and may not always be distinguishable from it with certainty.

Now, it is an essential fact, stated by Davies, that the variety *spintangiensis* always occurs with the original *Dictyoconoides kohaticus,* but is found in larger quantities in the southern parts of the district where *kohaticus* is found. He adds in an important note: "It is noticeable, though, that the specimens from Lower Sind, still further south, often approximate to the normal *kohaticus* type, rather than to the *spintangiensis* variety" (L. M. Davies, "Remarks etc.," 1926, *l. c.* p. 245).

Text-fig. 8.



Transversal section through *Dictyoconoides kohaticus* (part), showing part of the umbilical system and chambers. In the vertical "pillars" canals are running. × 60.

A remarkable fact, shown by sections of the variety *spintangiensis,* is that these forms are all microspheric, and there are no megalospheric specimens as would be expected if the variety *spintangiensis* really was a variety.

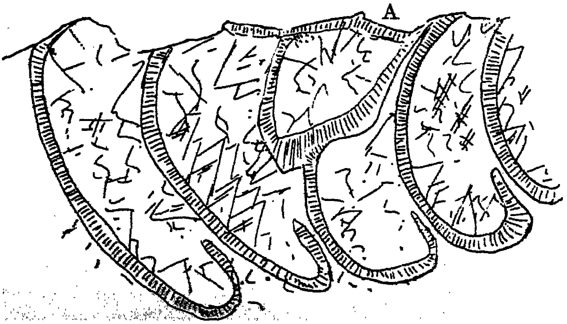
Besides the Spintangi-zone, where the variety has been found in larger quantities, has some peculiarities, so that it usually is placed in the lower Khirthar, which immediately follows the Laki-series. Davies is inclined to determine the strata as a *special facies* of the uppermost Laki and basal Khirthar series.

So, on the whole, I am inclined to consider *Dictyoconoides kohaticus*, var. *spintangiensis*, Davies, as a microspheric *Dictyoconoides kohaticus*, Davies, that may perhaps in the special life-circumstances of the Spintangi-facies have developed some deviating qualities in outer shape.

I could not quite make out the difference between *D. kohaticus* and *D.* (*Conulites*) *cooki*, Carter. It seems that Davies also had some doubts as to the difference between those two species (L. M. Davies, " Remarks etc.," 1926, *l. c.* pp. 243–244). Davies tried to check his opinion by studying the type-specimens of Carter, but they proved to be lost. So he could not confirm his opinion in this way.

Of course, I cannot decide here, but I should not be much surprised if *Dictyoconoides cooki*, Carter, proved to be nothing else than the megalospheric high conical form of *D. kohaticus*, Davies. But as long as there is no actual proof of this surmise, we must distinguish the two species.

Text-fig. 9.



Dictyoconoides vredenburgi. Transversal section, shewing some of the chambers, with their openings towards the umbilicus and near A the beginning of an intercalary whorl. The chambers are filled up with calcite crystals. × 80.

Dictyoconoides vredenburgi, Davies.

Conulites vredenburgi, Davies (L. M. Davies, " Remarks on Carter's Genus *Conulites* etc.," Records of the Geol. Survey of India, vol. lix. part 2, 1926, p. 246, pl. xvii. figs. 7–7 *b*).

Davies says about this species that it differs specifically from *D. kohaticus*. " It is a relatively small flat form, with cortical chambers so large in proportion to the test as a whole, as to constitute in my opinion a specific difference in type " (L. M. Davies, " Remarks," 1926, *l. c.* p. 247).

This is really an obvious difference from *kohaticus*, the more so, since—as Davies also states—there are no gradations between this type and *D. kohaticus*.

It also does not always occur amidst the other Foraminifera; it is found by Davies in one place only.

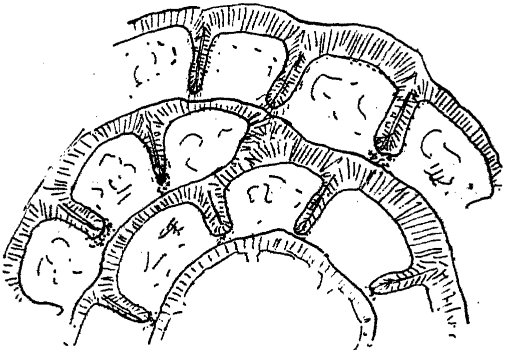
Examining the received sample (altogether six specimens) it was possible to distinguish a flat and a more conical type, and a slide demonstrated that the flat individual belonged to the microspheric generation, the more conical to a megalospheric one.

For these reasons I quite agree with Davies in considering it as a species different from *kohaticus.*

The inner structure—except the bigness of the chambers—did not demonstrate any difference from that of *Dictyoconoides kohaticus.* Here also the spiral canal could be traced in its typical Rotalid development.

A transverse section showed the structure known already from *D. kohaticus.* Only the connection of the chamber-contents with the umbilical canal-system was very clearly demonstrated here (figs. 8, 9). One wall strongly curves to the umbilical side and runs a little distance upward, parallel to another wall. Through the opening thus formed between them the communication is created. Also two "pillars" of calcareous material run, one vertically, the other more horizontally, which border a system of openings, the umbilical canal-system, that by the fore-mentioned ventral opening communicates with the chamber. In this transverse section, too, it is difficult to indicate where the spiral canal runs. In horizontal section it runs beneath the marginal walls between two whorls (cf. *Rotalia schroeteriana*).

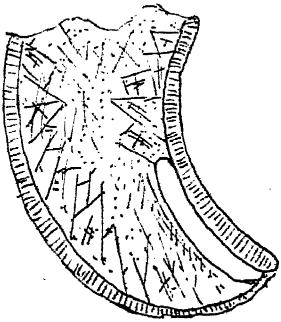
Text-fig. 10.



Cross-section showing the connection of the chambers by the apertures and the beginning of an intercalary whorl. × 80.

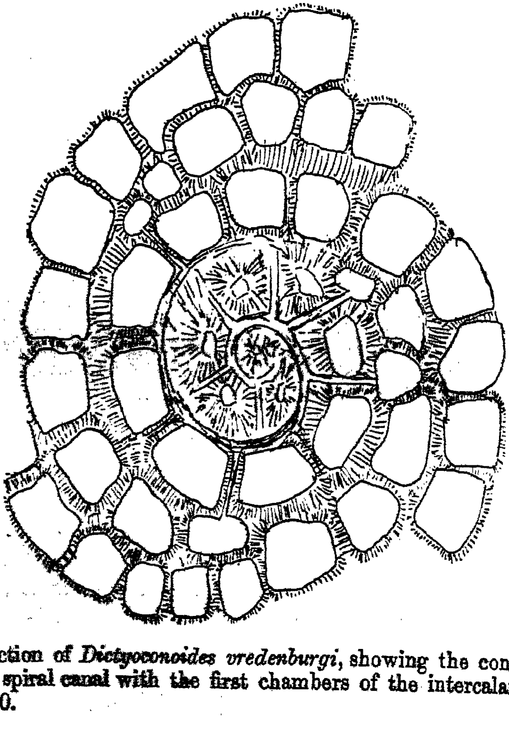
Pl. V. shows a reconstruction of a part of a *Dictyoconoides vredenburgi.* It does not greatly differ from *D. kohaticus.*

Text-fig. 11.



Section through septum, showing the aperture. × 120.

Text-fig. 12.



Cross-section of *Dictyoconoides vredenburgi*, showing the connection of the spiral canal with the first chambers of the intercalary whorls. × 60.

In one horizontal slide I thought I could—though not with the greatest certainty—see something of the genesis of the intercalary whorls (text-figs. 9, 10, and 12).

One of the branches of the spiral canal—an interseptal one—seemed to pass straight on to the first chamber of the intercalary whorl wherein it opened.

In the cross-section here published (text-fig. 12) there is one place in the regular arrangement of the chambers where it seems that two chambers struggle for a place in the spiral, one lower, the other higher. The interpretation may be that—by what cause is not clear—a chamber is formed at the end of the branch of the spiral canal near the last chamber of the existing whorl. The forming of the first intercalary chamber and a new chamber of the original spiral are simultaneous and one chamber displaces the other. In the forming of the next two chambers this process is continued, and so, finally, the intercalary whorl has assumed its place amidst the original ones. I should not like this to be considered a certainty, but I give it as a possibility that, in my opinion, has some probability.

Conclusions.

We can gather the following facts from the notes given above:—

1. Hitherto especially the outer shape has been used to classify *Dictyoconoides*.
2. *Dictyoconoides* possesses a typical Rotalid canal-system, *i. e.*, a spiral canal, with branches towards the umbilicus and in the septa. The branches in the septa bifurcate in many places and the branches in the umbilicus are part of the "umbilical canal-system" that corresponds with the chambers.
3. *Dictyoconoides* also shows other Rotalid characteristics: a spiral of chambers, conical shape, finely perforate walls, a closed umbilicus.
4. So *Dictyoconoides* must be considered to be a Rotalid.
5. The above-mentioned characteristics classify *Dictyoconoides* as a typical *Rotalia*.
6. The name *Dictyoconoides* is to be replaced by the name *Rotalia*.
7. *Rotalia kohaticus*, Davies, typically shows *trimorphism*.

EXPLANATION OF THE PLATES.

X.—*New or little-known* Tipulidæ (*Diptera*).—XLIV. *Australasian Species.* By Charles P. Alexander, Ph.D., F.E.S., Massachusetts Agricultural College, Amherst, Massachusetts, U.S.A.

The crane-flies discussed in this paper are from Queensland, New South Wales, Victoria, and West Australia, and were collected by my friends Messrs. Clark, Davidson, Dodd, Ferguson, Heron, Mathews, Perkins, Taylor, and Wilson, to whom my deepest thanks are extended. Where not indicated to the contrary, the types of the novelties are preserved in my collection.

Dolichopeza (*Dolichopeza*) *illingworthi*, sp. n.

Thorax almost uniform fulvous-yellow, the pleura paler yellow; legs brown, the genua scarcely brightened; posterior tibiæ broadly white at tips; fore and middle basitarsi brown, the tips white; posterior basitarsi pure white; wings whitish subhyaline, the apex and a narrow seam on anterior cord dark brown; abdominal segments black, ringed at near mid-length with ochreous.

Male.—Length about 7·5 mm.; wing 7–7·5 mm.

Frontal prolongation of head obscure yellow, the palpi dark brown. Antennæ (♂) of moderate length, if bent backward extending to beyond the base of the abdomen; scapal segments obscure yellow, the flagellum dark brown. Head dark brown, the anterior portion more brownish yellow.

Thorax almost uniform fulvous-yellow, the mesonotum immaculate, the pleura clear yellow, palest ventrally. Halteres elongate, pale brown, the knobs dark brown. Legs with the coxæ and trochanters pale brown; femora brown, the bases paler, the genua scarcely brightened; tibiæ dark brown, the distal third of posterior tibiæ snowy white; basitarsi dark brown, the tips and remainder of tarsi snowy white; on posterior legs the tarsi are uniformly whitened. Wings whitish hyaline, the apex narrowly dark brown; stigma and a narrow seam on anterior cord dark brown; veins brownish black. Venation: cells of medial field relatively shallow; *m–cu* nearly its own length before fork of *M*; cell *2nd A* very narrow on basal half, the outer half more expanded to form a weak anal angle.

Abdomen black, the segments ringed with ochreous at or beyond mid-length; hypopygium chiefly ochreous, relatively large. Male hypopygium with the tergite nearly transverse, with an acute spine on either side, the space between nearly transverse, in its median portion produced caudad into a low transverse median lobe. Outer dististyle toothed on mesal face shortly before apex.

Hab. North Queensland.

Holotype, ♂, Kuranda, Cairns District, altitude 1100 feet, on window, March 1921 (*A. P. Dodd*).

Paratopotype, ♂.

I take great pleasure in naming this interesting species in honour of Dr. James F. Illingworth, to whom I am indebted for many Tipulidæ from the Cairns District. The species is allied to *D. varipes*, Skuse, differing especially in the details of coloration and structure of the male hypopygium.

Dolichopeza (*Dolichopeza*) *davidsoni*, sp. n.

General coloration dark brown; pleura pale yellow, variegated with dark brown; legs brown, the femoral tips, tibial bases and tips, extreme proximal ends of basitarsi, and the outer tarsal segments white; wings greyish, the apex and veins beyond cord conspicuously infumed; abdominal tergites dark brown, the outer sternites ringed with yellow.

Male.—Length about 6·5 mm.; wing 7·2–7·4 mm.

Female.—Length about 8 mm.; wing 7·7 mm.

Frontal prolongation of head brownish yellow, dark brown ventrally; palpi dark brown. Antennæ with the scape and basal segments of flagellum pale yellow, the outer segments dark. Head brown, with a sparse grey pruinosity, the anterior vertex and front restrictedly light yellow.

Pronotum light yellow, the cervical sclerites dark brown. Mesonotal præscutum dark brown, the usual stripes scarcely evident, confluent, the humeral region restrictedly light yellow; scutal lobes dark brown, the median region very restrictedly pale; scutellum and postnotum uniformly brown. Pleura pale yellow, conspicuously variegated with dark brown, this including the anepisternum, together with the dorso-pleural region immediately dorsad of it, the ventral sternopleurite, and the meron. Halteres elongate, pale, the knobs dark brown. Legs with the coxæ and trochanters pale yellow; femora pale basally, deepening into brown outwardly to produce a darker subterminal ring, the tips narrowly whitened; tibiæ dark brown, the bases narrowly whitened, the tips broadly pure white; proximal ends of basitarsi more or less whitened, especially evident on the type, where on the hind legs it includes an area only slightly less than the tibial apex; remainder of basitarsi dark brown, the tips and tarsal segments 2 to 4 white; terminal segment infuscated. Wings with a greyish tinge, cells *C* and *Sc* a little darker; stigma elongate, dark brown; wing-apex broadly infumed, connected by broad seams along the veins with a large seam on the anterior cord; medial veins, *m–cu*, and distal section of Cu_1 similarly seamed; whitish areas before and beyond the stigma; veins dark brown, more cream-coloured in the pre-stigmal pale area. Venation: forks of medial field relatively shallow; *m–cu* more than two-thirds its own length before the fork of *M*; cell *2nd A* narrow.

Abdominal tergites uniformly dark brown; basal sternites pale yellow, narrowly ringed with dark brown; subterminal segments with the caudal margins of the segments yellow, the amount increasing on the outer segments. Ovipositor with the genital shield and basal half of the tergal valves blackened, the tips of the latter and the sternal valves pale yellow.

Hab. South Queensland, New South Wales.

Holotype, ♀, Mt. Tamborine, South Queensland, altitude 2000 feet, November 1928 (*W. H. Davidson*).

Allotype, ♂, Eastern Dorrigo, New South Wales, altitude 2000–3000 feet, February 27, 1929 (*W. Heron*).

Paratypes, ♂ ♀, with the allotype.

The species is named in honour of the collector of the type, Mr. Will H. Davidson. *Dolichopeza davidsoni* is allied to *D. annulipes*, Skuse, differing in the wing-pattern, coloration of the thoracic pleura, and details of the leg-pattern.

Dolichopeza (*Dolichopeza*) *dorrigensis*, sp. n.

General coloration dark brown; thoracic pleura with a broad oblique yellow stripe; legs dark brown, the genua, tips of all tibiæ, proximal ends of all basitarsi, and outer tarsal segments snowy white; wings greyish subhyaline, virtually unmarked except for the stigma; *m–cu* about one-third its length before the fork of *M*; abdominal tergites dark brown, with whitish-yellow lateral spots; sternites whitish yellow, with a median series of brown spots.

Female.—Length about 8 mm.; wing 7·8 mm.

Frontal prolongation of head pale yellow; palpi brown. Antennæ dark brown, including the scape; flagellar segments elongate-cylindrical, the verticils longer than the segments. Head rich cinnamon-brown, the anterior vertex and front light yellow.

Pronotum yellow laterally, narrowly dark brown behind. Mesonotum brown, the humeral region of the præscutum restrictedly pale yellow, the scutal region a little brightened. Pleura obliquely lined with pale yellow and dark brown, the yellow band extending from the humeral region to the posterior coxæ, margined in front by a narrow brown line, margined posteriorly by a somewhat wider line of the same colour; propleura extensively pale yellow. Halteres dusky, the knobs dark brown. Legs with the coxæ pale yellow, the base of the fore coxa darkened; trochanters yellow; femora dusky at base, passing into dark brown, the genua narrowly but conspicuously white; tibiæ dark brown, the tips of all legs conspicuously snowy white, broadest on the hind legs; proximal ends of basitarsi narrowly but conspicuously white, the major portion dark brown, the tips again white; remainder of tarsi white. Wings greyish subhyaline, the stigma conspicuously dark brown; a vague, scarcely indicated brown seam on anterior cord; pale areas before and beyond the stigma scarcely indicated; wing-margin in cell Sc_2 narrowly infumed; veins dark brown. Wing rather conspicuously petiolate. Venation: Sc_1 distinctly preserved; forks of medial field relatively deep; *m–cu* at about one-third its length before the fork of *M*; cell *2nd A* unusually long and narrow.

Abdominal tergites dark brown, each segment with a conspicuous yellow lateral spot on posterior ring; sternites greenish, the median portion extensively yellow, with a conspicuous series of brown markings distributed the entire length; in certain lights the yellow coloration of the abdomen is conspicuously white pruinose. Ovipositor with the valves chiefly yellow; tips of the short sternal valves broadly and conspicuously blackened.

Hab. New South Wales.

Holotype, ♀, Brooklana, East Dorrigo, altitude about 2000 feet, March 3, 1928 (*W. Heron*).

Dolichopeza dorrigensis is allied to *D. annulipes*, Skuse, differing in the details of coloration of the wings, legs, and abdomen.

Macromastix (*Macromastix*) *clitellaria*, sp. n.

General coloration of mesonotal præscutum and scutal lobes polished black (♂), more obscurely darkened (♀); postnotal mediotergite yellowish testaceous, with two black spots on caudal margin; legs long and slender, black, the femoral bases broadly obscure yellow; wings with a strong dusky suffusion, the prearcular region and cells *C* and *Sc* dark brown; base of abdomen (♂) fulvous-yellow, the terminal portion black.

Male.—Length about 11–12 mm.; wing 15 mm.

Female.—Length about 10·5–11 mm.; wing 13·5 mm.

Frontal prolongation of head of moderate length only, a little more than one-half the remainder of head, dark brown, paler at apex; nasus very long and slender, tufted with conspicuous setæ; palpi black. Antennæ short, only about as long as the head excluding the frontal prolongation, apparently only 11-segmented; first scapal segment obscure yellow, darkened dorsally; second scapal segment light yellow; flagellum black, the base of the first segment paler; first flagellar segment subpyriform, the succeeding segments becoming more slender; verticils short and inconspicuous. Head dark brown, the posterior orbits narrowly and irregularly light grey.

Pronotum black, pollinose. Mesonotal præscutum (♂) with an extensive polished black dorsal shield, the narrow lateral margins yellowish-grey pruinose; scutal lobes similarly polished black; median area of scutum, the scutellum, and most of the postnotal mediotergite yellowish testaceous, the caudal margin of the latter with two paired black spots. In the female the polished areas of the male are dull, being covered with a sparse pollen. Pleura heavily light grey pruinose, including the dorso-pleural region; pleurotergite with the dorsal portion pale, pruinose, the ventral portion clearer grey. In the female the dorsal portion of the pleurotergite is glabrous. Halteres brownish yellow, the knobs infuscated. Legs with the coxæ light grey; trochanters obscure yellow; femora chiefly black, their bases broadly obscure yellow, the amount of the latter somewhat more extensive on the middle and posterior femora; remainder of legs black; legs very long and slender, the posterior basitarsi longer than the tibiæ. Wings with a strong dusky suffusion, the stigma and cell Sc_1 more yellowish; prearcular region and cells *C*, *Sc*, and small adjoining cells dark brown; veins black, the obliterative areas relatively restricted; distal end of R_{1+2} entirely pale; *Rs* entirely pale brown, without macrotrichia. Macrotrichia lacking on veins beyond the cord, with the exception of *Sc* and R_1. Venation: R_3 nearly in alignment with R_{2+3}, the latter subequal to *Rs*; cell M_1 deep, the petiole subequal to or longer than *m*; cell *2nd A* very narrow.

Abdomen with the basal segments fulvous-yellow, the distal half or less black, the outermost segments pruinose; sternites similarly coloured; hypopygium entirely dark. In the female the abdominal tergites are very extensively covered with a yellowish-grey pruinosity, only the base of tergite 2 being nitidous; basal sternites more extensively glabrous.

Hab. Victoria.

Holotype, ♂, Bogong High Plains, altitude 5600–6000 feet, January 1928 (*F. E. Wilson*).

Allotopotype, ♀.

Paratopotypes, 2 ♂ ♂.

Type returned to Mr. Wilson.

Macromastix (*Macromastix*) *mathewsi*, sp. n.

Male.—Length 11–14 mm.; wing 13–15 mm.

Female.—Length 8·5–12 mm.; wing 9·5–14 mm.

Allied to *M. constricta*, Skuse (New South Wales), differing especially in the details of coloration and structure.

Frontal prolongation of head a little shorter than in *constricta*, opaque by a conspicuous microscopic yellow pubescence, obscure yellow with a narrow dark brown or black lateral line; nasus shorter; palpi black. Antennæ with the scape yellow, the flagellum entirely black. Head yellowish grey.

Mesonotal præscutum yellowish grey, opaque, with four poorly delimited brownish-grey stripes, the intermediate pair confluent and more greyish behind; scutellum and postnotum with an abundant appressed yellowish pubescence. Pleura conspicuously light grey, including the anepisternum, sternopleurite, and pteropleurite, the pleurotergite abruptly yellowish. Halteres dark brown, the stem paler. Legs with the coxæ greyish, the mid-coxæ more clearly so; trochanters obscure yellow; femora yellow, the tips broadly blackened, this including approximately the distal fourth; tibiæ brownish yellow, the bases very narrowly, the tips broadly blackened; tarsi black; all tarsi relatively short, as in *constricta*. Wings broader than in *constricta*, strongly infumed, the base and costal border darker, but not contrasting so conspicuously with the remainder of the wing. Venation: cell *2nd A* narrow, but still much wider than in *constricta*.

Abdominal tergites (♂) dark brown, the basal segments yellow on lateral margins, this narrowing behind; sternites yellow, the subterminal segments black, sparsely pollinose;

hypopygium pale. In the female the abdomen is heavily pruinose, the lateral margins and ovipositor fulvous.

Hab. West Australia.

Holotype, ♂, South Perth, October 20, 1927 (*W. H. Mathews*).

Allotopotype, ♀, September 22, 1927.

Paratopotypes, numerous ♂ ♀, September 22, 1927; October 20–30, 1927; *paratypes*, ♂ ♀, Redlands, September 11, 1927 (*W. H. Mathews*).

"All caught in my garden on the side of a small hill."

I take great pleasure in naming this species in honour of the collector, Mr. Wallace H. Mathews. Although closely allied to *M. constricta*, the present species is clearly distinct. The most conspicuous differences lie in the frontal prolongation of the head, the wings, and coloration of the male hypopygium.

Macromastix (*Macromastix*) *clarkiana*, sp. n.

Male.—Length about 12–13 mm.; wing 15–16 mm.

Female.—Length about 13 mm.; wing 15 mm.

Closely allied to *M. constricta*, Skuse (New South Wales), agreeing in the general coloration of the body and wings, differing in the details of pattern and structure.

Frontal prolongation of head slender, as in *constricta*, but slightly less constricted before mid-length, chestnut-brown. Antennæ with the scape bright yellow, the flagellum black; flagellar segments beyond the fourth narrowed and shortened, the terminal seven shorter than the preceding four taken together. Two more or less distinct brown spots between the eyes.

Ground-colour of the præscutum yellowish grey, clearer laterally, with four entirely separated brown stripes; scutellum and postnotal mediotergite conspicuously yellow pollinose. Pleura chiefly clear grey. Legs with the femora and tibiæ fulvous, tips broadly blackened; tarsi relatively short, as in *constricta*. Wings with a strong dusky grey ground-colour, the pattern distinct from *constricta*; prearcular region darkened, the costal region rather narrowly of the same colour, the amount decreasing toward the stigma, which is chiefly yellow; in cell *R* only about the basal half of the cell is darkened; no distinct dark seam in cell *M* adjoining vein Cu_1, except at base; cell Cu_1 and adjoining portions of cells *M* and *Cu* conspicuously light cream-yellow; veins dark. Wings broader than in *constricta*, especially in the anal region. Venation: cell *2nd A* narrower than in *mastersi*, but broader than in *constricta*.

Abdomen as in the group, the basal segments yellow, the apex, including hypopygium, black. In the female the abdominal tergites are more greyish, with a broad dark brown sublateral stripe on either side; basal segments laterally and the genital segments fulvous-yellow; sternites yellow, the caudal margins of sternites 5 and 6 light grey. Male hypopygium as in *constricta*, but inner dististyle, at base of the elongate rod-like extension, provided only with setæ or weak spines. In *constricta* this region of the style is provided with a small group of short black spines.

Hab. Victoria.

Holotype, ♂, Cann River, November 1928 (*J. Clark*).

Allotopotype, ♀.

Paratopotypes, several ♂ ♀.

Type in the National Museum, Victoria.

I take great pleasure in naming this species in honour of the collector, Mr. John Clark.

Limonia (*Geranomyia*) *bogongicola,* sp. n.

General coloration reddish yellow, heavily variegated with black; rostrum moderately elongate; femora brownish yellow, the tips broadly blackened; wings whitish to yellow, with a brown pattern; male hypopygium with the spines of the short rostral prolongation of the ventral dististyle of moderate length, but exceeding the prolongation itself.

Male.—Length (excluding rostrum) about 8–9 mm.; wing 8·5–10 mm.; rostrum about 3 mm.

Female.—Length (excluding rostrum) about 12–13 mm.; wing 10·5–11·5 mm.; rostrum about 4 mm.

Rostrum black, including the maxillary palpi, the latter 3-segmented; rostrum of moderate length only; subequal to the combined head in thorax in male, somewhat longer in the female. Antennæ black throughout, the basal segments weakly pruinose; flagellar segments cylindrical, the outer segments gradually increasing in length. Head black, pruinose.

Pronotum black, pruinose, restrictedly obscure reddish laterally. Mesonotal præscutum deep reddish, with three broad black stripes that restrict the interspaces; scutum brownish black; scutellum abruptly pale yellow, with a dark basal median spot; postnotal mediotergite dark brown, sparsely pruinose, the antero-lateral portions obscure yellow. Pleura chiefly black, sparsely pruinose, with vague indications of paler areas. Halteres yellow, the knobs weakly infumed, the stem fringed with setæ. Legs with the coxæ dark brown, more yellowish apically, the posterior coxæ more extensively so; trochanters obscure yellow; femora yellow basally, darker outwardly, the tips broadly blackened, in cases with a very indistinct pale apex; tibiæ brown, the tips blackened; tarsi black. Wings whitish subhyaline, more yellowish in female, with a restricted dark pattern, including the stigma, clouds at origin of *Rs*, Sc_2, along the cord and outer end of cell 1*st* M_2; additional paler washes in the medial, cubital, and anal cells. In the female the ground-colour is more yellowish and the pattern is heavier, including the broad apex and more distinct cloudings in the cubital and anal cells. Costal fringe relatively long and conspicuous in both sexes. Venation: Sc_1 ending opposite two-thirds to three-fourths the length of *Rs*, Sc_2 at its tip; *m–cu* close to the fork of *M*.

Abdominal tergites black, the caudal margins of the segments narrowly and indistinctly silvery; sternites more brownish, the caudal and lateral margins dark; hypopygium yellowish brown. Male hypopygium with the ninth tergite transverse, the caudal margin convex with the median area very gently emarginate. Ventral dististyle with the rostral prolongation short and stout, the two spines arising from tubercles that are placed close together, the spines longer than the entire prolongation. Ædeagus with the surface set with microscopic tubercles. Gonapophyses with the mesal apical lobe relatively prominent, the outer margin with microscopic denticles.

Hab. Victoria.

Holotype, ♂, Bogong High Plains, altitude 5600–6000 feet, January 1928 (*F. E. Wilson*).

Allotopotype, ♀.

Paratopotypes, 1 ♂, 1 ♀.

Type returned to Mr. Wilson.

The species is most closely allied to *L.* (*G.*) *risibilis* (Alexander), differing especially in the diagnostic features listed above.

Limonia (*Geranomyia*) *grampianicola*, sp. n.

Male.—Length (excluding rostrum) about 6·5 mm.; wing 7·5 mm.; rostrum about 2 mm.

Female.—Length (excluding rostrum) about 8 mm.; wing 8·5 mm.; rostrum about 2·4 mm.

Closely allied and generally similar to *L.* (*G.*) *risibilis* (Alexander), differing in the details of coloration and structure of the male hypopygium.

Rostrum of moderate length only, black, including the palpi. Antennæ black throughout. Head chiefly grey, the vertex with an extensive velvety-black area on either side of the median line, these areas narrower than the median region.

Mesonotal præscutum with three conspicuous black stripes, the median one broadest and most intense in front, the posterior portion and lateral stripes paler, the lateral areas crossing the suture on to the scutal lobes; median region of scutum and the scutellum extensively pale. Pleura chiefly yellow, the anepisternum and sternopleurite more infuscated, the dorso-pleural region dusky. All femora with black rings, most extensive on the fore femora, where they are nearly apical, there being only a restricted brightening beyond; on the other legs the pale femoral tups are subequal or a little shorter than the dark rings. Wings pale yellow, with a restricted brown pattern, including, besides the stigma, a small spot on Cu_1 near base, a rectangular area at origin of Rs, Sc_2, seams along cord and outer end of cell 1*st* M_2; a grey marginal wash in cell 1*st* *A*; veins black, *C*, *Sc*, *R*, *Cu*, and the prearcular veins pale. Venation: *Rs* strongly arcuated to angulated and short-spurred at origin; R_3 very long, approximately twice cell 1*st* M_2; cell 1*st* M_2 relatively short and broad, widened outwardly, at distal end about two-thirds as wide as long; *m–cu* variable in position, from one-fifth to approximately one-half its length before the fork of *M*.

Male hypopygium with the dorsal dististyle slender, the distal portion sinuous, the slender tip decurved. Rostral prolongation of ventral dististyle stout, the spines blackened, one arising from a low tubercle, the other more nearly sessile. Gonapophyses with the mesal apical lobe long and slender, their margins smooth. In *risibilis* the dorsal dististyle is differently formed, the rostral prolongation is stouter, and the spines are not blackened.

Hab. Victoria.

Holotype, ♂, Grampians, in fern-gully, October 1928 (*F. E. Wilson*).

Allotopotype, ♀.

Type returned to Mr. Wilson.

L. (*G.*) *annulata* (Skuse) has a somewhat similar leg-pattern, but a very different hypopygium.

Limonia (*Limonia*) *clarki*, sp. n.

General coloration dark grey, the pleura more or less distinctly striped; legs black, the femoral bases paler; wings with a strong brown suffusion, the oval stigma dark brown;

Sc relatively short, Sc_1 ending a short distance beyond the origin of *Rs*.

Male.—Length about 5–5·5 mm.; wing 6 mm.

Female.—Length about 7·5–8 mm.; wing 7–8 mm.

Rostrum elongate, nearly equal to the remainder of the head, black. Antennæ black throughout. Head grey, the posterior vertex infuscated on either side of the median line.

Pronotum and mesonotum dark brown, pruinose, especially laterally; præscutum with a broad median and narrower lateral brown stripes; median region of scutum, scutellum, and postnotum more heavily pruinose. Pleura grey, the dorso-pleural region darker brownish grey; dorsal portion of the sternopleurite paler. In some paratypes the pale pleural stripe is very evident. Halteres pale, the knobs dark brown. Legs with the coxæ brown; trochanters brownish yellow; femora pale basally, passing into black; tibiæ and tarsi black. Wings with a strong brown suffusion; stigma oval, dark brown; narrow vague dusky seams along cord, outer end of cell *1st* M_2, vein *Cu*, and the longitudinal veins beyond cord; veins dark brown. Venation: Sc_1 ending a short distance beyond the origin of *Rs*, Sc_2 at its tip; *Rs* relatively long, angulated near origin; *m–cu* at or close to the fork of *M*.

Abdominal tergites brownish black; sternites more pruinose, the basal sternites paler medially and on caudal margin; hypopygium chiefly dark, the ventral dististyle pale. Male hypopygium with the tergite transverse, the caudal margin gently emarginate. Basistyle with the ventro-mesal lobe low and stout. Ventral dististyle smaller than the basistyle, with a conspicuous cylindrical rostral prolongation that bears two long spines, one slightly more distal in position, a little shorter than the inner; both spines lie in an oval pale depression, the more basal spine from a short enlarged base. Dorsal dististyle a strongly chitinized black hook, the slightly decurved apex acute; margin of curvature of the style with small delicate setulæ. Gonapophyses broad-based, the mesal apical lobe slender.

Hab. West Australia.

Holotype, ♂, Mundaring, August 23, 1926 (*E. W. Ferguson*).

Allotype, ♀, Balingup, August 29, 1926 (*E. W. Ferguson*).

Paratopotypes, 7 ♂ ♀ (*E. W. Ferguson* and *J. Clark*); *paratypes*, 3 ♂ ♀, with the allotype (*E. W. Ferguson*); 4 ♂ ♀, Pemberton, August 28, 1926 (*E. W. Ferguson*); 1 ♂, Donnybrook, August 29, 1926 (*E. W. Ferguson*).

Type in the Macleay Collection.

Limonia clarki is respectfully dedicated to Mr. John Clark, in recognition of his valuable studies on the entomology of West Australia. The species is allied to *L.* (*L.*) *incisuralis* (Skuse) and *L.* (*L.*) *zonata* (Skuse), but is very distinct.

Limonia (*Limonia*) *tamborina*, sp. n.

General coloration yellow, the posterior præscutum and scutum dark brown; scutellum conspicuously whitish; pleura yellow, striped longitudinally with brown; knobs of halteres yellow; femora with a subterminal dark ring, the tips pale; wings cream-coloured, with a sparse dark pattern; *Sc* relatively short, Sc_1 ending shortly before mid-length of the angulated *Rs*; abdominal segments bicolorous, the bases obscure yellow, the apices more narrowly dark brown; male hypopygium with the mesal lobe of basistyle very long and slender, narrowed to an acute chitinized point.

Male.—Length about 5 mm.; wing 6 mm.

Rostrum and palpi black. Antennæ black throughout; flagellar segments oval, with a dense white pubescence and relatively inconspicuous setæ. Head dark brownish grey.

Mesonotum chiefly yellow, the præscutum behind with three confluent brownish stripes; scutal lobes dark brown; median area of scutum and the broad scutellum conspicuously whitish; postnotal mediotergite pale whitish yellow. Pleura yellow, with a broad dorso-longitudinal brown stripe that extends from the propleura, passing beneath the wing-root and across the pleurotergite to the abdomen; sternopleurite similarly darkened, producing a short ventral stripe. Halteres dusky, the knobs yellowish. Legs with the fore coxæ dark brown on outer face at base, forming part of the dorsal stripe; remaining coxæ and trochanters pale yellow; legs relatively long and slender, femora obscure yellow, darkened beyond base, gradually deepening to a narrow, dark brown, subterminal ring, the extreme tip again abruptly yellow; tibiæ obscure yellow, brightest at base, the tips darkened; tarsi brown. Wings with a creamy ground-colour, with a sparse dark pattern; stigma oval, brown; the brown clouds include conspicuous seams at Sc_2, origin of *Rs*, cord and outer end of cell 1*st* M_2; a broad diffuse seam in cell *M* adjoining vein Cu_1, becoming obsolete at mid-length of the cell; veins dark, more yellowish in the costal and prearcular regions. Costal fringe relatively short and inconspicuous. Venation: Sc_1 ends just before mid-length of *Rs*, Sc_2 longer, ending just beyond this point; *Rs* square at origin, weakly spurred ; R_2 and free tip of Sc_2 in transverse alignment ; inner end of cell R_3 lying far proximad of the other cells of cord ; cell 1*st* M_2 large, rectangular, as long as vein M_{1+2} beyond it ; *m–cu* shortly beyond the fork of *M*, subequal to the distal section of Cu_1.

Abdomen bicolorous, the bases of the segments obscure yellow, the tips more narrowly dark brown. Male hypopygium with the ventro-mesal lobe of the basistyle very long and slender, gradually narrowed to an acute chitinized point. Dististyle complex, trilobed ; what seems to correspond to the usual dorsal dististyle a short, nearly straight, pale rod, the apex narrowed and blackened ; main body of ventral dististyle a small fleshy lobe ; third branch corresponding to the rostral prolongation, this elongate, feebly chitinized, strongly curved at end, without rostral spines.

Hab. South Queensland.

Holotype, ♂, Mt. Tamborine, altitude 2000 feet, June 17, 1928 (*W. H. Davidson*).

Limonia (*Limonia*) *exosa*, sp. n.

General coloration of mesonotal præscutum yellow, with a brown median stripe ; posterior sclerites of mesonotum dark brown ; anterior vertex silvery ; antennæ relatively long, black ; wings with a distinct dusky tinge ; *Sc* long ; cell M_2 open by the atrophy of the basal section of M_3 ; *m–cu* at fork of *M* ; male hypopygium with the dorsal dististyle lacking ; ventral dististyle small, produced into a long arcuated chitinized blade.

Male.—Length about 3·6 mm. ; wing 4·5 mm.

Rostrum brownish yellow ; palpi brown. Antennæ dark brown throughout, of an unusual length for a member of this genus, if bent backward extending at least to the base of the abdomen ; flagellar segments long-oval, with a short, dark, glabrous, apical pedicel ; segments clothed with a dense white pubescence and short scattered verticils, the longest unilaterally arranged. Anterior vertex light silvery ; posterior portion of vertex dark brown, the posterior orbits light grey.

Pronotum brownish black. Mesonotal præscutum yellowish, with a broad brown median stripe that widens behind ; posterior sclerites of mesonotum dark brown. Pleura dark brown dorsally, the ventral portion paler. Halteres relatively long, dark brown, the base of the stem narrowly pale. Legs with the coxæ and trochanters yellowish testaceous ; femora light brown, the bases narrowly yellowish ; tibiæ pale brown; tarsi somewhat darker brown. Wings with a distinct dusky tinge, the oval stigma barely darker; veins brown, with relatively long, conspicuous, brown macrotrichia. Venation: Sc relatively long, Sc_1 extending to beyond mid-length of Rs, Sc_2 close to its tip; Rs weakly angulated at origin; free tip of Sc_2 and R_2 pale, the latter lying slightly more distad than the former; cell M_2 open by the atrophy of the basal section of M_3; *m–cu* at fork of M, a trifle shorter than the distal section of Cu_1; vein *2nd A* relatively elongate.

Abdomen dark brown, the eighth segment and hypopygium paler. Male hypopygium with the tergite strongly narrowed posteriorly, the caudal margin with a very low V-shaped notch. Ventro-mesal lobe of basistyle very large but low, applied to the whole mesal face of the style. Ventral distisyle small, oval, produced into a long arcuated chitinized blade. Dorsal dististyle lacking. Ædeagus very short and broad, the apex divided into two obtuse divergent lobes. Gonapophyses broad, the mesal apical angle produced into a long arcuated lobe that is gently widened outwardly, the tip obtuse.

Hab. New South Wales.

Holotype, ♂, Brooklana, Eastern Dorrigo, altitude 2000 feet, November 6, 1927 (*W. Heron*).

Paratopotypes, 6 ♂ ♂, February 1928 (*W. Heron*).

Limonia exosa is similar to *L. amicula* (Alexander) of North Queensland, differing in the diagnostic features given above.

Limonia (*Libnotes*) *tayloriana*, sp. n.

General coloration pale reddish yellow, the mesothorax unmarked with darker; head light grey; halteres and legs pale testaceous-yellow; wings subhyaline, the stigma subcircular, dark brown; veins pale, the cord and outer end of cell *1st* M_2 darker; male hypopygium with the spines of the rostral prolongation of the ventral dististyle very unequal in diameter.

Male.—Length about 5·5 mm.; wing 6 mm.

Rostrum moderately elongate, nearly as long as the remainder of head, pale brown; palpi obscure brownish yellow, 4-segmented. Antennæ dark brown; flagellar segments elongate-oval, each with a pair of outstanding verticils that are unilaterally arranged, these exceeding the segments in length. Head entirely light grey; eyes large, contiguous on vertex or virtually so.

Prothorax and mesothorax pale reddish yellow, entirely immaculate with darker; a whitish median line extends from the cephalic portion of the præscutum to the abdomen, widening out behind. Halteres short, pale. Legs pale testaceous-yellow, only the outer tarsal segments slightly darkened. Wings subhyaline, the base and costal region more yellowish; stigma small, nearly circular in outline, dark brown; veins pale yellow, the cord between the forks of *Rs* and *M* darkened; outer end of cell *1st* M_2 darkened; this dark coloration involves only the veins. Venation: *Sc* very long, Sc_1 extending to opposite *m–cu*; free tip of Sc_2 and R_2 in alignment; *Rs* about three times the basal section of R_{4+5}; cell *1st* M_2 elongate, the elements at outer end about in transverse alignment; *m–cu* at about two-fifths the length of cell *1st* M_2, subequal to the distal section of Cu_1; vein *2nd A* approaching *1st A* on the prearcular portion, thence gently sinuous and divergent.

Abdomen reddish yellow, the caudal margins of the segments narrowly and vaguely paler. Male hypopygium with the ninth tergite transversely rectangular, the caudal margin with a broad V-shaped notch, the lateral lobes with coarse conspicuous marginal setæ. Basistyle of moderate size, the mesal lobe low and obtuse. Ventral dististyle very large and fleshy, much larger than the basistyle; rostral prolongation relatively slender, with two spines that are very unequal in size, the outer spine placed just beyond mid-length of the prolongation, powerful and gently curved; inner spine near base of prolongation, very small and weak, setiform. Dorsal dististyle a curved chitinized rod, the apex acute. Ædeagus elongate, the apex with divergent flaps. Gonapophyses with the mesal apical angle long, slender, gently curved, the tip obtuse, the lateral margin with scattered pale spiculæ.

Hab. North Queensland.

Holotype, ♂, Mossman, March 1927 (*F. H. Taylor*).

Type in the Australian Institute of Tropical Medicine.

I take great pleasure in naming this species in honour of Mr. Frank H. Taylor, authority on the biting-flies of Australia. The fly is amply distinct from other regional species of *Libnotes*.

Limonia (*Dicranomyia*) *dicksoniæ*, sp. n.

General coloration brownish grey, the pleura clear blue-grey; antennæ black throughout; mesonotal præscutum with brown stripes, the median one more shiny black anteriorly; knobs of halteres infuscated; legs chiefly black;

wings grey, almost unmarked except for the stigma; *Rs* elongate, gently arcuate; male hypopygium with the tergite deeply emarginate medially.

Male.—Length about 6 mm.; wing 7 mm.

Female.—Length about 6·5 mm.; wing 8–8·2 mm.

Rostrum grey; palpi dark brown. Antennæ black throughout; basal flagellar segments subglobular, the outer segments passing to oval. Head light grey, the posterior vertex with a triangular dusky area on either side of a linear ashy median stripe; anterior vertex blue-grey, of moderate width.

Mesonotal præscutum dull yellowish grey, with three brown stripes, the median stripe more shiny black, especially in front; lateral stripes sometimes obsolete; posterior region of præscutum more brownish grey; scutal lobes brownish, the remainder of mesonotum clearer grey. Pleura clear blue-grey. Halteres of moderate length, pale, the knobs infuscated. Legs with the coxæ grey; trochanters brownish yellow; femora brown, the tips passing into dark brown or black; tibiæ and tarsi black. Wings relatively narrow, grey, the stigma oval, pale brown; scarcely indicated darkenings on other veins; cord and outer end of cell *1st* M_2 with extensive obliterative areas; veins dark brown. Venation: Sc_1 ending shortly before or beyond the origin of *Rs*, Sc_2 some distance before this tip; Sc_1 variable in length, from nearly as long as *m–cu* to considerably longer (♂); *Rs* long, gently arcuated, about twice the basal section of R_{4+5}; R_2 in approximate alignment with the free tip of Sc_2; *m–cu* shortly before the fork of *M*, usually from one-third to one-fourth its length.

Abdomen black, heavily pruinose, the hypopygium chiefly dark or obscure. Male hypopygium with the tergite large, the caudal margin deeply notched, the lateral lobes conspicuous, bordered with conspicuous setæ; a small transverse oval area on mid-length of tergite near caudal margin, this provided with two long and two more delicate setæ. Basistyle relatively large, the ventro-mesal lobe at its base, long and relatively narrow, provided with several stout flattened setæ in addition to smaller ones; at the base of this lobe a small tubercle set with about six long curved setæ. Ventral dististyle relatively small, fleshy, the rostral prolongation of moderate size, blackened, terminating in a small, chitinized, beak-like point; spines two, placed on the face of the prolongation at near mid-length, the inner spine a little longer and straighter than the slightly curved outer spine. Dorsal dististyle a gently curved rod that is narrowed at tip into a long spine. Ædeagus broad, trifid at apex. Ovipositor with the basal shields and valves fulvous-brown; tergal valves slender, gently upcurved, relatively small, but still much larger than in *whitei*.

Hab. Victoria.

Holotype, ♂, Ferntree Gully, April 15, 1928 (*F. E. Wilson*).

Allotopotype, ♀.

Paratype, ♀, Ringwood, May 5, 1928 (*F. E. Wilson*).

Type returned to Mr. Wilson.

Limonia dicksoniæ is generally similar to *L.* (*D.*) *whitei* (Alexander) of Victoria and Tasmania, but it is very distinct in the diagnostic features listed above. It likewise resembles *L.* (*D.*) *helmsi* (Skuse), but differs in the details of venation, as the long, gently arcuated *Rs*.

Limonia (*Dicranomyia*) *dorrigensis*, sp. n.

Belongs to the *liberta* (*tristis*) group; allied to *illingworthi*; size very small (wing, ♂, about 4 mm.); wings greyish, unmarked except for the stigma; male hypopygium with the gonapophyses very broad.

Male.—Length about 3·2 mm.; wing 4·1 mm.

Rostrum, palpi, and antennæ black; flagellar segments oval. Head dark grey.

Mesonotal præscutum yellowish grey, with three brown stripes; scutal lobes darkened; remainder of mesonotum more brownish grey. Pleura dark greyish brown. Halteres yellow, the knobs infuscated. Legs with the fore and middle coxæ extensively dark brown, the hind coxæ chiefly obscure yellow; trochanters reddish; remainder of legs brown, the tarsal segments passing into dark brown. Wings greyish, the oval stigma a little darker than the ground-colour; veins dark brown. Venation: Sc_1 ending about opposite the origin of *Rs*, the latter nearly three times the basal section of R_{4+5}; cell 1*st* M_2 elongate, longer than the veins issuing from it; *m–cu* more than one-half its length before the fork of *M*.

Abdominal tergites dark brown, the sternites more yellowish; hypopygium brownish yellow. Male hypopygium with the tergite transverse, the caudal margin evenly and convexly rounded, with a marginal series of setæ, including a median pair that are longer and stouter. Basistyle relatively small, the ventro-mesal lobe very stout, terminating in a dense brush of setæ; on face of style a small fingerlike lobe that is tufted with setæ that are considerably longer than the lobe itself; a small group of three or four strong setæ near the apical mesal portion of the basistyle. Dorsal dististyle a gently curved rod that is slightly expanded on outer half, thence gradually narrowed to a long apical spine. Ventral dististyle fleshy, including the broad rostral prolongation; the two rostral spines placed side by side, subequal in length, arising from low tubercles. Gonapophyses with the mesal apical lobe very broad, the outer margin weakly toothed, the lobe merging gradually with the main body of the apophysis.

Hab. New South Wales.

Holotype, ♂, Brooklana, Eastern Dorrigo, altitude about 2000 feet, February 10, 1929 (*W. Heron*).

Limonia dorrigensis is allied to *L.* (*D.*) *illingworthi* (Alexander), differing most evidently in the small size, wing-pattern, and structure of the male hypopygium, especially of the gonapophyses.

Limonia (*Dicranomyia*) *flavidella*, sp. n.

General coloration pale yellow; legs long and slender, the terminal tarsal segments darkened; wings pale yellow, the stigma vaguely darker; costal fringe relatively long and conspicuous; cell M_2 open by the atrophy of m.

Male.—Length about 5 mm.; wing 6 mm.

Rostrum and palpi pale yellow. Antennæ broken. Head ochreous-yellow.

Mesonotum and pleura uniformly reddish yellow, without markings. Halteres of moderate length only, pale yellow throughout. Legs long and slender, pale yellow, only the terminal tarsal segments infuscated; claws simple, except for a basal spine. Wings uniformly pale yellow, the stigma vaguely darker; veins darker yellow. Costal fringe relatively long and conspicuous. Venation: Sc short, Sc_1 ending opposite the origin of Rs, Sc_2 a short distance from its tip, Sc_1 alone about one-half the length of Rs; Rs about one-third to one-fourth longer than the basal section of R_{4+5}; cell M_2 open by the atrophy of m; m–cu at or shortly before the fork of M; distal section of Cu_1 a little shorter than m–cu.

Abdomen uniformly ochreous-yellow. Male hypopygium with the ninth tergite transverse, the caudal margin virtually straight across, each lateral angle with about a dozen setigerous punctures. Basistyle relatively short and stout, the ventro-mesal lobe large, conspicuously setiferous. Ventral dististyle large and fleshy, much larger than the basistyle, the rostral prolongation relatively slender, with two conspicuous spines; outer spine about three-fourths the length of the inner, placed a little more than one-half its length from the tip of the prolongation; spines placed close together. Dorsal dististyle a strongly curved hook, the long slender apex blackened. Gonapophyses very extensive, pale, the mesal apical angle curved to the obtuse tip. Ædeagus bifid at tip.

Hab. Victoria, New South Wales.

Holotype, ♂, Millgrove, Victoria, altitude about 1600–1700 feet, in a deeply shaded fern-gully, April 7, 1928 (*F. E. Wilson*).

Paratype, ♂, Eastern Dorrigo, New South Wales, altitude 2000–3000 feet, February 27, 1929 (*W. Heron*). "Beaten from tree-fern foliage, *Dicksonia antarctica*" (*F. E. Wilson*).

Type returned to Mr. Wilson.

Limonia (*Idioglochina*) *perkinsiana*, sp. n.

Allied to *tusitala*, Alexander; general coloration dark brownish grey; mesonotal præscutum brown, with four dark brown stripes; pleura dark brownish grey; legs dark brown, including the coxæ; wings with a strong dusky tinge; male hypopygium with the caudal margin of the ninth tergite bearing a small, deep, V-shaped median notch.

Male.—Length about 6 mm.; wing 7·5 mm.

Rostrum dark brown, nearly as long as the remainder of the head; palpi dark brown. Antennæ dark brown, the first segment more pruinose; flagellar segments strongly produced beneath, as in the *tusitala* group, the apical necks short and stout. Head pale reddish brown, sparsely pruinose, the median region of the vertex more infuscated.

Mesonotal præscutum with the interspaces brown, the disk with four dark brown stripes, the lateral and posterior portions of the sclerite dark greyish plumbeous; pseudosutural foveæ punctiform, dark brown; scutum light grey medially, each lobe with two dark brown areas; scutellum and postnotum light grey. Pleura dark brownish grey, the dorso-pleural membrane buffy. Halteres obscure yellow. Legs with the coxæ dark brown, pruinose, the apices restrictedly pale; remainder of legs dark brown, the femoral bases only a trifle brighter; claws with a series of about four teeth, the outermost longest. Wings with a strong dusky tinge, *Rs* and *Cu* more suffused with still darker brown; veins yellowish brown, some darker brown. Venation: *Sc* relatively long, the distance on costa between Sc_1 and origin of *Rs* about two-thirds the length of the latter; basal section of R_{4+5} about two-thirds *Rs*; R_{2+3} only gently arcuated; *m–cu* shortly beyond the fork of *M.*

Abdominal segments dark brown, the tergites vaguely more reddish brown medially at base; caudal margins of the segments very restrictedly pale; sternites obscure brownish yellow, darker laterally, the caudal margins narrowly pale; hypopygium more brightened. Male hypopygium with the caudal margin of the ninth tergite with a small but deep V-shaped median notch. Dorsal dististyle strongly curved, sickle-shaped, narrowed to the subacute apex. Ventral dististyle with the inner beak-like portion stout, the tip obtuse.

Hab. Queensland.

Holotype, ♂, Dunk Is., August 25, 1927 (*F. A. Perkins*).

I name this crane-fly in honour of the collector, Mr. F. A. Perkins.

Type in the University of Queensland.

Limonia perkinsiana is allied to *L.* (*I.*) *vilæ* (Edwards) and *L.* (*I.*) *novocaledonica*, Alexander, differing from both in the very dark colour and details of structure of the male hypopygium.

Eurhamphidia invenustipes, sp. n.

General coloration brownish grey; legs uniformly darkened; wings subhyaline, iridescent, the stigma and apex darkened.

Male.—Length about 6–6·3 mm.; wing 6·4–6·8 mm.

Rostrum approximately as long as the remainder of head, dark brown; palpi black. Antennæ short, brownish black, the first segment obscure yellow at base. Head brownish grey.

Pronotum dark brown. Mesonotal præscutum yellowish brown, with a narrow but conspicuous dark brown median stripe that does not extend to the suture; scutum pale brown, the centres of the lobes brownish black; scutellum and postnotum light brown. Pleura pale brown, pruinose, darkened dorsally; dorso-pleural membrane obscure buffy brown; sternopleurite darker brown. Halteres slender, dark brown, the base of the stem restrictedly obscure yellow. Legs long and slender; coxæ obscure yellow, the fore coxæ more infuscated; trochanters obscure yellow; femora brown; remainder of legs brown, without white markings. Wings highly iridescent, subhyaline; stigma elongate, dark brown; wing-apex narrowly darkened; veins dark brown. Venation: Sc_1 ending nearly opposite *r–m* or somewhat beyond it, Sc_2 not far from its tip; first section of *Rs* nearly twice the second; veins R_3 and R_{4+5} divergent apically; *m–cu* at near mid-length of cell 1*st* M_2, in approximate alignment with *r–m*.

Abdomen relatively long and slender, brownish black, the basal sternites obscure yellow.

Hab. West Australia.

Holotype, ♂, Donnybrook, August 29, 1926 (*E. W. Ferguson*).

Paratype, ♂, Pemberton, August 28, 1926 (*E. W. Ferguson*).

Type in the Macleay Collection.

Eurhamphidia invenustipes is entirely different from *E. niveitarsis* (Skuse), the only other described Australian species.

XI.—*Descriptions and Records of Bees.*—CXXII.

By T. D. A. Cockerell, University of Colorado.

Bombus discrepans, Pendlebury.

3 ♂, Koo Luang, Nakawn Sritamarat, Siam, April 30, 1928 (*Kerr*).

The genitalia, which differ considerably from those of any species known to me, were not described by Pendlebury. Spatha strap-shaped, parallel-sided, acutely pointed at apex; sagitta stout, very obliquely truncate apically, with the lower (outer) corner produced into a sort of short beak; stripes very broad at base, apically broadly truncate, for the attachment of the squama; squama black, somewhat U-shaped, with very thick base, outer arm broadly attached to stipes, but not projecting, inner much shorter, and pointed; volsella extending finger-like far beyond squama, the apex obtuse, somewhat broadened, its inner margin concave; stiff bristles project from beneath the apical portion.

The specimens were taken at an altitude of 1400 to 1600 m.

In its general appearance this bee is exactly like *B. ignitus*, Sm., from Japan.

Trigona ambusta, Cockerell.

Siam; Koh Po, Pattani, April 5; many from nest in hollow tree (*Kerr*).

The mesothorax and tegulæ are considerably darker than in the type. New to Siam.

Trigona bakeri, Cockerell.

Siam; Tung Nui, Satul, at flowers of *Melastoma malabaricum*, March 19 (*A. F. G. Kerr*).

The red spots at extreme base of antennæ are very obscure. New to Siam.

Trigona biroi, Friese.

Taken by Dr. Kerr at the same time, place, and flowers as *T. bakeri*. New to Siam; it is common in the Philippine Is. The abdomen is perfectly black.

Trigona atomella, Cockerell.

Siam; Chun Het, Trang (*Kerr*).

"Taken on my own hands, April 15."

Trigona heideri, Friese.

British Guiana; Amatuk, May 24 (*J. Ogilvie*).

Trigona longipes, Smith.

British Guiana; Amatuk, Kangaruma, and Tumatumari (*J. Ogilvie*).

Trigona clavipes (Fabricius).

British Guiana; Rockstone, June 2 (*A. Mackie*).

Melipona interrupta oblitescens, Cockerell.

British Guiana; Kaieteur, May 27 (*A. Mackie*).

Melipona fasciata barticensis, Cockerell.

British Guiana; Kaieteur, May 27 (*A. Mackie*).

Augochlora (*Pseudaugochloropsis*) *ogilviei*, sp. n.

♀.—Length about or nearly 7 mm., anterior wing 5·5 mm. Robust, very bright yellowish green, shining, the abdominal tergites very broadly margined with black; hair of head and thorax scanty, dull white, abundant on sides of face; scutellum with long black hairs, and an admixture of short black hairs on mesothorax; mandibles reddened apically; face broad; clypeus black except upper margin; supraclypeal area black; middle of face elevated, forming an obtuse ridge; front shining, with a strong median groove; ocelli rather large; flagellum dull rufous beneath except basally; angles of prothorax obtuse; mesothorax highly polished, appearing impunctate under a lens, but the microscope shows minute piliferous punctures; scutellum polished like mesothorax, and also the large area of metathorax, which has no radiating plicæ, but under the microscope shows an excessively fine transverse lineolation, tending toward reticulation; tegulæ dark reddish. Wings dusky, nervures and stigma dark brown; second cubital cell extremely high and narrow; first recurrent nervure meeting second intercubitus. Legs black, with pale hair, small joints of tarsi rufescent, anterior legs obscurely rufescent in front; hind spur with five long dark sharp spines. Underside of abdomen obscurely reddish.

Five from Rockstone, British Guiana, June 2 (*J. Ogilvie*, *A. Mackie*).

In Vachal's table this runs to *A. elachion* (Vachal), from Honduras, but differs at once in the sculpture and the non-metallic legs. It is a distinct and easily recognized species.

Augochlora phanerorhina, sp. n.

♂.—Length 7·5–8·5 mm., anterior wing 5 mm.

Very bright emerald-green, the hind part of thorax more yellowish green, hind margins of abdominal tergites very broadly black; hair of head and thorax extremely scanty, pure white on cheeks, but vertex, scutellum, and post-scutellum with dark plumose hairs; eyes deeply emarginate; face narrow, clypeal region strongly produced, forming a thick snout, the clypeus convex, polished, with very strong close punctures, the apical margin narrowly black; labrum and mandibles reddish; supraclypeal area densely punctured; front dull; flagellum short for a male, obscurely reddened beneath; mesothorax shining, strongly and closely punctured, at each side anteriorly dull from the density of the punctures; scutellum strongly punctured; angles of prothorax very prominent and sharp; area of metathorax shining, with strong radiating plicæ, but no well-defined polished margin, its width (antero-posteriorly) in middle a little less than that of the large postscutellum, the hind margins of both angulate; tegulæ very dark reddish brown. Wings dusky hyaline, the rather small stigma sepia, nervures dark brown; second cubital cell rather narrow, especially above; first recurrent nervure meeting second intercubitus. Legs largely black, with pale hair, but anterior femora behind, middle femora beneath, and hind coxæ bright green, anterior tibiæ ferruginous in front, tarsi more or less reddish. Abdomen shining, with sericeous white tomentum; venter black, not modified, except that the margin of the second sternite is obtusely angulate in middle.

British Guiana; type and one other from Amatuk, May 24 (*J. Ogilvie*); one from Waratuk, May 24 (*J. Ogilvie*).

Very near to *A. esox*, Vachal, but distinguished by the black margin of clypeus. Probably Vachal's *A. esox* was composite, and the specimen cited from British Guiana may have been this species. I will designate Cuzco, Peru, as the type-locality, as Peru was the only country from which Vachal had both sexes of the typical form. In Schrottky's table of "Oxystoglossæ" with hind margins of tergites black, our insect runs to the couplet including *A. iheringi*, Ckll., and *A. feronia*, Smith, but it is not very close to these.

Augochlora (*Augochloropsis*) *cataractæ*, sp. n.

♂.—Length nearly 10 mm., anterior wing 7 mm.

Bright emerald-green, the convex shining supraclypeal area blue-green, abruptly contrasting with the golden suffusion of sides of face; abdomen rather bluish green, with the depressed hind margin of second tergite (about twice as long as that of first) golden green; tegulæ large, entirely green; legs green as far as the basal part of basitarsi (more than half of hind basitarsi), beyond that black, the apical joint of front legs rufescent; hair of head and thorax tinged with fulvous, but white on cheeks and under side of thorax; an admixture of dark hairs on head and thorax above; head broad, orbits very strongly converging below; clypeus convex, very coarsely and densely rugoso-punctate, the apical margin very narrowly black; mandibles (which are simple) and labrum black; process of labrum very broadly and deeply emarginate; tongue dagger-like, not very long; antennæ black; angles of prothorax very broad, not prominent; mesothorax very densely and coarsely rugoso-punctate; scutellum also roughened, but anteriorly shining, in contrast with the adjacent mesothorax; area of metathorax smooth and shining, with very delicate weak radiating plicæ at sides; metathorax behind enclosure rough. Wings hyaline; stigma small, pale greyish brown; second cubital cell higher than broad; first recurrent nervure meeting second intercubitus, a little on the outer side. Abdomen shining, but finely rugulose, first two tergites regularly vibrissate, the bristles dark brown; tergites beyond the first with a thin clothing of black hairs; apex with at each side a tuft of very long reddish hairs; venter with the first three segments bright green with black margins, fourth brownish black with two green patches.

Kaieteur, British Guiana, May 27, 1929 (*Alice Mackie*).

The specific name recalls the falls, which have a height of 800 feet. In Vachal's table this runs near to *A. rudis* (Vachal), and must be closely allied, differing by the mainly green basitarsi and the measurements (wing 9 mm. in *A. rudis*). In Schrottky's Brazilian table it runs to *A. electra*, Sm., but that has yellow tarsi. It is somewhat allied to the differently coloured *A. heterochroa*, Ckll.

Augochlora (*Augochloropsis*) *semitoralis*, sp. n.

♀ (type).—Length about 6 mm., anterior wing 5·3 mm.

Robust, brilliant shining emerald-green, more or less golden at base of antennæ and along orbits, golden at extreme sides of base of area of metathorax and along hind margin of first tergite; or the inner orbital margins may be without golden, or the region near the base of antennæ may show coppery red; femora green, the hind femora very dark brown, not metallic, posteriorly; tarsi very dark brown, not at all metallic, except the hind basitarsi slightly at base in front; hair of head and thorax very scanty, pale, with an admixture of dark hairs dorsally; hind tarsi with copious pale ferruginous hair on inner side; vibrissæ (same in both sexes) weak and rather irregular, the bristles tinged with orange; head broad, orbits strongly converging below; apical middle (but not sides) of clypeus broadly black; labrum and the bidentate mandibles black; a brilliant green spot at base of mandibles; antennæ black; prothorax laterally rounded, not angulate; disc of mesothorax brilliantly shining, with well-separated punctures, but sides extremely densely punctured; scutellum shining, with well-separated punctures; area of metathorax with a narrow curved channel, regularly crossed by strong plicæ, the broad rounded margin highly polished; tegulæ green basally, dark red outwardly, the whole effect very dark. Wings hyaline, faintly dusky; stigma dilute greyish brown; nervures fuscous, the costal nervure dark brown; second cubital cell broad, not far from square; first recurrent nervure meeting second intercubitus or going slightly beyond. Abdomen broad, shining, the hind margins of tergites with a slight effect of thin hair-bands. Hind spur with seven extremely long slender black spines, tipped with reddish.

♂.—Similar, except for the usual sexual differences; clypeus prominent, with a broad dull white apical band; labrum and mandibles rufous, the extreme base of mandibles green; antennæ black, but the third joint somewhat swollen and red (compare the much larger *A. callichroa*, Ckll.); legs green, with knees, tibiæ obscurely at extreme apex, and the tarsi light ferruginous; venter of abdomen not modified, the first three sternites green.

5 ♀, Amatuk, British Guiana, May 24 (*J. Ogilvie*); 1 ♂, Kaieteur, May 26 (*A. Mackie*).

This little bee is very close to *A. toralis*, Vachal, but appears to differ, especially by the dark tegulæ and costal nervure of the female. Schrottky states that *A. toralis* is a synonym of *A. calypso*, Sm., and while our species is very close to *A. calypso*, it is certainly distinct by the orbits not edged with blue, the vibrissæ not conspicuous, and the wings not yellowish. *A. toralis* is said to range from Mexico to Bahia and Pará in Brazil, and it is very likely that the series is composite. Its spur is not described by Vachal. Perhaps the Brazilian specimens were *A. calypso*, and those from British Guiana *A. semitoralis*. It is greatly to be desired that someone having access to Vachal's collection in Paris should designate holotypes and type-localities, and inform us when the series contains a mixture of species.

Halictus potaroënsis, sp. n.

♀ (type).—Length fully 5 mm., anterior wing 4 mm.

Head and thorax nearly black, but with a perceptible metallic tint, the upper part of clypeus and sides of face dark green, supraclypeal area rosy red, cheeks green, vertex dark steel-blue, mesothorax and scutellum obscurely bluish, the scutellum slightly purplish, metathorax and pleura dark green; abdomen black, with the hind margins of the tergites rufescent; hair very scanty. Head rather oblong, with the clypeus prominent; mandibles dark, faintly reddened about the middle; clypeus shining, the apical portion black; inner orbits concave; front dull, very densely and minutely punctured (not striate); prothoracic angles prominent, rectangular; tubercles prominent, pointed; mesothorax shining, the surface microscopically tessellate, with scattered very minute punctures; scutellum moderately shining; area of metathorax large, the apical portion smooth and shining, the base minutely plicatulate; tegulæ very dark rufous, sparsely and weakly but evidently punctured (same in both sexes). Wings brownish hyaline, stigma large, very dilute brown, nervures fuscous, outer recurrent and intercubitus very weak; second cubital cell broader below than above, its lower side strongly oblique, receiving recurrent nervure a short distance before end. Legs black, with the tarsi and base of hind tibiæ dull ferruginous; hind spur with three long spines. Abdomen shining, thinly hairy, with a tendency to bands at sides of tergites 2 to 4.

♂.—Similar, except for the sexual characters; clypeus with a broad apical rufo-testaceous band; labrum red; mandibles mainly reddish; mesothorax shining dark green; hind knees, apex of their tibiæ, and the tarsi pale testaceous; antennæ only moderately long for a male, the flagellum pale testaceous or clay-colour beneath.

Kaieteur, British Guiana, May 27, 1929 (*Alice Mackie*).

Belongs to the subgenus *Chloralictus*, and is related to a series of Neotropical forms which are doubtless far more numerous than the present records show. *H. semiviridis*, Friese, from Bermuda, is smaller and less robust, with shorter face. *H. exiguiformis*, Ellis, from Guayaquil, has a much shorter and broader head and olive-green mesothorax. I do not find any species near enough to cause confusion.

Sphecodes biroi mariæ, subsp. n.

♂.—Length about 7 mm., anterior wing 6·3 mm.

General characters of *S. biroi*, Friese, with very broad face, covered with white hair, hairy eyes, no pubescent bands on flagellar joints, flagellum strongly nodose beneath; wings brownish, pale basally; first three abdominal tergites mainly red. Mandibles red in middle; flagellum entirely dark; tegulæ very dark, obscurely reddish externally; hind wings with eight hooks; first tergite with a broad hemispherical black patch, second blackened in middle, especially apically, third red only at base; tarsi brownish black, red only at apex.

Compared with the Philippine Is. *S. latifrons*, Ckll., it is seen to be very closely allied, but larger and more robust, with dark tegulæ, and base of metathorax more densely sculptured. The second and third tergites are more strongly and closely punctured than in *S. latifrons*. *S. abnormis*, Perkins, has testaceous tarsi and presents a number of other small differences. *S. dutti*, Blüthg., is also evidently different.

Siam ; Nan, Jan. 8, 1928 (*Cockerell*).

Named after Dr. Mary Collier, who collected many insects at Nan. The group of *S. biroi* cannot be fully elucidated at present. Blüthgen (1927) combines all the different forms (with a query in respect to *S. dutti*) under the specific name *S. biroi*, originally based on an insect from New Guinea. This seems to be going too far, though it is useful to call attention to the close alliance. I treat the Siamese insect as a subspecies, but suppose that eventually a series of closely allied species will be recognized.

Habropoda sutepensis, Cockerell.

Described from the male. The female, from the same locality (Doi Sutep, Siam), is similar, but larger and more robust, the dense hair of the abdomen very red. Clypeus convex, the upper third in middle with a shining keel, from the lower end of which starts a creamy-white vertical band, rapidly broadening below to form a broadly triangular pale area ; labrum reddish ; mandibles with more than the basal half pale rufous ; malar space well developed ; outer side of hind tibiæ with rich copper-red hair; hind basitarsi with black hair. The cheeks below have long pure white hair.

Osmia pseudamala, Cockerell.

Described from the male. Mr. R. Betensky has found both sexes at White Rocks, Boulder, Colorado, nesting in an old log. The female is somewhat over 10 mm. long, robust, steel-blue, with the front, vertex, occiput, mesothorax, and scutellum green ; mandibles tridentate ; hair of head and thorax above pale fulvous-tinted, mixed with black ; tegulæ half green. Legs black, hind femora green in front; ventral scopa black. In my table (Univ. of Colo. Studies, 1928) it runs nearest to *O. albolateralis*, Ckll., though the mesopleura has black hair on the upper posterior part, or may have it mostly black, in which case it runs to *O. malina*, Ckll. *O. albolateralis* has much longer and more conspicuous black hair on clypeus. *O. malina* is 9 mm. long, with hair of scutellum mainly black, and several other differences. Miss Sandhouse points out that the genitalia of *O. pseudamala* are highly distinctive, as she will describe in her revision.

XII.—*Three new Species of the Genus* Helotrephes* (*Hemiptera-Heteroptera*). By W. E. China.

The following descriptions are based on material sent for determination by Mr. G. L. R. Hancock, Assistant Government Entomologist in Uganda, and by Prof. H. B. Hungerford, of Kansas University, to whom I am indebted for the opportunity of examining the Helotrephid material discovered by him in the Amsterdam Museum.

In not a single case was a species of *Helotrephes* known from both sexes, and in only one case (*H. bouvieri* ♂) had it been possible to make dissections. Consequently the detailed structure of the female genitalia has hitherto remained unknown; so that it was extremely interesting to receive, through Prof. Hungerford, a series of specimens of both sexes. Owing, however, to paucity of material in the described species and to the absence of knowledge of the limits of variation, and considering the fact that each species probably exists in two structurally different forms (winged and wingless), it has been very difficult to decide on the identity of the Sumatran species. After much consideration and hesitation it has been decided to describe them both as new.

Helotrephes angulatus, sp. n. (Figs. 1 *a–g*; fig. 3 *d*.)

Colour (♀).—Dorsal surface pale sordid yellow marked with brownish black. Head brownish black, with an irregular-edged three-lobed border and some obscure markings on the disc and along base above the suture, pale sordid yellow (fig. 1 *a*); eyes and rostrum dark brown. Pronotum pale sordid yellow, the anterior margin along the suture brownish black, the posterior margin of this dark band strongly bisinuate, its lateral margins speckled, not reaching the lateral margins of the pronotum; posterior half of pronotum speckled with dark brown. Scutellum pale sordid yellow, moderately densely speckled with dark brown, with a large pale yellow spot at each side of base and a third in middle of base. Hemielytra pale sordid yellow, sparsely speckled with brown, the clavus and clavulus mottled with dark brown, a spot on corium at apex of clavus and the extreme apical margin of corium along interlocking device dark brown. Legs pale yellow, the coxæ, trochanters, bases of hind femora, and extreme apices of tibiæ and tarsi infuscate. Sternum and venter pale brown.

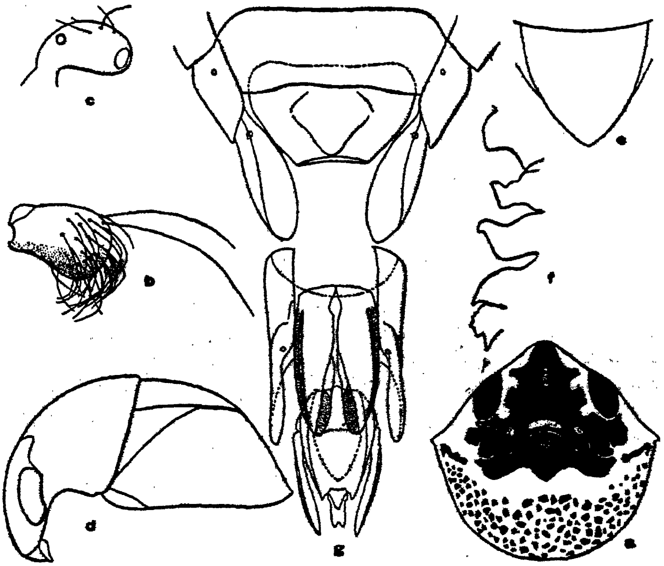
Structure (♀).—Seen in profile (fig. 1 *d*) the lateral margin of pronotum and lateral margin of head with a respective inclination of about 110°, the actual angle broadly rounded. Rostrum moderately long, extending just to the intermediate coxæ. First antennal segment (fig. 1 *c*) with its axis at right angles with the point of insertion, otherwise more or less cylindrical, with three or four scattered bristles on exposed surface, and a curious circular

---

* For monograph of this genus, see 'Eos,' iv. pt. 2, pp. 129–172.

organ towards its base similar to that in *Idiocoris lithophilus*; second segment slightly longer than first, wider at apex than base, rounded apically, distinctly flattened, the outer surface covered with long, strongly-curved, flattened hairs, apex with two long filiform divergent bristles (fig. 1 *b*). Pronotum with the lateral margins distinctly carinate, the carina ending abruptly before the humeral angle to form an angulated tooth (fig. 3 *d*). Scutellum about as long as broad (fig. 1 *e*). Hemielytra with distinct claval suture, the clavulus well marked; costal margin of right-hand hemielytron devoid of a lateral lobe. Wings present, whitish hyaline, similar to those in *H. bouvieri*. Median prosternal keel strongly elevated, semihyaline, rounded anteriorly, acute-angled posteriorly, the posterior edge more or less perpendicular. Mesosternal carina strongly elevated, hyaline, wide at base, narrowed in middle, truncate at apex, which is produced anteriorly into a tooth. Metasternal carina broad, the anterior edge concave, the posterior edge short and straight, and the apex obliquely truncate, with anterior angle curved outwards and posteriorly (fig. 1 *f*). Front legs longer than the middle legs, the coxæ finely tuberculate and

Fig. 1.



Helotrephes angulatus, sp. n., ♀.

a, diagrammatic dorsal view of cephalonotum, to show colour-markings; *b*, second antennal segment; *c*, first antennal segment; *d*, profile view; *e*, scutellum; *f*, lateral view of median, sternal, and ventral carinæ; *g*, female genital segments.

covered on outer surface with long depressed hairs; femur thickest at base and tapering to apex, slightly longer than tibia (55:50), armed along inner side with longitudinal rows of short spines and longer bristles, the latter longer towards base; armed along outer side with a row of long semidepressed bristles, and a pair of long divergent bristles at base; tibia also armed along inner side with rows of short spines, bristles, and pectinate bristles; tarsus less than half the length of tibia (18:51), with inner rows of bristles and the usual apical structure; claws about one-third the length of tarsus. Middle legs similar to front legs but shorter, the femur distinctly longer than tibia (55:43), the bristles along its inner side longer towards base, those along outer side much shorter, the upper surface with a number of scattered short spines; tibial bristles longer, especially towards apex; tarsus nearly half the length of tibia, the claws about one-fourth the length of tarsus. Hind legs with femur shorter than tibia (59:72), inner side with two rows of short bristles, longest on basal half; tibiæ and tarsi with the usual long swimming-hairs and bristles; tarsal segments together nearly two-thirds the length of tibia, the second segment much shorter than first (19:25); claws about one-third the length of the first segment. Median keel of second abdominal sternite, seen in profile, strongly convex anteriorly and concave posteriorly, its apex acute and directed posteriorly, median keel of third abdominal sternite with a broad serrated basal lobe and a small posteriorly directed spur-like apical lobe (fig. 1 *f*); seventh sternite short, narrowed apically, the posterior margin concave, disc with a raised median triangular lobe; pleurites of seventh segment broad and concavely foliate; female genital segments (fig. 1 *g*) much narrower and more elongate than in *Tiphotrephes*, *Limnotrephes*, *Idiocoris*, or *Paskia*, otherwise similar in general plan, the eighth sternite split into two elongate lobes, with their inner apical extremities deflexed to form thickened flap-like appendices, pleural processes of eighth segment elongate, concave; ninth tergite with two elongate lobe-like lateral processes similar to the pleural processes of the seventh and eighth segments, and with a triangular anal flap representing the tenth segment (?); ninth sternite represented by a semitubular sclerite, the apex strongly emarginate, with the apical angles acute. An elongate style-like organ, with its apex bifid and with a small triangular lobe placed ventrally at its base, possibly represents the eleventh segment.

Total length 2·83 mm. Other measurements, see *H. hancocki*, sp. n.

Habitat.—Sumatra's O. K., Medan, 20 m.

Type, 1 ♀, 13. ix. 1921; paratypes, 1 ♀, 13. ix. 1921; 1 ♀, 3. x. 1921. J. B. Corporaal (Amsterdam Museum).

Allied to the Sumatran species *H. martini*, Kirk., which it resembles in general shape of the sternal and abdominal carinæ, shape of scutellum, and relative length of cephalonotum, but differs in the presence of the strongly-developed lateral pronotal carinæ with their angulate posterior extremities, absence of a lateral costal lobe on right-hand hemielytron of female, in the relative length of the hind tarsal segments, and in the presence of wings and a distinct claval suture.

The possibility of this species being the winged form of *H. martini* has been considered, but other details have been thought not sufficiently identical.

Helotrephes corporaali, sp. n. (Figs. 2 *a–g* ; figs. 3 *a–c*.)

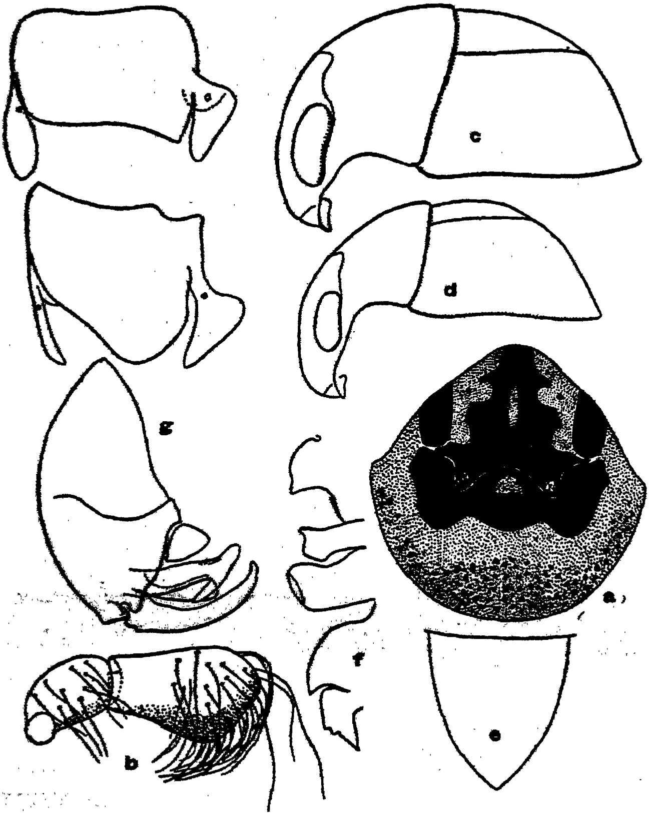
Colour (♂).—Dorsal surface greyish yellow marked with dark brown. Head dark brown, the anterior lateral areas in front of eyes, a large spot on middle of inner margin of eye, a small spot posteriorly on inner margin of eye, and an obscure narrow spot in middle of anterior disc fulvous-yellow; eyes and rostrum dark brown. Pronotum greyish yellow, the anterior margin along the suture dark brown, the posterior margin of this dark band bisinuate, its edges speckled and not reaching lateral margins of pronotum; posterior half of pronotum speckled with dark brown. Scutellum pale sordid yellow densely covered with the usual subchitinous brown speckling, and a dark brown band along basal margin which extends, less intensely, on to middle of disc in the form of a triangular mark. Hemielytra similar to scutellum, with a few indistinct brown marks over claval area and towards apex of scutellum brown. Legs fulvous-yellow, the coxæ, trochanters, base of hind femur, apices of front and middle tibiæ and tarsi moderately infuscate. Sternum and venter pale greyish brown.

♀.—Similar to ♂, but pale markings on head more or less confluent, forming a fulvous band along lateral margin of head and inner margin of eye, with its inner border irregular in outline; an obscure, almost obsolete, fulvous-brown longitudinal stripe extends down middle of disc; pronotum as in ♂, but with a light fulvous spot in middle of brown anterior band, just below the middle of the suture; scutellum without the triangular infuscation, but with a pair of transverse dark brown spots along posterior margin of anterior brown band.

Structure (♂ ♀).—Seen in profile (figs. 2 *c* & *d*), the lateral margin of pronotum and lateral margin of head with a respective inclination of about 130° (♂) or 110° (♀), the actual angle broadly rounded. Rostrum moderately long, extending to intermediate coxæ. Antenna (fig. 2 *b*) very similar to that in *H. bouvieri*, with the second segment trapezoidal but rather less broad at the apex and longer in proportion to its width (29:16). Pronotal lateral carina percurrent, not ending abruptly as in *H. angulatus* (fig. 3 *b*). Scutellum (fig. 2 *e*) slightly longer than broad at base (33:30 ♂, 40:37 ♀). Hemielytra without claval suture or clavulus, without a lateral costal lobe in ♀, wings absent or rudimentary. Median prosternal carina seen from side similar to that in *H. angulatus*, but with the posterior angle more acute. Mesosternal carina narrow, parallel-sided at base, slightly dilated towards apex, which is truncate, the anterior angle pointed, the posterior angle rounded. Metasternal carina broad, the anterior edge concave, the posterior edge straight, and the apex truncate; the apical extremity very thin in middle (fig. 2 *f*). Armature of legs similar to that in *H. angulatus*; relative measurements in ♂:—

	Femur.	Tibia.	Tarsus.	Claws.
Front leg	58	52	17	5
Middle leg	54	40	19	7
Hind leg	55	64	22 + 18	8

Fig. 2.



Helotrephes corporaali, sp. n.

a, diagrammatic dorsal view of cephalonotum ♀, to show colour-markings; *b*, antenna of ♂; *c*, profile view of ♀; *d*, profile view of ♂; *e*, scutellum; *f*, lateral view of median, sternal, and ventral carinæ of ♂; *g*, male genital segments.

Median keels of second and third abdominal sternites, seen in profile, similar to those in *H. bouvieri*, but that of the third more sinuate along its edge (fig. 2 *f*); seventh sternite in ♀ as in *H.*

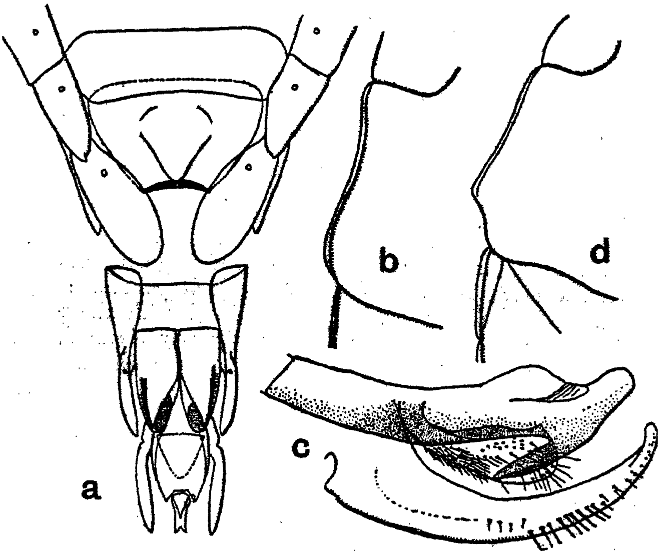
angulatus, the pleurites very broad and foliate. Genital segments in ♀ (fig. 3 *a*) very similar to those in *H. angulatus*, but the lobes of the eighth sternite much shorter. Genital segments in ♂ (fig. 2 *g*) very similar to those in *H. bouvieri*, but some slight differences in the shape of the pleurites; ventral paramere more curved at its apex, dorsal paramere more angular at its anterior apical angle, posteriorly directed barb of ædeagus relatively longer (fig. 3 *c*).

Total length, ♂ 2·67 mm., ♀ 3 mm. Other measurements, see *H. hancocki*, sp. n.

Habitat.—Sumatra's O. K., Medan, 20 m.

Type, 1 ♂, 3. x. 1921; paratypes, 2 ♂ ♂, 26. ix. 1921, and 2 ♂ ♂, 3. x. 1921, 1 ♀, 22. ix. 1921, 1 ♀, 26. ix. 1921, and 2 ♀ ♀, 3. x. 1921; also 2 larvæ, 13. ix. 1921.

Fig. 3.



Helotrephes corporaali, sp. n.—*a*, female genital segments; *b*, lateral margin of pronotum; *c*, male genitalia, showing hammer-headed ædeagus, long ventral paramere, and short dorsal paramere.

Helotrephes angulatus, sp. n.—*d*, lateral margin of pronotum, to show abbreviated carina.

Allied to *H. bouvieri* ♂ in the shape of antennæ, structure of ♂ genitalia, and in disproportionate lengths of hind tarsal segments. Differs, however, in much smaller size, shorter scutellum, and in the relative proportions of measurements CD & AD.

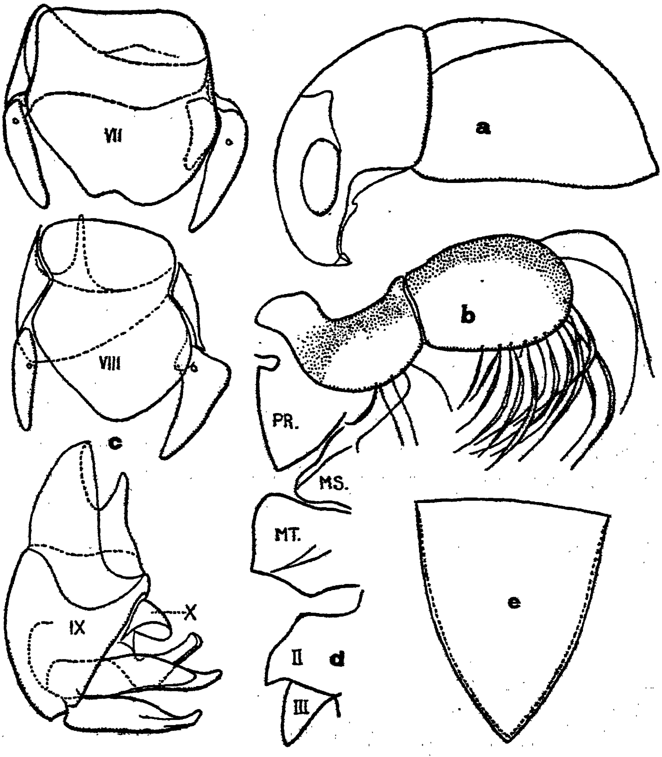
It is just possible that this species may be identical with *H. semiglobosus*, the length of which is given by Stål as 3 mm.

Helotrephes hancocki, sp. n. (Figs. 4 *a–e*.)

Colour (♂).—Very dark dull ferruginous-brown; eyes darker, almost black; a distinct border round eyes, a large obscure spot on each side of apex of head, a short longitudinal stripe on disc of cephalonotum just below centre of suture, posterior margin of pronotum, lateral pronotal plate, a small spot in middle of base of scutellum, a large spot on each side touching lateral margin near base of scutellum, a large obscure spot in corner of clavus between base of scutellum and posterior margin of pronotum, and a smaller spot in middle of base of corium very pale sordid yellow; scutellum paler towards extreme apex, which is obscurely pale sordid yellow; rostrum, apices of tarsi, and claws ferruginous-brown; legs brownish yellow, coxæ and basal third of hind femora dark brown.

Structure (♂).—Seen in profile (fig. 4 *a*) the lateral margin of pronotum and lateral margin of head with a respective inclination of about 110°. Rostrum moderately long, extending slightly beyond apices of anterior coxæ. Antenna (fig. 4 *b*) with the first segment curved almost at a right angle with its basal third, which is distinctly narrowed; apical half with a few long hairs; second segment longer than first, rounded and more broad apically, flattened dorso-ventrally, apical half covered with long, curved, flattened hairs, two long apical hairs less conspicuous than in *H. bouvieri* and *H. martini*; the segments in close contact, with apparently no stalk-like connection between them as in other species. Scutellum (fig. 4 *e*) much longer than broad at base (24 : 20), its apex angular. Hemielytra similar to those in *H. bouvieri*, regularly shallowly punctate, a short pale hair arising from each puncture; claval suture absent, the clavus and clavulus fused with the corium. Wings absent. Median prosternal keel strongly elevated, semi-hyaline in profile, more or less broadly lanceolate, directed posteriorly (fig. 4 *d*); mesosternal keel feebly elevated; metasternal keel strongly elevated, seen in profile very broad, anteriorly rounded, and posteriorly right-angled. Front legs longer than middle legs, the coxæ finely tuberculate and with long depressed hairs; femur thickest towards base, slightly longer than tibia, armed along inner side with longitudinal rows of short spines and longer bristles, and along outer side with a row of long semidepressed bristles, a hair at the base very long; tibiæ also armed along inner side with rows of spines, bristles, and pectinate bristles; tarsi about half the length of tibiæ, with inner rows of bristles, and with apical structure similar to that in *H. bouvieri*; claws about one-third the length of tarsus. Middle legs similar to front legs, but shorter, the femur distinctly longer than tibia (40 : 30), with the inner rows of spines and bristles becoming much longer towards base and with a number of scattered very short spines on upper surface; tibial spines longer, tarsus more than half the length of tibia (17 : 30), claws less than one-third length of tarsus; hind legs with the femur shorter than tibia (40 : 46), apical half of inside of femur with two rows of very short spines and no bristles, the femur suddenly constricted in the middle of the inner side; tibiæ and tarsi with the usual long swimming-hairs and bristles; tarsal segments equal in length, the claws about half the length of a single segment. Abdomen with the median basal keels of second and third sternites (fig. 4*c*) similar to those in *H. bouvieri*, but the left-hand pleural process of the seventh segment comparatively narrow, as in *Tiphotrephes*, not dilated and triangular, and the posterior margin of the seventh ventrite strongly posteriorly curved, with a concave apical sinuation, not truncate, as in *H. bouvieri*. Ventral paramere comparatively straight, broad, and parallel-sided for basal half, then more or less suddenly narrowed and ridged, the apex obliquely truncate. Dorsal paramere bent almost at a right angle in the middle, where it is very broad, but narrowed basally and apically, the apex shortly broadened and truncate. Ædeagus tubular, somewhat sinuate, gradually narrowed to a pointed apex, not hammer-headed as in *H. bouvieri* (fig. 4*c*).

Fig. 4.



Helotrephes hancocki, sp. n., ♂.
a, profile view; *b*, antenna; *c*, genital segments; *d*, median, sternal, and ventral carinæ; *e*, scutellum.

Total length 2 mm. Other measurements arranged as in "Monograph of Helotrephinæ" (for which see 'Eos,' iv. pt. 2, pp. 135–137).

Habitat.—Uganda, Kampala, Lake Victoria.

Type, ♂; paratypes, 2 ♂; and 1 larva, 30. vi. 1929 (*G. L. R. Hancock*).

Distinguished at once from all other species of *Helotrephes* by small size. Allied to *H. hungerfordi* from French Equatorial Africa, but much smaller, without a claval suture, and with the prosternal carina with its posterior angle acute. There is a remote possibility that this species may eventually prove to be the wingless male of *H. hungerfordi*. The structure of the ædeagus in *H. hancocki* is apparently not typical of that in *Helotrephes*, but until males of more species of the genus are known it is impossible to decide if this character is of subgeneric importance.

The structure of the female genitalia in the Helotrephinæ, while similar in general plan to that in the Idiocorinæ, differs in the more elongate form and in the presence of a semitubular apical abdominal segment, which may represent either the tenth or eleventh segment.

GEOLOGICAL SOCIETY.

October 23rd, 1929.—Prof. J. W. Gregory, LL.D., D.Sc., F.R.S., President, in the Chair.

The following communication was read:—

'The *Petalocrinus* Limestone Horizon at Woolhope (Herefordshire).' By Roy Woodhouse Pocock, M.Sc., F.G.S.

Upper Llandovery sandstones surmounted by Woolhope Limestone beds form the core of the Silurian anticline of Woolhope. These two groups are separated by a thickness of some 20 feet of Transition Shales with thin bands of limestone. One of these limestone-bands, averaging an inch in thickness, occurs in the Transition Beds about 5 feet from their summit, and is composed mainly of the remains of the crinoid *Petalocrinus*, which has been recorded from Sweden and North America, but has not hitherto been found in Britain.

The most striking peculiarity of the crinoid is the fusion of the arms into five solid arm-fans or petals, which radiate from the dorsal cup. The arm-fans are usually found detached in the limestone, throughout which they are profusely scattered.

A bed of large tabulate corals on which the *Petalocrinus* Band rests is found in this association throughout the outcrop. The combined thickness of the crinoid and coral-beds varies between 3 and 6 inches.

Llandovery rather than Wenlock affinities are indicated by the fauna of the Transition Beds.

Detailed mapping of the outcrop of the limestone-band has revealed interesting and unexpected features in the structure of the area, which appears to have been subjected to pressure, mainly along a north-west and south-east axis, developing thrust-faulting approximately at right angles to that axis.

Evidence is advanced in favour of a late Coal-Measure age for the principal movements that gave rise to the anticline.

At May Hill and at Malvern the *Petalocrinus* Limestone, with its associated coral-bed, has been detected at the same horizon as at Woolhope.

November 6th, 1929.—Prof. J. W. Gregory, LL.D., D.Sc., F.R.S., President, in the Chair.

The following communication was read:—

'Fossil Insects of the South Wales Coalfield.' By Herbert Bolton, D.Sc., F.R.S.E., F.G.S.

The Author describes a collection of fossil wings from the South Wales Coal Measures numbering nineteen specimens. Several are too fragmentary for determination of genus or species, or both; the remainder are referable to the Palæodictyoptera and Blattoidea.

To the first order two new species are ascribed, and to the latter ten species, the remainder being Blattoid wing-fragments too incomplete for determination.

The Palæodictyopteron wings are referred to the genus *Lithosialis*, hitherto only known from the Coal Measures of Coalbrookdale (Shropshire).

The Blattoid species are referable to the family Archimylacridæ, three species; and the tribe Hemimylacridia, seven species. The stratigraphical range of insect-remains is from the Triquart Seam of Tumble (South Wales) of Westphalian age, through the Staffordian upwards to the Penyscallen Seam of Gorseinon (Glamorgan) in the Radstockian.

Palæontologically, the insect-fauna of South Wales now shows relationships with the insect-faunas of the Midland and Northern coalfields, and a close approximation to forms already known from the Coal Measures of Coalbrookdale (Shropshire), the Forest of Dean, and those of Kent, while several of the Hemimylacridian forms are identical with species described by Prof. Pierre Pruvost from the Coal Measures of Pas-de-Calais (Northern France).

The South Wales Coal Measure insect-fauna thus approaches more nearly to the Pas-de-Calais facies than to that of any British coalfield.

The occurrence of two species of *Lithosialis* in the South Wales coalfield links up these measures with those of the Midlands and the North of England, from which twelve families and seventeen genera are known. An intermediate link is supplied by *Lithosialis brongniarti* Mantell from the Coal Measures of Coalbrookdale (Shropshire), while *Lithomantis carbonarius* Woodward, from the Scottish Coal Measures, is a near ally.

The Welsh forms of Palæodictyoptera do not give much assistance in faunal or stratigraphical relation.

The Welsh Blattoids, however, are now sufficiently numerous and varied in character to justify comparison with the more abundant suite of forms recorded from the Coal Measures of Staffordshire and the Pas-de-Calais.

Certain species are common to both areas. *Archimylacris atrebatica* Pruvost, from the Big Vein, Cross Hands, is also found in the Assise d'Anziers, both horizons being Westphalian.

The genus *Phyloblatta* in both areas ranges from the Westphalian upwards into the Radstockian. An *Archimylacris pronotum*, from the Gwernau Level near Maes-y-Cwmmer (South Wales), is more nearly akin to the typical French species *pronotum* of this genus, figured by Prof. Pruvost, than to any British form.

It is, however, when we compare the South Wales examples of Hemimylacridia with the French species that we find the closest relation.

Hemimylacris is represented by two species from seams in the Radstockian of South Wales, comparable with two of Pruvost's species from the Faisceau d'Edouard, Assise de Bruay, which is also Radstockian. *Phylomylacris*, of which ten species are recorded in the Faisceau d'Edouard, is represented by one species from the Loughor vein; by two (possibly three) from the Penyscallen Seam of Beili Glas Colliery, Gorseinon, both in the Radstockian; and by a doubtful species in the No. 2 Rhondda Seam of the Staffordian. With the exception of this last doubtful species, *Phylomylacris* is restricted to the Radstockian in both the Welsh and the Pas-de-Calais areas. The genus *Soomylacris* presents even stronger evidence. Two new species, recorded in the paper, are from the Swansea 5-foot Seam, and the Mynyddislwyn Vein of the Radstockian. Two species are known from the Forest of Dean, extending the range of the genus to the north-east, and one species has been recorded from the Barfreston boring in the Kent Coalfield, which provides evidence of unity with the two species that Prof. Pruvost has recognized from the Insect-Bed of Liévin in the Pas-de-Calais. Thus it may be said that the three typical Hemimylacridian genera found in the South Wales coalfield are present also in the coalfields of Lens and Liévin.

Prof. Pruvost, in his 'Distribution des Faunes Insectes Paléozoiques' p. 318, indicates that the upper beds of the British Staffordian are equivalents of beds of Faisceau d'Ernestine age in the Assise de Bruay.

It seems evident from the distribution of the Welsh insect-wings that this generalization holds good in the Welsh area, for, correlated by the insect-fauna alone, the whole of the Radstockian of South Wales, and a portion of the Upper Staffordian down to the Swansea 2-foot Seam, should be regarded as the equivalent of the Assise de Bruay.

These conclusions also tend to confirm the view of Dr. A. E. Trueman, who, after an exhaustive study of the molluscan zones of the South Wales coalfield and those of the Faisceaux of the Pas-de-Calais Coal Measures, expressed the opinion that the two areas were so similar as to provide a basis for correlation.

Prof. A. H. Cox's suggested correlation of the Coal Measures of South Wales with those of Staffordshire upon lithological grounds seems likely to be supported by the insect-fauna, for, outside the Welsh area, the genera *Archimylacris* and *Aphthoroblattina* are known only from the Shropshire and Staffordshire coalfields.

November 20th, 1929.—Prof. J. W. Gregory, LL.D., D.Sc., F.R.S., President, in the Chair.

The following communication was read:—

'The Geology of the Country between Nant Peris and Nant Ffrancon (Snowdonia).' By David Williams, Ph.D., M.Sc., B.Eng., D.I.C., F.G.S.

The area described lies immediately north of Snowdon, between the Passes of Llanberis and Nant Ffrancon. The general stratigraphical succession is as follows:—

				Thickness in feet.
TERTIARY.		Olivine-Dolerite Dykes.		
LOWER CARADOC to MIDDLE LLANDEILO.	Snowdon Volcanic Suite.	Bedded Pyroclastic Series.	Pumice-tuffs... Upper limit not seen.	
			Andesitic basalt	200
			Banded pumice-tuffs	500
		Lower Rhyolitic Series.	Flinty rhyolite-tuffs	250
			Slates, with tuff-bands	250
			Vitric tuffs, with thin flows	500
			Grits and slates, with tuff-bands	200
			Nodular rhyolites	Up to 50
			Massive and banded rhyolites	200
LOWER LLANDEILO and LLANVIRN.		Gwastadnant Grits, with rhyolites and keratophyre		750
		Talgau lavas (soda-rhyolite and keratophyre)		300
		Dark slates (from about the *Nemagraptus-gracilis* Zone to below the *Didymograptus-murchisoni* Zone)		2000+

		Thickness in feet.
TERTIARY.	Olivine-Dolerite Dykes.	
	—— Arenig Beds unexposed. ——	
CAMBRIAN—		
UPPER.	Ffestiniog Grits	1000
	Maentwrog Slates	1000
	Bronllwyd Grits	Up to 1500
MIDDLE.	Green Slates at the top of the Cambrian 'Slate-Belt'	100
EARLY INTRUSIVES.	Bwlch-y-Cywion 'granite' and Moel Perfedd Granophyre (? Llandeilo age).	
	Dolerite-sills and dykes of pre-cleavage age (? Upper Llandeilo or Caradoc).	

The topmost Cambrian beds, the Ffestiniog or *Lingula* Grits, are of shallow-water origin. Near their base they have yielded *Olenus micrurus*, whereas their topmost 150 feet carry abundant *Lingulella davisii*, and may be equivalent to the *Lingulella* Band of the Portmadoc country. They are faulted against blue-black slates, probably of Lower Llanvirn age. The lowermost graptolites thus far recovered from these slates are referable to the lower part of the zone of *Didymograptus murchisoni*. Upwards, the slates pass into the paler Llandeilo slates with *Glyptograptus teretiusculus*, at the top of which occur the Talgau lavas apparently belonging to the Glyder Fach–Capel Curig volcanic suite. By contrast with the overlying Snowdonian lavas, from which they are separated by the Gwastadnant Grits, these earliest flows are notably sodic.

The Snowdon Volcanic Suite is essentially composed of potash-rhyolites and rhyolite-tuffs, succeeded, near the Devil's Kitchen, by pumice-tuffs and flows of andesitic or basaltic character. The Upper Rhyolitic Series of Snowdon itself is here absent.

Two large acid plutonic masses, Moel Perfedd and Bwlch-y-Cywion, are believed to represent the denuded plugs of the vents from which the Lower Rhyolitic Series was extruded. Differentiation within the Bwlch-y-Cywion 'granite' is discussed, and some results of contact-metamorphism are described.

A number of pre-cleavage sills and dykes of augite-dolerite and spilitic dolerite are intruded among the Llandeilo beds, and some highly decomposed quartz-dolerites are injected into the Llanvirn Slates.

Both the folding and the cleavage, which strike approximately north-east and south-west, are attributed to Caledonian earth-movements, the cleavage following closely upon the folding, but preceding the faulting. 'Cleavage-fans' are conspicuous, two 'synclines' being separated by an 'anticline'. There appears to be no evidence in this area of the post-cleavage thrusting observable on Snowdon.

INTRODUCTION.

Fleming's material is in the Royal Scottish Museum, Edinburgh, and the corals were kindly lent to us by

Dr. J. Ritchie. Most of these were of historical interest only, adding nothing to our knowledge of the species founded by Fleming in his 'History of British Animals'; yet they include the four holotypes, which are here described.

Whilst revising Fleming's types, we have taken the opportunity to describe also certain others, namely, those of the species *Diphyphyllum lateseptatum* and *D. gracile,* which belong to the same genus as Fleming's *Caryophyllea fasciculata*; *Stylastræa inconferta* and *S. basaltiformis,* which bear the same relation to the cerioid *Lithostrotion* as *Diphyphyllum* does to the phaceloid forms of that genus; and *Chætetes radians,* which is conspecific with Fleming's *Favosites septosus.* We also discuss all the genera involved.

We thank Dr. J. Ritchie for the use of the Fleming specimens, and Prof. J. E. Marr for permitting one of us (S. S.) to cut M'Coy's types, which are in the Sedgwick Museum, Cambridge. Such of Lonsdale's specimens as are mentioned are in the British Museum, if not lost.

LITHOSTROTION, Fleming, 1828, p. 508.

Genotype: *L. striatum,* Fleming, 1828, p. 508=*Lithostrotion sive Basaltes minimus striatus et stellatus,* Edward Lhwyd, 1699, p. 124, pl. [xvi.]*; 1760, p. 125, pl. xxiii.

Diagnosis.—Phaceloid and cerioid Rugose Corals, which have, typically, a columella, long major septa, and large tent-shaped tabulæ, usually supplemented at the theca by smaller and nearly horizontal tabulæ. Dissepiments are well developed in the larger species, but absent in the very small forms. Gemmation is non-parricidal. Diphymorphs of *Lithostrotion* have no columella, short septa, flat or distally arched tabulæ, and, in the phaceloid forms, parricidal gemmation.

Lithostrotion=*Stylastræa,* Lonsdale, 1845, p. 619.

Non *Stylastræa,* de Fromentel, 1861, p. 223.

Genotype of *Stylastræa*: *Lithostrotion sive Basaltes minimus striatus et stellatus,* Lhwyd, 1699, p. 124. This is the genotype of *Lithostrotion,* see Smith, 1916, p. 220, therefore *Stylastræa* is an absolute synonym of *Lithostrotion.*

Lonsdale expressly founded *Stylastræa* upon Lhwyd's Coral, but under two misapprehensions: first, that *Lithostrotion etc.,* Lhwyd, had no persistent columella; and, secondly, that *Lithostrotion striatum,* Fleming, was generically identical with Fleming's *L. floriforme* (Martin's "*Erismatolithus Madreporites* (*floriformis*)"). Even if Lhwyd's coral has some ambiguous features, it certainly has a columella, and Fleming explicitly founded his *Lithostrotion striatum* upon it. What we do not completely know are certain structural details and the exact size of the corallites. *Madrepora vorticalis*, Parkinson (1808, p. 45, pl. v. figs. 3 & 6) and *Astrea basaltiformis*, Conybeare & Phillips (1822, p. 359), were also founded upon Lhwyd's description and figure. Martin's coral is quite different and is well known.

---

* See S. Smith, 1916, p. 220. The matter of the genotype of *Lithostrotion* is at present before the International Committee of Zoological Nomenclature, and we intend to discuss it further in a later paper.

It is interesting to note that non-columellate (diphymorph) corallites are much rarer among cerioid colonies of *Lithostrotion* than they are among the phaceloid forms. Both Lonsdale and M'Coy, however, have described examples of cerioid non-columellate *Lithostrotion* as *Stylastræa conferta* and *S. basaltiforme*, respectively. These differ from the phaceloid non-columellate *Diphyphyllum* in their marginal, non-parricidal gemmation; in their tabulæ, which are not differentiated into a distinct inner and outer series; and in their coarser dissepiments. We have seen that *Stylastræa* is an absolute synonym of *Lithostrotion*; and, therefore, propose the name {*Diphystrotion*} for these diphymorphs of cerioid *Lithostrotion*. It will be noted that {*Diphyphyllum*} and {*Diphystrotion*}, though differing from *Lithostrotion* in what might reasonably be supposed to be generic characters, yet do not constitute true genera, but are expressions of a trend which some external or internal stimulus has provoked to rapid development in a colony, or in certain individuals of a colony, so that the individual anticipates an evolution which is familiar in other stocks, both nearly and distantly related, and is there seen to be a phyletic, and not an individual, trend—a trend which results in new generic forms. We propose to call these forms which anticipate, but do not constitute, new genera—*genomorphs*; and to indicate them by genomorphic names, which are to be recognized as such by being placed in braces.

Moreover, in order to avoid confusion, the diphymorph trivial name might also be retained after the genomorphic name. Thus, "*Lithostrotion* sp. {*Diphyphyllum lateseptatum*} probably = *Lithostrotion* {*Diphyphyllum*} *martini*" would mean that what was formerly considered to be the species *Diphyphyllum lateseptatum* is but a diphymorph form of *Lithostrotion*, probably of *L. martini*. By this means a new concept has been expressed by adding genomorphic names to Linnæan nomenclature.

Lithostrotion, Fleming, 1828, p. 508, genomorph {*Diphyphyllum*, Lonsdale}.

Genomorphotype: *Diphyphyllum concinnum*, Lonsdale, 1845, p. 624, pl. A. fig. 4 (the genotype of the original genus *Diphyphyllum*). The type of *D. concinnum* is lost; we therefore base *Diphyphyllum* on *D. lateseptatum*, which, if not conspecific, is certainly congeneric with *D. concinnum*.

Diagnosis.—Phaceloid *Lithostrotion*, which have no columella, or one which is reduced to spines on successive tabulæ. The axial tabulæ may be flat or convex, but have downturned edges, which either meet the tabulæ below them or extend to the dissepimental wall; the outer smaller tabulæ abut against the inner tabulæ. The dissepiments, which are small, are well developed in the larger forms. Gemmation is parricidal.

Remarks.—*Diphyphyllum* is generally used not only for phaceloid forms of *Lithostrotion*, but for any phaceloid coral with short septa. Such corals in some instances have followed the same trend as the "diphymorphs" of *Lithostrotion*—a trend almost universal in Rugose lineages, in which the septa retreat from the axis; in other instances their short septa may constitute a primitive character. We would restrict the genomorphic name {*Diphyphyllum*} to the diphymorphs of *Lithostrotion*, considering, as we have already suggested, that in this group the diphymorph structure is a condition due to other causes than normal phyletic development; and that a suitable stimulus may start any individual along this trend. Diphymorph variants accompany columellate *Lithostrotion* throughout the known range of the genus; but they first appear at a horizon slightly lower than that at which the lowest columellate *Lithostrotion* has yet been found. In these early diphymorphs the axial tabulæ are almost horizontal and inosculate with the small outer tabulæ (*Diphyphyllum* α of S. Smith *). It is probable, therefore, that they represent a primitive stage of *Lithostrotion*, while the characteristically later diphymorphs (*Diphyphyllum* β of S. Smith *) with strongly arched inner tabulæ show a reversionary trend. This point, however, needs to be established by further investigation.

Lithostrotion sp. {*Diphyphyllum concinnum* (Lonsdale)}.

Diphyphyllum concinnum, Lonsdale, 1845, p. 624.

Carboniferous Limestone. Hill of Tchirief, Kamensk, on the River Issetz, eastern side of the Ural Chain.

---

* 1928, p. 114.

The syntypes of {*Diphyphyllum concinnum*} cannot be traced, but they consisted, according to Lonsdale (*loc. cit.*), of "one subdivided stem (figs. 4 *a*, 4 *b*) and several portions of others (fig. 4); the larger having a nearly uniform diameter of four and a half lines [9 mm.], and the smaller of three and a half lines." Lonsdale's description and figures clearly indicate a form which closely approaches M'Coy's {*Diphyphyllum lateseptatum*}, both in details of structure (*q. v.*) and in size, but slightly larger, and with the dissepimental area relatively wider. From Lonsdale's statement it would appear that the axial tabulæ in {*D. concinnum*} occupied only half the diameter of the corallite, whereas in {*D. lateseptatum*} they occupy two-thirds. There are over 30 major septa. Since the type-specimens are no longer available, Lonsdale's description may be quoted here in full: "Stems cylindrical, nearly smooth; crossed externally by close, fine, waved lines, and stronger, unequal, distant bands; lamellæ numerous, variable; inner surface of plates furrowed strongly upwards and outwards; central area, diaphragms flat, convex or irregular; intermediate area, principal lamellæ exceeding 30, more or less waved, intermediate very unequal; interstitial prolongations of diaphragms inclined sharply downwards, accessory plates nearly horizontal; outer area, lamellæ variable in strength and range, interstitial plates largely vesicular; terminal cup deep, lined by edges of the lamellæ, no central boss."

The statement in the original description that the inner surface of the plates (septa) are furrowed rather suggests that the undulations which characterise the sides of the septa of the holotype of *Stylastræa inconferta* are also present in this coral. Until topotype material is available, this form cannot be certainly identified nor the name authoritatively used.

Lithostrotion sp. {*Diphyphyllum lateseptatum* (M'Coy)}. (Pl. VII. figs. 1–4.)

Diphyphyllum lateseptatum, M'Coy, 1849, p. 8; 1851, p. 88, pl. iii. *c.* figs. 10, 10 *a*, *b*.

Holotype.—Sedgwick Museum, Cambridge. Specimen No. 123, Carboniferous Limestone, Corwen.

The specimen is a piece of dark-coloured limestone, 4·5 cm. × 3·5 cm. × 0·3 cm. It has been broken, but the pieces fit together. It enclosed fourteen fairly straight, more or less complete, corallites, which stand out from its upper weathered surface, and are well exposed as longitudinal sections on one of its sides. The type-material also includes an isolated and broken corallite, figured by M'Coy (fig. 10 *a*), and without doubt detached from the same specimen. M'Coy's remark that the corallites were upwards of 8 inches in length presupposes either that the holotype was originally longer or that he had other specimens as well.

The largest corallite is 8 mm. in diameter, with thirty-four major septa 2 mm. to 2·5 mm. long; and the smallest corallite is only 4 mm. in diameter. The minor septa are one-third the length of the major, *i. e.*, less than 1 mm.

In transverse sections of this and in most other sections of {*Diphyphyllum*} the major septa appear to end against a complete ring, which suggests an aulos, or an inner wall, but this is merely formed by the intersections of axial tabulæ. The character of the tabulæ is well seen in the longitudinal sections of the topotypes (Pl. VII. figs. 3 *b*, 4 *b*). They include two series of plates, of which the inner series are horizontally disposed, convex, and superposed one upon another, forming an axial column: they are unequally spaced, some being very close together, others 1·5 mm. apart. The outer tabulæ, which slope downwards and towards the periphery, occupy a very narrow area, and abut, on the one hand, against the down-bent margins of the inner tabulæ and, on the other, against the innermost dissepiments. Here and there, however, the wall of the axial column is broken by an inner tabula extending to the theca, instead of curving round to touch the tabula below. The dissepiments are small and strongly arched, but vary in size. There are usually two rows, seldom only one, sometimes three. In a corallite 6 mm. in diameter the axial tabulæ occupy 4 mm., and the outer tabulæ and dissepiments together 1 mm. on each side.

It is to be noted that an impersistent columella is often represented by spines on successive tabulæ, and that some specimens (*e. g.*, British Museum R. 4506) have the rudiments of an axial complex like that described in *Nemistium edmondsi* (Smith, 1928, pp. 116-7, pl. v. figs. 1-4), into which form "species" of {*Diphyphyllum*} imperceptibly merge.

Lithostrotion sp. {*Diphyphyllum gracile* (M'Coy)}.
(Pl. VII. figs. 5 & 6.)

Diphyphyllum gracile, M'Coy, 1851[2], p. 168; 1851, p. 88, text-figs. *d*, *e*, and *f* on p. 88.

Holotype.—Sedgwick Museum, Cambridge. Specimen 122 (Carboniferous). The Impure Limestone of Lowick, Northumberland.

This consists of part of a corallum, embedded in a piece of dark-coloured limestone 10 cm. × 7 cm. × 5 cm., from which a small piece has now been cut in order to provide the thin sections here figured.

The slender cylindrical corallites are erect and closely packed. Their diameter is usually rather more than 3 mm., but one or two—much bigger than the rest—are as much as 6 mm. There are about 20 major septa between 0·5 mm. and 1 mm. long. The minor septa are very short indeed, usually being less than one-fourth the length of the major, and thus hardly noticeable in many of the corallites. The axial tabulæ, which may be as much as 1 mm. apart and are fairly evenly spaced, are arranged as in the other forms of {*Diphyphyllum*}. They thus appear strongly arched, although their crest may be flat. They occupy an area 2 mm. in diameter, *i. e.*, two-thirds of the corallite; whilst the narrow peripheral area about 0·5 mm. wide is occupied mainly by the outer tabulæ, which are nearly horizontal but slope slightly downwards towards the periphery. Some dissepiments may be present, but these at most form merely a single row and are not persistent. A columella is sometimes represented by a series of short spines, which rise from successive tabulæ, but do not reach the tabula above.

On the whole, M'Coy's description is very accurate, but he evidently confused the outer tabulæ with the dissepiments. We have frequently noted corals intermediate in character between M'Coy's type of {*D. gracile*} and small columellate *Lithostrotion*—*L. junceum* (Fleming) as well as small forms of *L. irregulare* (Phillips).

Lithostrotion sp. {*Diphyphyllum fasciculatum* (Fleming)}. (Pl. VII. figs. 7 & 8.)

Caryophyllea fasciculata, Fleming, 1828, p. 509.

Non *Caryophyllia fasciculata*, Lamarck, 1816, p. 226 (Recent).

Non *Lithodendron fasciculatum*, Phillips, 1836, p. 202, pl. ii. figs. 16 & 17.

Non *Caryophyllia fasciculata*, de Koninck, 1842, p. 17, pl. D. figs. 5 *a–c*, pl. G. figs. 9 *a, b*.

Non *Lithodendron fasciculatum*, Keyserling, 1846, p. 170, pl. iii. figs. 2, 2 *a–b*.

Non *Diphyphyllum fasciculatum*, D'Orbigny, 1850, p. 159.

? *Lithodendron fasciculatum*, Portlock, 1843, p. 335.

Original description.—" Crowded, branched, round, nearly cylindrical, slightly flexuous, and about a quarter of an inch in diameter.—Madreporite, *Park.* Org. Rem. 51, t. vi. f. 8. —Madrepora cespitosa, *Mart.* Derb. t. 17, *Carboniferous Limestone.*"

Syntypes.—There are two specimens in the Fleming collection labelled "*Caryophyllea fasciculata*," namely 1870.14.374 and 1870.14.337. The first of these (1870.14.374) is here chosen as the lectotype. This is from Skate Craig, Dunbar.

Lectotype.—The specimen measures 18 cm. × 10 cm. × 5 cm.; the coral and matrix are light-coloured. The corallites, which have an average diameter about 5 mm., are crowded and rather flexuous. The structure is the same as that of the other three forms of *Diphyphyllum* here described. There are about twenty-four major septa about 1·5 mm. long; the minor septa attain only half, or less than half, this length. The axial tabulæ are approximately 3 mm. in diameter, and are generally nearly 1 mm. apart, but the intervals between them vary, sometimes being somewhat more than 1 mm. and sometimes much less. The outer tabulæ and the dissepiments together occupy 1 mm. on each side of the axial tabulæ. The dissepiments usually fill a narrower area than the outer tabulæ, and are typically arranged in one row only, but here and there there are two rows. The dissepimental vesicles contain much stereome.

It is possible that Fleming knew of Lamarck's *Caryophyllia fasciculata* when he named this coral, but we cannot assume this, for he makes no reference to Lamarck; and since his species belongs to an entirely different genus and class, Fleming's name may be used for those forms of {*Diphyphyllum*} that are intermediate in size between {*D. lateseptatum*} and {*D. gracile*}, and otherwise agree with his type of *Caryophyllum fasciculata.* The species should, therefore, be designated as *Lithostrotion* sp. {*Diphyphyllum fasciculatum* (Fleming)}.

Lithostrotion, Fleming, 1828, p. 508, genomorph {*Diphystrotion*, nov.}.

Genomorphotype: *Stylastræa inconferta*, Lonsdale, 1845, p. 621 pl. A. figs. 2, 2 *a–c*.

Diagnosis.—Cerioid *Lithostrotion* in which there is no columella, or one which is reduced to spines on successive tabulæ, and in which the tabulæ are slightly convex or flat and in most cases complete. The dissepimental tissue is typically coarse. Parricidal gemmation has not been observed.

Remarks.—{*Diphystrotion*} leads on to *Thysanophyllum*, Thomson (strictly interpreted by the genotype), which has a thoroughly lonsdaleoid border; but not to "*Thysanophyllum*" *vermiculare*, which is the corresponding development of the fasciculate {*Diphyphyllum*}.

Lithostrotion sp. {*Diphystrotion inconfertum* (Lonsdale)}. (Pl. VII. figs. 9–13.)

Stylastræa inconferta, Lonsdale, 1845, p. 621, pl. A. figs. 2, 2 *a–c*.

Holotype.—British Museum, specimen R. 17562, Kossatchi-Datchi, South of Miask, eastern side of Ural Chain (about 900 miles due E. of Moscow). There are isolated corallites and sections of parts of the same specimen separately numbered.

The specimen, which is 10 cm. long and 5·5 cm. × 4 cm. transversely, consists of a few easily separable prismatic corallites, the largest of which is about 10 mm. in diameter. Most of them are to some extent crushed and broken. The material is re-crystallized (and to some extent dolomitized); and the vesicular tissue is not completely filled by mineral calcite, although it contains much stereome. The epitheca is finely striated longitudinally and wrinkled transversely. This, and the general shape, is very well shown in Lonsdale's figure (pl. A. fig. 2).

In most of the corallites there are eighteen major septa, generally including one septum much longer than the rest, like that of *Thysanophyllum orientale*, Thomson. This counter-septum reaches beyond the axis, whilst the others only extend inwards 2 to 4 mm. The minor septa are very feebly developed, few being as much as 1 mm. In most cases the septa reach the epitheca, but here and there—on one side or another of a particular corallite—they end peripherally against a large dissepiment. The septa are thin and, seen in transverse section, rather crooked, particularly the long counter-septum. The sides of the septa, where exposed by longitudinal fracture *, are corrugated by sinuous folds, which slope downwards axially and are themselves transversed at right angles by very fine and rather faint corrugations.

There is no continuous columella, but some axial structures recalling those in *Nemistium edmondsi* † may occur on successive tabulæ.

The tabulæ, which may or may not be complete, are convex distally, reach the theca, and are not differentiated into distinct series, as in the forms of {*Diphyphyllum*} which we have described. They are unequally distributed, and may be as much as 2 mm. apart, although the average distance between them is less than 1 mm.

---

* This particular specimen breaks longitudinally in an unusual manner; namely, along the sides of the septa (which are thus exposed to view), owing to some incoherence between the septa and the matrix which fills the vesicular tissue between them.

† Smith, 1928, pp. 112–120.

The dissepiments are large, and form only a single, or at most a double, row of strongly-arched plates. The width of the dissepimental area is about the radius of the corallite.

Lithostrotion sp. {*Diphystrotion kendalense,* new form}. (Pl. VII. figs. 14 & 15.)

"*Stylastræa basaltiformis* (Phill. sp.)," M'Coy, 1851, p. 107, no figure.

Holotype.—Sedgwick Museum, Cambridge. Specimen 130. Specimens 131 and 133 parts of the same piece of coral. Carboniferous Limestone, Kendal.

The holotype is a little over 25 cm. in length, and consists of unusually long, remarkably straight, easily separable corallites, some of which run the entire length of the specimen, and most of them nearly as far. The material is well preserved, but appears to be a little dolomitized, and here and there the interstices of the coral are free from mineral matter. As in *S. inconferta*, the corallites are lightly striated and transversely wrinkled, and attain a maximum diameter of about 10 cm., but have about twenty-five major septa, which are not more than 3 to 4 mm. long. The septa reach the epitheca, but the major septa are very often interrupted by the large dissepiments, and appear discontinuous in transverse section. For the most part the axial region is quite free of longitudinal tissue. The tabulæ, which are nearly all complete, are flat or sagging, but bend downwards near their periphery. The dissepiments vary considerably in size, some being distinctly large and others quite small. The dissepimental area occupies about half the radius of the corallite.

{*D. kendalense*} closely resembles {*D. inconfertum*}, but shows some small differences, as may be seen from the description and in the figures. The flatter tabulæ, almost entire absence of any axial structure, and greater development of dissepimental tissue are the chief. The septa, moreover, do not show the corrugations mentioned in Lonsdale's form.

"*Stylastræa basaltiformis* (Phill. sp.)," M'Coy, as we have seen, is a diphymorph, and is not *Astrea basaltiformis*, Conybeare & W. Phillips, which was founded on Lhwyd's figure already quoted (p. 178). It is therefore necessary to re-name M'Coy's form, and, since we consider {*Diphystrotion*} to be a genomorph of *Lithostrotion*, we name it *Lithostrotion* sp. {*Diphystrotion kendalense*}.

It is not possible to tell from John Phillip's figure or his description of "*Cyathophyllum basaltiforme*" whether the form is, or is not, identical with M'Coy's.

AULOPHYLLUM, Edwards & Haime, 1850, p. lxx.

Genotype: *Clisiophyllum prolapsum*, M'Coy, 1849, p. 3; 1851, p. 95, pl. 3 *c.* figs. 5, 5 *a.* Carboniferous Limestone, Derbyshire. = *Turbinolia fungites*, Fleming, 1828, p. 510. = *Fungites*, Ure, 1793, p. 327, pl. xx. fig. 6.

Diagnosis.—Simple, trochoid Rugose corals, often of large size, with a compact well-defined central column, which, seen in transverse section, has a cuspidate outline and is built up of closely-packed vertical and horizontal elements. The major septa do not usually extend quite to the axial complex. The tabulæ are small and arched, and slope down towards the periphery. There is a well-developed peripheral zone of numerous small dissepiments.

Remarks.—*Aulophyllum* differs from all other Clisiophyllids in having the number of radial lamellæ within the central column greater than the number of septa, and from most in having no axial plates. In other respects it agrees with the typical Clisiophyllids.

Aulophyllum fungites (Fleming).

Turbinolia Fungites, J. Fleming, 1828, p. 510.
Aulophyllum fungites (Fleming), Edwards & Haime, 1851, p. 413; 1852, p. 188.

Fleming describes the species, which is the genotype of *Aulophyllum*, as: "Inversely conical, lengthened; more or less bent; longitudinally striated, with irregular transverse wrinkles; star concave, with a large central axis. Fungites, *Ure*, Ruth. 327, lxx. fig. 6.—In *Carboniferous Limestone*, common; frequently termed *Rams' horns*." Eight syntypes (Specimens 1870.14.428) remain in Fleming's collection, most of them being typical material and conspecific with D. Ure's specimen of *Fungites* (1793, p. 327, p. xx, fig. 6), to which Fleming refers, and which has been virtually chosen as the lectotype; although in the detailed description and summary of the literature of *Aulophyllum fungites* by S. Smith (1913, pp. 51–77, pls. v.–ix.), and in Gregory's later remarks (1917, pp. 223–4), this was not definitely stated. In order to avoid any future ambiguity, we hereby choose Ure's figured specimen of *Fungites* as the lectotype of *Turbinolia fungites*, Fleming.

It may be added that Thomson (1882, p. 481) referred Ure's specimen of *Fungites* (of which he cut sections) to *Cyclophyllum*, Duncan & Thomson, 1867, and figured it as *C. fungites*. But it has been shown conclusively that *Cyclophyllum*, Duncan & Thomson, is identical with *Aulophyllum* (see S. Smith, 1913, pp. 54–55, and Gregory, 1917, pp. 223–4). It may also be pointed out that in 1867 Duncan and Thomson founded *Cyclophyllum* on two syntypes, namely, *Aulophyllum fungites* (*Turbinolia fungites*, Fleming) and *A. bowerbanki*, Edwards & Haime, of which the former was regarded by Edwards and Haime as conspecific with the genotype of *Aulophyllum*; and we consider that the two forms are identical.

Gregory (1917, p. 273) chose *A. bowerbanki*, Edwards & Haime, as genolectotype of *Aulophyllum*, but Edwards and Haime (1850, p. lxx) had already given *Clisiophyllum prolapsum* as the genoholotype.

CHÆTETES, G. Fischer von Waldheim, 1830, sig. *d*, 4; 1837 (second edition), p. 160.

Genosyntypes: *Chætetes radians*, G. Fischer v. Waldheim, 1830, sig. *d*, 4.
Chætetes dilatata, " " " "
Chætetes cylindrica, " " " "
Chætetes incrustans, " " " sig. *e*, 1.
Chætetes gigantea, " " " "
Chætetes jubata, " " " "

Genolectotype: *Chætetes radians*, G. Fischer von Waldheim, 1830, sig. *d*, 4: 1837, p. 160, pl. xxxvi. fig. 3 (referred to in text as fig. 6), Carboniferous. Miatchkova (14 miles S.W. of Moscou), Russia. See H. M. Edwards and J. Haime, 1850, p. lxi.

Diagnosis.—Cerioid or meandroid Tabulate corals, which form tumular or stratiform masses, and have small corallites with thin, complete, horizontal tabulæ, but no septa, and probably no mural pores. The walls separating the individual corallites are often incompletely formed, and may appear [illegible] y [illegible], and [illegible]

Remarks.—[illegible] Waldheim's descriptions of the genosyntypes of *Chætetes* are in themselves too inaccurate for diagnostic purposes, nevertheless the figures clearly and unmistakably show that the corals belong to the same genus, and probably all to the same species, as the coral described and figured by Lonsdale, 1845, p. 595, pl. A. figs. 9, [illegible] *radians*, from Borovitchi etc., Government [illegible] Lonsdale's figured specimen is in the British [illegible] *Chætetes radians* is interpreted by [illegible] conspecific with *Favosites septosus*, Fleming. [illegible] Lonsdale's specimen the tabulæ are grouped [illegible] wide apart and near together, [illegible] are fairly equally distributed, [illegible] observed both conditions in British and Russian specimens, and consider the distribution of tabulæ to be due to environmental conditions, and not to be a congenital character. The walls are thicker in Lonsdale's specimen than in Fleming's, and in consequence of this the corallites of Lonsdale's specimen have a much more rounded interior.

Fischer von Waldheim's statement that the tubes were without diaphragms can be explained, either by the fact that the tabulæ had been destroyed by silification, which, he says, affected many of his specimens, or that he did not notice the thin and distant tabulæ on its broken surface.

Both Edwards and Haime (1851, pp. 259–263; 1852, pp. 157–8) and Thomson (1882, p. 201) regarded *Chætetes radians*, Fischer von Waldheim, and *Favosites septosus*, Fleming, as distinct species, and even as distinct genera, on the grounds that the latter had, and the former had not, mural pores. Nicholson and Etheridge (1877, pp. 366–367), on the other hand, could detect pores in neither species, and considered the two forms to be at least congeneric. As to the mural pores, we have not been able to detect them ourselves, but Thomson claims to have done so in specimens from Scotland (1882, p. 197). If present, they are necessarily very small, and would easily be obliterated in the process of mineralization; whereas those of the genotype of *Alveolites* are large.

Two clear trends are manifest in *Chætetes*, namely, a thickening of the wall and the development of such meandroid colonies as are exhibited in an exaggerated degree by the form from Ireland recently described and figured by Smyth (1925, pp. 319–320, pls. xiv., xv.).

Chætetes radians, Fischer von Waldheim, *interp.* Lonsdale.

Chætetes radians, Fischer von Waldheim; Lonsdale, 1845, p. 595, pl. A. figs. 9, 9 *a*. This is probably *Chætetes radians*, Fischer von Waldheim, 1837, p. 160, pl. xxxvi. fig. 3 (*non* fig. 6 as in text): it is certainly *Favosites septosus*, Fleming

Lonsdale's material.—Specimens from Kaluga (Government of Kaluga, 100 miles S.S.E. of Moscow); Borovitchi (Government of Novgorod, 240 miles N.E. of Moscow) and Vitegra, on S.W. side of Lake Onega (Government of Olonetz, nearly 400 miles N. by E. of Moscow).

Neotype.—On the assumption that Fischer von Waldheim's material is lost, we select Lonsdale's figured specimen, British Museum 26356, Carboniferous, Kaluga or Vitegra (old label reads Kaluga and Vitegra), as neotype.

The specimen, 10 cm. high, 6·5 cm. wide, is part of a large tumular colony of radiating, separable, prismatic corallites.

The corallites are fairly regular in section, and are almost 0·5 mm. in diameter. They have thick walls, rounded angles, and very thin tabulæ, which may be as much as 5 or 6 mm. distant or may be very close together. The tabulæ occur at the same level in neighbouring corallites, and form continuous platforms. Wide bands of widely-separated tabular platforms alternate regularly with narrow bands of closely-packed platforms, as shown by Lonsdale's fig. 9. It should be added, however, that the widely-separated tabulæ of one part of the corallum may approximate in another part of the mass if the individual bands are followed far enough. The neotype also exhibits very clearly the incomplete walls mentioned in our diagnosis and well illustrated by Lonsdale in fig. 9 *a*.

Chætetes septosus (Fleming).
(Pl. VIII. fig. 1.)

Favosites septosus, Fleming, 1828, p. 529.
Alveolites septosa, Edwards & Haime, 1851, p. 259; 1852, p. 157, et auctt.

Holotype.—Specimen 1870.14.123, Fleming Collection, Royal Scottish Museum, Edinburgh. Carboniferous Limestone. No locality.

The black holotype exactly answers Fleming's description: "Hemispherical, nearly 2 inches in diameter, the tubes radiating from the centre irregularly, divided internally by simple transverse plates.—*Carboniferous Limestone*." It is a small colony, 7 cm. in diameter and 4 cm. high. The base is a broken surface. The corallum has been cut longitudinally, and the face of each half roughly polished.

The corallites radiate from a centre, and the colony has the appearance, characteristic of *Chætetes*, of having been built up of several concentric layers. The corallites are prismatic and fairly uniform in size, averaging 0·75 mm. in diameter. The tabulæ are complete, horizontal, and fairly equally distributed at intervals of about 0·5 mm. An incomplete wall is present in many of the corallites, and a slight tendency to assume the meandrine condition is seen locally.

Edwards and Haime's description (1852, p. 157), based on material from various localities, thus agrees very closely with the type.

J. Thomson's remarks upon "*Alveolites septosa*" (1882, p. 205; 1883, p. 344) more fully describe the form, and are perhaps even more accurate in detail, but we disagree with his statements that the corallites are from 5 to 11 lines long, since they may attain a length of several centimetres if not interrupted by the superposition of new growth upon old, which is frequent and referred to by Edwards and Haime (1852, p. 157).

Chætetes depressus (Fleming). (Pl. VIII. fig. 2.)

Favosites depressus, Fleming, 1828, p. 529.
Alveolites depressa, Edwards & Haime, 1851, p. 260; 1852, p. 158, et auctt.

Holotype.—Specimen 1870.14.122, Fleming Collection, Royal Scottish Museum, Edinburgh. Carboniferous Limestone. No locality.

The original description reads:—"An extended plate about an inch in height, tubes vertical, rather smaller than the preceding, and less divided.—*Carboniferous Limestone*," and this agrees so closely with specimen 1870.14.122 that there can be little doubt that it is that which Fleming had in mind when he wrote these words. It is a flat piece of black limestone, 8 cm. × 2·5 cm., enclosing a thin band of coral 2·5 cm. in thickness. The small parallel corallites are very well exposed on the weathered surface, where the coral stands out white (although crossed by numerous thin black lines) from the dark matrix, and the separable character of the "tubes" is clearly demonstrated.

The corallites are sub-prismatic, nearly cylindrical, and average less than 0·2 mm. in diameter. As far as one is able to judge, the tabulæ are unevenly distributed, in some places lying close together, but in others far apart.

Chætetes depressus is easily distinguished from *Ch. septosus* by its very much smaller corallites, which are only about one-fourth the diameter of the large form. Whilst both species may form extensive stratiform growths, that habit is usual in *C. depressus*, whereas a tumiform shape is more general in *C. septosus*.

ALVEOLITES, Lamarck, 1801, p. 375.

Genosyntypes: *Alveolites escharoides*, Lamarck, 1801, p. 376 (l'astroïte de Guettard, 1770, p. 499; pl. xlv. fig. 1).
Alveolites suborbicularis, Lamarck, 1801, p. 376 [Devonian, neighbourhood of Dusseldorf].

Genolectotype: *Alveolites spongites*, Steininger, 1831; 1834, p. 334, pl. xx. figs. 4, 4 *a–c*. = *Calamopora spongites*, var. *tuberosa*, Goldfuss, 1826, p. 80, pl. xxviii. figs. 1 *a*–1 *e*. See Edwards & Haime, 1850, pl. lxi. = *Alveolites suborbicularis*, Lamarck.

Diagnosis.—Massive tabulate corals, which form large colonies built up of superposed layers enwrapping some nucleus. The corallites are small, very oblique, more or less triangular in section, and have moderately thick walls, perforated by a few large mural pores. The septa may be altogether suppressed, but are typically represented by a single septum on the lower lip of the very oblique calice.

Remarks.—The characters distinguishing *Alveolites* from *Chætetes* have been thoroughly discussed by Nicholson and Etheridge, 1877, and again by Nicholson, 1879, pp. 117–125 and 260–266. The form of the calice and the solitary septa are well illustrated by Goldfuss's figure (1826, pl. xxviii. fig. 1 *c*). The young corallites arise at the angles between the older ones.

Fig. 2. *Chætetes depressus* (Fleming) = *Favosites depressus*, Fleming. Holotype. Royal Scottish Museum, Fleming Collection, No. 1870.14.122. Lower Carboniferous (Scotland ?). × 3·5.

XIV.—*Thysanoptera from Africa.*

By DUDLEY MOULTON, San Francisco, California.

THIS paper includes a record of various species of the Terebrantia which have been received principally from Mr. Frederick Laing of the British Museum, London, who has forwarded collections made by Mr. R. E. Turner. Collections from Messrs. A. Cuthbertson and Rupert W. Jack, Rhodesia, and Mr. A. W. J. Pomeroy, Gold Coast, are also included. Another paper will be offered shortly on those species belonging to the Tubulifera. I wish to express my sincere appreciation to these men, who, by their cooperation, have made this paper possible.

Superfamily **ÆOLOTHRIPOIDEA**, Hood.

Family **Orothripidæ**, Bagn., 1926.

AUDIOTHRIPS, gen. nov.

Antennæ 9-segmented, ovipositor upturned and closely related to *Erythrothrips*, Moulton, except that in this new genus the maxillary palpus has five segments instead of eight, and the sense-areas on the third and fourth antennal segments are elongate, extending the full length of the segments, while in *Erythrothrips* they are much shorter and occupy a position only in the distal ends of the segments. This genus approaches *Franklinothrips*, Back, in the great length of the sense-areas and by the elongate third antennal segment, which, however, is much shorter and broader in *Audiothrips* than in *Franklinothrips*.

Genotype, *Audiothrips perplexus*, sp. n.

1. *Audiothrips perplexus*, sp. n.

Female holotype.—Colour of body and legs uniformly deep brown. Antennal segments 1, basal three-fourths of 2 and 4 to 9 concolorous with head; tip of 2 and all of 3 whitish, 4 whitish at base gradually shading to brown at tip. Wings whitish with a dark longitudinal band extending from extreme base, including scale, to tip. This brown band is somewhat narrower in basal third and wider in middle third.

Total body-length 2·5 mm.; head, length ·23 mm., width ·23 mm.; prothorax, length ·16 mm., width ·23 mm.; pterothorax, width ·35 mm.; greatest width of abdomen ·43 mm. Antennæ: length (width) i. 45 (42), ii. 51 (33), iii. 174 (27), iv. 120 (27), v. 60 (24), vi. 45 (24), vii. 48 (21); viii. 24; ix. 12; total length 600 μ.

Head subquadrate; cheeks slightly arched, without conspicuous spines. Eyes extending posteriorly on ventral side. Ocelli normal. Maxillary palpi geniculate, with five segments, although the sutures between the second and third and third and fourth are more or less indistinct. Labial palpi 4-segmented, basal joint very small. Antenna with nine segments, 2·6 times as long as head, segment 3 elongate-cylindrical, ·8 as long as head and 6·5 times as long as wide.

Segment 4 also elongate-cylindrical and ·75 as long as segment 3; 5, 6, and 7 almost subequal, 8 and 9 small, conical, and closely joined to 7. Sense-area on segment 3 narrow, slightly enlarged, and bent at distal end, extending along outer side to near extreme base; sense-area on segment 4 similarly shaped, and also extending to extreme base of segment.

Prothorax small, about as wide as head and ·7 as long, without conspicuous markings or spines. Pterothorax with sides evenly arched. Legs long and slender. Fore femora only very slightly larger than middle and hind femora. Each fore tarsus with a hook-shaped tooth. Wings fully developed, with ring-vein, two longitudinal veins, and four cross-veins.

Abdomen elongate-ovate, with prominent spines only on ninth and tenth segments.

This species resembles *Erythrothrips arizonæ*, Moulton, in shape of body and colour of wings. The third antennal segment resembles *Æolothrips nasturtii*, Jones, but is somewhat longer. It is difficult to state with certainty whether the sutures between the second and third and the third and fourth segments of maxillary palpi are complete in the holotype; they are distinct in the paratype. The sense-areas of third and fourth antennal segments extend over the entire length of the segments as in *Franklinothrips*.

Type material.—Female holotype (Moulton no. 2838) and one ♀ paratype (no. 2831), taken from an unknown host, iii. 1927 (*R. E. Turner*). Holotype deposited with British Museum, paratype in author's collection.

Type-locality.—Orange Free State, South Africa.

Family Æolothripidæ, Uzel, 1895.

2. *Æolothrips brevicornis*, Bagnall.

One ♀ specimen taken at Mossel Bay, Cape Province, viii. 1924 (Moulton no. 2845); one ♀ at Goerge, Cape Province, vii. 1920 (no. 2855); one ♀ taken at Drakensberg, Natal, in 1926, elevation 6500 feet (*R. E. Turner*) (no. 2874). Specimens nos. 2855 and 2874 deposited with the British Museum, no. 2845 in author's collection.

3. *Æolothrips scabiosatibia*, sp. n.

Female holotype.—Colour uniformly dark brown, except segment 3 of antenna, extreme tip of 2, tarsi, and the median portion of fore tibiæ, which are yellowish. Fore wings with two dark cross-bands, hind wings without noticeable colouring.

Total body-length 1·66 mm. (somewhat distended); head, length ·16 mm. (head-length of paratype ·15 mm., width ·18 mm.); prothorax, length ·15 mm., width ·25 mm. Antennæ: length (width) i. 24 (30), ii. 48 (27), iii. 75 (24), iv. 60 (27), v. 60 (27), vi–ix. combined 39 μ; total length 316 μ.

This species is closely related to *Æolothrips brunicornis*, Bagnall, in that each fore wing has two dark cross-bands, typical of the *A. fasciatus*-group, antennal segments 6–9 are subequal and together, like *A. brevicornis*, are much shorter than 5, segments 4 and 5 are subequal, and about four-fifths as long as segment 3. Entire antenna is moderately stout and approximately twice as long as head; sense-areas on segments 3 and 4 moderately broad, extending two-thirds the length of the segments. This species is especially characterized by the unusually roughened fore tibiæ, which are normally spiny on the dorsal side, but on the ventral side each spine arises from the side of a small wart or tubercle, which makes the surface of the tibiæ extremely rough. The spines of the middle and hind tibiæ are normal; unfortunately the fore tibiæ are broken from the second paratype, but after measurement and comparison I have referred the second paratype to this species rather than to *brevicornis*.

Type-material.—Female holotype (Moulton no. 2905); two ♀ paratypes (nos. 2902 and 2904), collected from an unknown host-plant in iv. 1925 (*R. E. Turner*). Holotype and one paratype deposited with British Museum, one paratype in author's collection.

Type-locality.—Ceres, Cape Province, South Africa.

4. *Rhiphidothrips turneri*, sp. n.

Male holotype.—Colour uniformly dark brown except tips of second and third antennal segments, which are lighter (unfortunately the antenna is broken off beyond the second segment, but the third and fourth segments of one antenna are present, though detached; the fore and middle pair of legs are also lost). Hind legs uniformly dark brown like the body. Wings whitish in basal quarter, with uniformly dark brown band across the second and third quarters, a white band across the first half of the last quarter, with tip of wing brown like the median portion, posterior pair of wings banded like the anterior pair but less distinctly.

Total body-length 1·33 mm. Antennæ: length (width) i. 36 (36), ii. 45 (30), iii. 105 (30), iv. 105 (27) μ.

Head somewhat longer than wide; cheeks straight, without prominent spines.

Prothorax only slightly wider than head. Pterothorax elongate-ovate. Wings clearly narrowed in basal quarter, gradually becoming wider to near middle, distal half of wing with sides almost parallel. Sternites without depressions.

Type-material.—Male allotype (Moulton no. 2835), taken on an unknown host-plant, 20.iii.1927 (*R. E. Turner*). Holotype deposited with the British Museum.

Type-locality.—Harrismith, Orange Free State, South Africa.

The single specimen before me is distinct from other species of the genus by its broadly banded wings approaching only *R. cinctus*, Hood, from Queensland, Australia, but differing from this by the much broader median band. This species is also interesting because it is the first of the genus recorded from South Africa.

Family **Franklinothripidæ**, Bagnall, 1926.

5. *Franklinothrips megalops*, Trybom.

Nine ♀ specimens taken at Mossel Bay, Cape Province, South Africa, iv.1921 and ii. 1922 (*R. E. Turner*).

Superfamily **THRIPOIDEA**, Hood.

Family **Thripidæ**, Uzel, 1895.

Subfamily *HELIOTHRIPINÆ*, Karny.

6. *Hercothrips bicinctus*, Bagnall.

One ♀ specimen taken at Eshowe, Zululand, South Africa, v.1926 (*R. E. Turner*) (Moulton no. 2869).

For diagnosis of this genus see Hood, 'Psyche,' vol. xxxiv. no. 6, Dec. 1927.

Subfamily *SERICOTHRIPINÆ*, Karny.

7. *Sericothrips occipitalis*, Hood.

Eight female and two male specimens collected from bean-foliage, 10.iv.1922 (*A. Cuthbertson*), at the Agricultural Experiment Station, Salisbury, South Africa.

The specimens from which this species was described were found at Ibadan, Southern Nigeria, and the present record extends its distribution into South Africa.

Two specimens deposited with British Museum (Moulton, no. 1640).

8. *Scirtothrips pomeroyi*, sp. n.

Female holotype.—Colour uniformly light yellow except wings, antennal segments 1 and 3, which are whitish yellow, and distal two-thirds of 6, 7, and 8, which are greyish brown; 4 and 5 also have a shading of greyish brown on upper and lower sides of distal two-thirds. Crescents of ocelli orange-red.

Total body-length ·916 mm.; head, length ·069 mm., width across at eyes ·10 mm.; prothorax, length ·144 mm., greatest width across posterior fourth ·135 mm.; pterothorax, width ·168 mm.; abdomen, width ·21 mm. Antennæ: length (width) i. 15 (24), ii. 30 (22), iii. 33 (18), iv. 33 (18), v. 30 (18), vi. 36 (15), vii. 9, viii. 10; total length 195 μ.

Head clearly transverse, rounded in front; cheeks short, slightly converging toward the posterior. Interocellar spines small and placed almost directly in front of posterior ocelli, other head-spines inconspicuous. Eyes large, occupying more than half the length of the head. Ocelli fully developed. Mouth-cone long, pointed, reaching four-fifths across prosternum. Maxillary palpi 3-segmented. Antenna 2·8 times as long as head, segment 3 broadly clavate, 4 and 5 subovate, each with a small pedicel.

Prothorax slightly longer than greatest width and slightly more than twice as long as head, sides gradually diverging to near posterior fourth, from there converging to form broadly rounded angles. Spines on anterior angles vestigial, with a single prominent, though short, spine on each posterior angle, and a series of four small ones along posterior margin on either side. Pterothorax only slightly wider than prothorax. Sides of mesothorax broadly rounded, of metathorax straight and almost parallel. Legs normal. Wings fully developed, fore longitudinal vein fairly distinct. Spines as follows:—3—3 at base and three evenly placed over distal half, the first one being near the centre of the wing; hind vein very indistinct, but with three scattered bristles near centre of wing and one near tip where vein should be.

Abdomen elongate-ovate, with last three segments rather pointed, conical, without pubescence. Posterior margin of eighth tergite without cone. Longest spines on segments 9 and 10 approximately 75 μ, segment 10 with dorsal suture.

takes place with liberation of methane, and not of methyl chloride as stated by Beyer.

In the presence of iodine, phorone and mesityl oxide yield acetone, unchanged phorone, and acetoneanil. In the absence of iodine, condensation does not appear to occur. Under the influence of iodine and water, phorone does not appear to yield acetone. H. W.

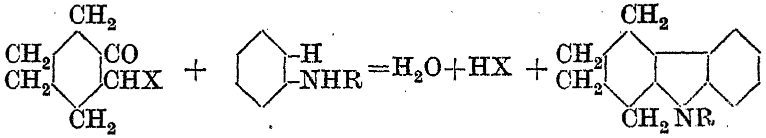
Amino-alcohols of the Quinoline Series. SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pats. 98482, 98712, and 98713; from *Chem. Zentr.*, 1923, iv, 829—830; cf. A., 1923, i, 148, 149).—6-Ethoxy-2-phenyl-4-quinolyl methyl ketone is halogenated in the methyl group and the resultant halogen derivative allowed to react with dimethylamine, diethylamine, or piperidine. The *N*-substituted 6-ethoxy-2-phenyl-4-quinolylamino-ethanone thereby obtained is then reduced to the corresponding aminoalcohol. 6-*Ethoxy*-2-*phenyl*-4-*quinolyl methyl ketone* forms yellow crystals, m. p. 107°; the *hydrochloride*, yellow crystals, has m. p. about 220° (decomp.). It is obtained by condensation of ethyl 6-ethoxy-2-phenylquinoline-4-carboxylate with ethyl acetate and elimination of carbon dioxide from the *ethyl* 6-*ethoxy*-2-*phenylquinoline*-4-*acetate*, m. p. 98—99°, thereby formed, or from 4-cyano-6-ethoxy-2-phenylquinoline by the Grignard reaction. By acting on the above-mentioned ketone with bromine in hydrobromic acid solution, 6-*ethoxy*-2-*phenyl*-4-*quinolyl bromomethyl ketone hydrochloride*, yellow crystals, m. p. 207° (decomp.), is obtained; the free *ketone* forms yellow crystals, m. p. 129°. By acting on the bromomethyl ketone with dimethylamine, 6-*ethoxy*-2-*phenyl*-4-*quinolyl dimethylaminomethyl ketone*, $OEt \cdot C_9NH_4Ph \cdot CO \cdot CH_2 \cdot NMe_2$, is obtained as the *hydrobromide*, yellow crystals, m. p. 230° (decomp.). The latter by reduction with hydrogen in the presence of a catalyst gives 6-*ethoxy*-2-*phenylquinolyl*-4-*dimethylaminoethanol*,

$$OEt \cdot C_9NH_4Ph \cdot CH(OH) \cdot CH_2 \cdot NMe_2,$$

which forms colourless, rosette-like needles, m. p. 95°; the *dihydrochloride* forms light yellow crystals, m. p. about 210° (decomp.). 6-*Ethoxy*-2-*phenyl*-4-*quinolyl diethylaminomethyl ketone monohydrobromide*, yellow crystals, m. p. about 210° (decomp.), 6-*ethoxy*-2-*phenyl*-4-*quinolyl piperidinomethyl ketone*, a yellow powder, m. p. 82° (indef.), the *hydrochloride*, m. p. about 260° (decomp.), and the *hydrobromide*, m. p. 235—240° (decomp.), of the latter are similarly obtained. The corresponding amino-alcohols are obtained by reduction. 6-*Ethoxy*-2-*phenyl*-4-*quinolyldiethylaminoethanol* forms crystals, m. p. 89° after softening; the *dihydrochloride*, yellow crystals, has m. p. 205°. 6-*Ethoxy*-2-*phenyl*-4-*quinolylpiperidinoethanol* forms colourless crystals, m. p. 110°; the *dihydrochloride*, yellow crystals, has m. p. 218°. G. W. R.

Preparation of a 2-Phenylquinolinedicarboxylic Acid. NEUMANN & Co. and J. ZELTNER (D.R.-P. 373285; from *Chem. Zentr.*, 1923, iv, 664—665).—Acetophenone-*o*-carboxylic acid, prepared, for example, from phthalic anhydride, acetic anhydride, and potassium acetate, is condensed with isatin by heating in the presence of potassium hydroxide solution at 100°. On acidifying, 2-*phenylquinoline*-4 : 7-*dicarboxylic acid* is obtained; it is a yellow, crystalline powder, m. p. 200°. G. W. R.

Preparation of Tetrahydrocarbazoles. CHEMISCHE FABRIKEN VORM. WEILER-TER MEER (D.R.-P. 374098; from *Chem. Zentr.*, 1923, iv, 724).—2-Halogen*cyclo*hexanones are condensed with primary or secondary aromatic amines, unsubstituted in the ortho-position to the amino-group. The reaction takes place in the presence of such basic substances as potassium carbonate or anhydrous potassium acetate, and is represented by



The following compounds are mentioned: tetrahydrocarbazole, from aniline and chloro*cyclo*hexanone; 3-*methyltetrahydrocarbazole*, m. p. 142°, from *o*-toluidine and chloro*cyclo*hexanone; 1-*methyltetrahydrocarbazole*, m. p. 98°, from *p*-toluidine and chloro*cyclo*hexanone; N-*ethyltetrahydrocarbazole*, a viscous oil, b. p. 220°/40 mm., from ethylaniline and 1 : 2-chloro*cyclo*hexanone. G. W. R.

Preparation of Aromatic α-Ketonic Acids. R. SÖDERQUIST (*Svensk Kem. Tidskr.*, 1922, **34**, 189—192; from *Chem. Zentr.*, 1923, iii, 1082—1083).—Aromatic α-ketonic acids are prepared by condensation of aldehydes with 4-oxo-2-thio-3-phenyloxazolidine. After oxidation and fission of the substituted oxazolidine ring, aromatic α-ketonic acids are obtained together with phenyl thiocarbimide. The condensation proceeds readily in acetic anhydride solution in the presence of anhydrous sodium acetate. Fission of the aryldihydroxyoxazolidines obtained by oxidation, takes place at the ordinary temperature on treatment with sodium ethoxide. The compounds may be separated by fractionation or by way of their hydrogen sulphite compounds. Anhydro-acids are also obtained from the elimination of a molecule of water from two ketonic acid molecules. 4-*Oxo*-2-*thio*-3-*phenyl*-5-*benzylideneoxazolidine*, from benzaldehyde and 4-oxo-2-thio-3-phenyloxazolidine, has m. p. 185—185·5°. On oxidation, it yields 2 : 4-*dihydroxy*-3-*phenyl*-5-*benzylideneoxazolidine*, m. p. 238—239°, whilst among the products of reaction with sodium ethoxide is phenylpyruvic acid. Other compounds mentioned are: 4-*oxo*-2-*thio*-3-*phenyl*-5-o-*chlorobenzylideneoxazolidine*, fine thread-like or prismatic crystals, m. p. 141·5°; 2 : 4-*dihydroxy*-3-*phenyl*-5-o-*chlorobenzylideneoxazolidine*, m. p. 152°; o-*chlorophenylpyruvic acid*, colourless leaflets, m. p. 145° (m. p. 152—152·5° when heated quickly); *semicarbazone* of the latter, m. p. 167·5°; *phenylhydrazone*, m. p. 141°; 4-*oxo*-2-*thio*-3-*phenyl*-5-m-*chlorobenzylideneoxazolidine*, light yellow prisms, m. p. 192°; m-*chlorophenylpyruvic acid*, prisms; semicarbazone of the latter, m. p. 176°; *phenylhydrazone*, m. p. 141°; 4-*oxo*-2-*thio*-3-*phenyl*-5-p-*chlorobenzylideneoxazolidine*, m. p. 237—237·5°; p-*chlorophenylpyruvic acid*, platelets; *semicarbazone* of the latter,

m. p. 184°; *phenylhydrazone*, m. p. 164°; *4-oxo-2-thio-3-phenyl-5-(3′ : 4′)methylenedioxybenzylideneoxazolidine*, m. p. 240° 2 : 4-*methylenedioxyphenylpyruvic acid*, colourless leaflets; *semicarbazone* of the latter, m. p. 197°; *phenylhydrazone*, m. p. 144° 4-*oxo-2-thio-3-phenyl-5-*m-*nitrobenzylideneoxazolidine*, m. p. 207° 4-*oxo-2-thio-3-phenyl-5-*o-*acetoxybenzylideneoxazolidine*, yellow prisms, m. p. 162·5—163°. G. W. R.

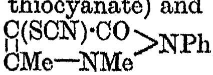
Action of Hydroxylamine and of Hydrazine on the Aryl Monothioamides of Carbethoxyethylmalonate. D. E. Worrall (*J. Amer. Chem. Soc.*, 1923, **45**, 3092—3095; cf. A., 1922, i, 874).—*iso*Oxazoles and pyrazoles were obtained by the action of hydroxylamine and hydrazine, respectively, on carbethoxyethylmalonate monothioamides. Thus carbethoxyethylmalonate monothioanilide gave *ethyl* 3-*anilino*-5-*oxo*-iso*oxazole*-4-*carboxylate*, small needles, m. p. 166°, and the corresponding *pyrazole* ester, fluffy, white needles, m. p. 194—195°. *Ethyl* 3-o-*toluidino*-5-iso-*oxazole*-4-*carboxylate*, flat needles, m. p. 165—167° (decomp.), and the corresponding *pyrazole* ester, white needles, m. p. 215° (decomp.); *ethyl* 3-p-*toluidino*-5-*oxo*iso*oxazole*-4-*carboxylate*, needles and plates, m. p. 172—173° (decomp.), and the corresponding *pyrazole* ester, feathery needles, decomp. above 200°; *ethyl* 3-p-*bromoanilino*-5-*oxo*iso*oxazole*-4-*carboxylate*, slender needles, m. p. 163—170° (decomp.), and the corresponding *pyrazole* ester, needles, m. p. 217°, were obtained. F. B.

4′-Amino-1-phenyl-5-methylbenzthiazole and its Bromination in Glacial Acetic Acid. The Dibromo-product of Gatterman. The Fluorescence of some Benzthiazoles. R. F. Hunter (*Chem. News*, 1923, **127**, 385—386).—An alcoholic solution of dehydrothiotoluidine (4′-amino-1-phenyl-5-methylbenzthiazole) exhibits a green fluorescence in the light of a mercury lamp; its dibromide shows a blue fluorescence in glacial acetic acid solution, and the acetyl derivative is also strongly fluorescent. The dibromide is decomposed by nitrous acid and consequently cannot be diazotised. E. H. R.

Absorption Colours of the Second Order. J. Piccard and F. de Montmollin (*Helv. Chim. Acta*, 1923, **6**, 1011—1019).—It was shown previously that *meri*-quinonoid salts of tetraphenylbenzidine have a yellow colour of the second order (A., 1913, i, 895). It is now shown that Nietzki's rule also applies to such second order colours; the second absorption band can be moved further into the visible spectrum by increasing the molecular weight, changing the colour of the compound from yellow to red. This has been demonstrated by preparing a *meri*-quinonoid salt of diphenyldi-*p*-diphenylylbenzidine, $C_6H_4Ph·NPh·C_6H_4·C_6H_4·NPh·C_6H_4Ph$. *Diphenyl*-p-*diphenylylamine*, $C_6H_4Ph·NPh_2$, is formed by heating diphenylamine with *p*-iododiphenyl in nitrobenzene in presence of potassium carbonate and a little copper; it forms long, nearly colourless crystals, m. p. 114°. It forms a yellowish-green compound with chloranil, and gives a greenish-blue coloration with concentrated sulphuric acid. When oxidised in glacial acetic acid with sodium dichromate, it gives a red colour, changing to green; the green solution is reduced with zinc dust and from the diluted solution *diphenyldidiphenylylbenzidine* can be extracted with chloroform, in 20% yield. It forms a brown powder, m. p. 135—140°. The same substance can be obtained in an impure form by condensing *s*-diphenylbenzidine with *p*-iododiphenyl. All solutions of the compound show a strong violet fluorescence which is excited by ultra-violet light at the limit of the visible spectrum. This benzidine derivative is oxidised by sodium dichromate in glacial acetic acid solution into a *meri*-quinonoid salt which can be precipitated by picric acid as meri-*diphenyldi*-p-*diphenylyldiphenoquinonedi-immonium picrate*, a red powder. Further oxidation gives the green *holo*-quinonoid salt. E. H. R.

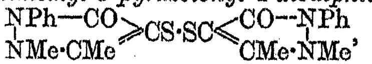
Additive Reactions of Thiocyanogen. H. P. Kaufmann and J. Liepe (*Ber.*, 1923, **56**, [*B*], 2514—2520).—Attempts have been made to estimate enols by titration with solutions of thiocyanogen in the hope of thereby avoiding secondary disturbances such as may be caused by the liberated hydrogen bromide in Meyer's bromine titration method. It is found, however, that the reagent can be applied only under definite conditions; in general applicability and rapidity of execution, the method is not equal to Meyer's process. Quantitative experiments with solutions of thiocyanogen are rendered very difficult on account of the ease with which it becomes polymerised, particularly on exposure to sunlight or to an elevated temperature.

Thiocyanogen reacts with antipyrine in the presence of chloroform to give a mixture of *antipyrine thiocyanate*, colourless, lustrous needles, m. p. 125° (which is also obtained from antipyrine sulphate and potassium thiocyanate) and 4-*thiocyano*-1-*phenyl*-2 : 3-*dimethyl-pyrazol*-5-*one*,



$\begin{matrix}\mathrm{C(SCN){\cdot}CO}\\ \| \\ \mathrm{CMe{-}NMe}\end{matrix}\!\!>\!\mathrm{NPh}$

, colourless crystals, m. p. 147—148°; the constitution of the latter substance follows from its preparation from 4-bromoantipyrine and potassium thiocyanate in boiling aqueous solution. 4-*Thiocyanoantipyrine thiocyanate* has m. p. 84°. 4-Thiocyanoantipyrine is very readily hydrolysed by alkali hydroxide to potassium cyanide, potassium cyanate, and *bis*-1-*phenyl*-2 : 3-*dimethyl*-5-*pyrazolonyl* 4-*disulphide*,



$$\begin{matrix}\mathrm{NPh{-}CO}\\ | \\ \mathrm{NMe{\cdot}CMe}\end{matrix}\!\!>\!\mathrm{CS{\cdot}SC}\!<\!\!\begin{matrix}\mathrm{CO{-}NPh}\\ | \\ \mathrm{CMe{\cdot}NMe}\end{matrix},$$

very pale yellow, hexagonal plates, m. p. 256°; the compound can also be prepared by means of aqueous alcohol. 4-Thiocyanoantipyrine is reduced by zinc and hydrochloric acid in the presence of alcohol to the additive *compound* of zinc chloride and 4-thiolantipyrine, $C_{11}H_{12}ON_2S,ZnCl_2$, a white precipitate from which the thiol could not be isolated.

[With M. Thomas.]—Addition and substitution of free thiocyanogen occur much more slowly than in the case of bromine. Thus ethyl hydrocollidinedicarboxylate reacts with seven atomic proportions of chlorine and four of bromine, but not with iodine; with thiocyanogen, it gives a *di-thiocyano*-derivative, $C_{16}H_{19}O_4N_3S_2$, m. p. 115° (decomp.). *Ethyl collidinedicarboxylate thiocyanate* crystallises in colourless, monoclinic plates, m. p. 133°.

[With M. Thomas.]—Reactions with free cyanogen depend greatly on the solvent used, addition occurring particularly rapidly in the presence of nitromethane (as example of a solvent of high dissociating power). The action of sunlight and of certain catalysts, notably iron, is advantageous. Thus, whereas salicylic acid is indifferent towards thiocyanogen under the usual conditions, it is converted in nitromethane solution in the presence of iron powder into 2-*hydroxy-5-thiocyanobenzoic acid*, monoclinic leaflets, m. p. 167—168°.

H. W.

New Methods of Splitting Pyrimidines. II. Decomposition of Pyrimidines by means of Ferrous Salts. M. H. Pfaltz and O. Baudisch (*J. Amer. Chem. Soc.*, 1923, **45**, 2972—2980; cf. A., 1921, ii, 337).—The splitting of pyrimidines under conditions closely resembling those in the metabolism of plants and animals was accomplished by the action of the system ferrous sulphate–sodium hydrogen carbonate–air and the system sodium pentacyanoaquoferroate–oxygen or air (A., 1900, i, 591) on uracil and thymine. In each case the pyrimidine ring was partly hydrolysed, with the formation of highly coloured intermediate substances which were completely hydrolysed by warm sodium hydrogen carbonate with the production of carbamide. The action was retarded by hydrogenation of the pyrimidine ring as in hydrouracil and by the presence of a methyl group in the 5-position as in thymine, and by the addition of any substance possessing a strong affinity for iron, *e.g.*, ammonia, potassium cyanide. F. B.

5-Benzoylbarbituric Acids. H. Biltz and T. Köhler (*Ber.*, 1923, **56**, [*B*], 2482—2489).—In continuation of the work on 5-acylbarbituric acid (cf. Biltz and Wittek, A., 1921, i, 454), 5-benzoylbarbituric acid has been examined in detail. The position of the benzoyl group is placed beyond doubt by the observed ketonic properties of the compound, by the existence of similar derivatives of 1 : 3-dimethyl- and 1 : 3-diethyl-barbituric acids, and by the inability of alkalis to effect hydrolysis.

5-Benzoylbarbituric acid,

$CO<\substack{NH\cdot CO\\NH\cdot CO}>CHBz$, pale yellow aggregates of prisms, m. p. 275° (decomp.), is prepared by heating barbituric acid with benzoic anhydride at 175° during five hours; it cannot be prepared from barbituric acid, benzoyl chloride, and sodium hydroxide or from barbituric and benzoic acids. The *potassium* salt, rhombic leaflets, decomp. about 315°, is described. It is stable towards sodium hydroxide solution or concentrated hydrochloric acid. It is decomposed by hot fuming nitric acid into alloxan and benzoic or nitrobenzoic acids, and by bromine in aqueous solution at the atmospheric temperature into benzoic and 5 : 5-dibromobarbituric acids. It gives a *hydrazone*, $C_{11}H_{10}O_3N_4$, slender, pale yellow needles, decomp. 260°, and a *phenylhydrazone*, $C_{17}H_{14}O_3N_4$, small, pale yellow needles, decomp. 218°; a semicarbazone could not be obtained. It is decomposed by thiosemicarbazide in boiling aqueous-alcoholic solution into barbituric acid and 2-amino-5-phenylthiodiazole (cf. Young and Eyre, T., 1901, **79**, 57); 5-acetylbarbituric acid yields, in a similar manner, barbituric acid and 5-amino-2-methylthiodiazole. The action of hydroxylamine on 5-benzoylbarbituric acid in boiling alcoholic solution gives a *substance*, colourless, lustrous, hexagonal platelets, m. p. 261°, which is regarded as the oxime of 5-amino-5-benzoylbarbituric acid, $CO<\begin{matrix}NH\cdot CO\\NH\cdot CO\end{matrix}>C(NH_2)\cdot CPh:N\cdot OH$; it is converted by hot, concentrated nitric acid into alloxan, by highly concentrated hydriodic acid into benzoylbarbituric acid, and by bromine water into alloxan and benzaldehyde. 5-Benzoylbarbituric acid is converted by sodium hydroxide and methyl sulphate into the *methyl ether* of the enolic form of 5-benzoylbarbituric acid, $CO<\begin{matrix}NH\text{——}CO\\NH\cdot C(OMe)\end{matrix}\geqslant CBz$, colourless, lustrous prisms, decomp. 105°; the corresponding *phenylhydrazone*, $C_{18}H_{16}O_3N_4$, decomp. 225°, is described. The ethylation of 5-benzoylbarbituric acid could not be effected by ethyl sulphate or ethyl bromide, magnesium oxide, and carbon tetrachloride at 140°.

1-Methylbarbituric acid and benzoic anhydride react at 130—140° to give 5-*benzoyl*-1-*methylbarbituric acid*, small, pale brown prisms, decomp. 225° (*phenylhydrazone*, slender, yellow needles, decomp. 205°). 5-*Benzoyl*-1-*ethylbarbituric acid*, flattened prisms, m. p. 205° (decomp.), and its *phenylhydrazone*, slender needles, decomp. 190° after darkening at 175°, are described. 1 : 3-Dimethylbarbituric acid reacts with benzoic anhydride at 130°, but the expected 5-benzoyl-1 : 3-dimethylbarbituric acid could not be isolated from the product of the reaction in the homogeneous condition; it is characterised as the *phenylhydrazone*, $C_{19}H_{18}O_3N_4$, colourless, quadratic leaflets, decomp. 218°. 5-Benzoyl-1 : 3-diethylbarbituric acid could not be caused to crystallise; the *phenylhydrazone*, $C_{21}H_{22}O_3N_4$, forms long, yellow leaflets, decomp. 164°.

Attempts to cause interaction between barbituric acid and oxalic acid, oxalyl chloride, oxalyl bromide, or phthalic anhydride were not successful. Thiobarbituric acid does not react smoothly with acetic or benzoic anhydrides. The acetyl group of 5-acetylbarbituric acids does not appear to be capable of condensing with aldehydes. H. W.

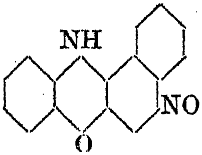
Alkyl*iso*propylbarbituric Acids. F. HOFFMANN LA ROCHE & Co. (Austr. Pat. 92386; from *Chem. Zentr.*, 1923, iv, 665).—In modification of an earlier patent (A., 1922, i, 872) other alkyl halides are used in place of allyl bromide. 5-*Methyl*-5-*isopropylbarbituric acid*, from *iso*propylbarbituric acid and methyl iodide, forms crystals, m. p. 186—187°. 5 : 5-*Diisopropylbarbituric acid* forms crystals, m. p. above 230° (decomp.). G. W. R.

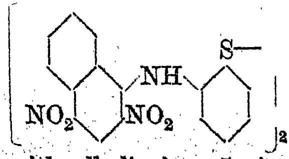
Preparation of New Barbituric Acid Compounds. CHEMISCHE FABRIK AUF AKTIEN, VORM. E. SCHERING (Brit. Pat. 198379; addn. to 158558; cf. A., 1922, i, 582).—New compounds, similar in properties to that previously described (*loc. cit.*) are obtained by replacing the diethylbarbituric acid in the original process by dipropyl-, diallyl-, or phenylethyl-barbituric acid. The products of these three fusions melt respectively at 82—86°, 85—88°, and 106—120°. W. T. K. B.

Diketopiperazine Derivatives. P. Karrer, C. Gränacher, and A. Schlosser (*Helv. Chim. Acta*, 1923, **6**, 1108—1112).—Benzyl chloride reacts with the silver salt of glycine anhydride to give 2 : 5-*dihydroxydihydropyrazine dibenzyl ether*, crystallising in white leaflets, m. p. 164°. The reaction therefore follows a different course from that of methyl iodide on the anhydride (A., 1922, i, 235). The new compound is readily hydrolysed by boiling dilute acids to benzyl alcohol and glycine, and in this respect differs markedly from its isomerides, *N* : *N'*-dibenzylglycine anhydride and diketo-2 : 5-dibenzylpiperazine. E. H. R.

New Syntheses in the Quinoneimide Dye Group. I. Syntheses with 1-Chloro-2 : 4-dinitronaphthalene. F. Kehrmann (with A. van Baerle) (*Ber.*, 1923, **56**, [*B*], 2385—2390).—A number of known and some new quinoneimide dyes have been prepared by condensing 1-chloro-2 : 4-dinitronaphthalene with different bases. In many cases the toluene-*p*-sulphonic ester of Martius's yellow (2 : 4-dinitro-α-naphthol) can also be used.

o-2 : 4-*Dinitronaphthylaminodiphenylamine* is obtained by condensing the dinitrochloronaphthalene with *o*-aminodiphenylamine in alcohol; it forms large, brownish-red prisms containing benzene from that solvent, which lose benzene and turn black at 70°, m. p. 140°. With 5-chloro-2-aminodiphenylamine, the corresponding 5-*chloro*-2-(2 : 4-*dinitronaphthylamino*)*diphenylamine* is obtained, dark brown leaves, m. p. 110°. Both these compounds are reduced smoothly by stannous chloride to rosinduline and chlororosinduline respectively. The rosindones are obtained by fusing the dinitro-compound with benzoic acid.

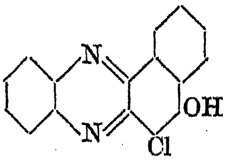




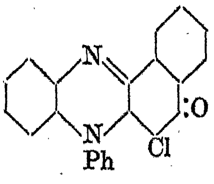
By condensing 2 : 4-dinitro-1-naphthyltoluenesulphonate with *o*-aminophenol, *o*-2 : 4-dinitronaphthylaminophenol is obtained which, by careful treatment with aqueous sodium hydroxide is converted into 5-*nitro*-7 : 12-*naphthaphenoxazine* (annexed formula), a violet precipitate which decomposes when heated. An acetyl derivative could not be obtained, but instead the known phenonaphthoxazone was formed. With *oo'*-diaminodiphenyl disulphide the above toluenesulphonate condenses to give o-*bis*-2 : 4-*dinitronaphthylaminophenyl disulphide* (annexed formula), orange-yellow leaflets, m. p. 169°. With *o*-aminothiophenol it gives o-2 : 4-*dinitronaphthylaminophenyl mercaptan*, a lemon-yellow, crystalline powder, m. p. 198°, which by careful treatment with alkali gives 5-*nitro*-7 : 12-*naphthaphenthiazine*, nearly black needles with a brassy reflex, m. p. 156° (decomp). It is much more stable than the corresponding oxazine. A by-product of the last condensation, yellow, glistening crystals, m. p. 150°, appeared to be 2 : 4-*dinitronaphthyl*-o-*aminophenyl sulphide*.

E. H. R.

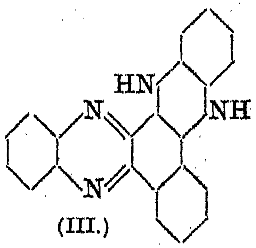
New Syntheses in the Quinoneimide Dye Group. II. Steric Influence in the Condensation of Hydroxyquinones with *o*-Diamines. F. Kehrmann [with C. Buffat] (*Ber.*, 1923, 56, [*B*], 2390—2394).—It has long been known that substituted quinones such as chloranilic acid and 3-chloro-4-hydroxy-1 : 2-naphthaquinone react with difficulty or not at all with *o*-diamines, but it is now found that these reactions proceed under suitable conditions. Thus when chloranilic acid is heated with *o*-phenylenediamine hydrochloride and a large quantity of benzoic acid at the boiling point, 1 : 4-*dichloro*-2 : 3-*dihydroxyphenazine* is formed, dark brownish-red, metallic crystals, blackening at 310°. It gives a dichroic sulphuric acid solution, brown in thick, greenish-yellow in thin layers. With *o*-aminodiphenylamine, chloranilic acid gives 1 : 4-*dichloro-2-hydroxy*apo*safranone*, dark, reddish-brown crystals with a weak, brassy lustre, decomposing at 285°. 3-Chloro-4-hydroxy-1 : 2-naphthaquinone with *o*-phenylenediamine gives 6-*chloro*-5-*hydroxy*-αβ-*naphthaphenazine* (formula I), dark red, brassy crystals decomposing at about 280°. It gives a dirty yellowish-green colour with concentrated sulphuric acid, ponceau-red with hot alkali. With *o*-aminodiphenylamine, 3-chloro-2-hydroxy-1:4-naphthaquinone gives 6-*chlororosindone* (formula II), red needles with golden lustre, m. p. 255°, giving a dark yellowish-green colour in sulphuric acid. With 2-amino-5-chlorodiphenylamine, 6 : 9-*dichlororosindone* is formed, red needles with strong gold reflex, m. p. 242—243°, giving a dirty violet-red colour in sulphuric acid.



(I.)



(II.)

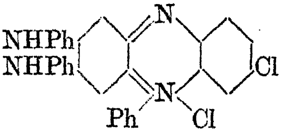


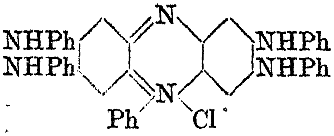
(III.)

When the above 5-hydroxy-6-chloronaphthaphenazine is fused with *o*-phenylenediamine, a new *dihydronaphthadiphenazine* (formula III) is formed, golden-yellow leaflets with brassy reflex, m. p. 263°. Its *hydrochloride* forms dark red, metallic needles, and it gives a pure green colour in concentrated sulphuric acid.

E. H. R.

New Syntheses in the Quinoneimide Dye Group. III. Syntheses of Induline-3*B* and -6*B*. F. Kehrmann [with W. Klopfenstein] (*Ber.*, 1923, 56, [*B*], 2394—2397).—The constitutional formulæ assigned to Induline-3*B* and -6*B* have now been confirmed by synthesis of these dyes from dianilino-*o*-quinone,  When this is condensed with 2-amino-5-chlorodiphenylamine hydrochloride in alcohol, 3-*chloro*-8-*anilinophenyl*aposafranine (annexed formula) is formed, crystallising in needles with a green reflex. The free *base* forms brownish-red needles, m. p. 258°. The colour in concentrated sulphuric acid is violet-blue, becoming violet and then Bordeaux-red on dilution. When this is boiled with aniline and aniline hydrochloride, the ring chlorine is replaced by the anilino-group, forming 8-*anilino*-3 : 7-*diphenylphenosafranine*, identical with Induline-3*B*. The free base forms nearly black leaflets with a weak green reflex, m. p. 242°. Induline-3*B* is converted into Induline-6*B*, 2 : 8-dianilino-3 : 7-diphenylphenosafranine (annexed formula), by boiling with aniline and aniline hydrochloride in presence of 1 mol. of mercuric oxide. The free base forms greenish-black metallic crystals, m. p. 286—288°; the *hydrochloride* and *hydrobromide* both form crystals with a coppery lustre, insoluble in water.

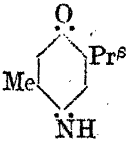




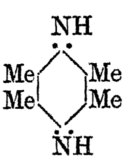
E. H. R.

New Syntheses in the Quinoneimide Dye Group. IV. The Colour of the Simple Quinoneimines. F. Kehrmann [with B. Cordone] (*Ber.*, 1923, 56, [*B*], 2398—2405).

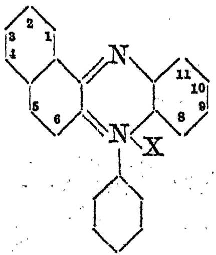
—In a previous paper (A., 1922, ii, 333), the rule was established that the effect of salt formation on the colour of basic nitrogen compounds is to intensify the colour if the unsaturated condition persists. This rule has now been found to apply to compounds of the quinoneimine series, of which several new members have been prepared. *Thymoquinonemonoimine* (annexed formula) was prepared by oxidising *p*-aminothymol with silver oxide in ethereal solution; it crystallises in bright yellow, silky leaflets, m. p. 74—75°. It is stable for some time in the dark at low temperatures and is much less sensitive to light than *p*-benzoquinonemonoimine. Its salts are deeper yellow in colour than the compound itself; the *hydrochloride* is obtained as a voluminous, yellow precipitate from ether; the *picrate*, which is stable for some time in water, forms bright yellow, sparingly soluble crystals. The monoimines of benzo- and tolu-quinone were prepared afresh to confirm their yellow colour. Benzoquinonechloroimine, O::NCl, is also yellow, but benzoquinonedi-imine is colourless, whilst its dihydrochloride is yellow. Benzoquinonedichlorodi-imine, ClN::NCl, is colourless; it



gives a salt only with concentrated sulphuric acid, and this is yellow. *Duroquinonedi-imine* (annexed formula) was obtained by oxidising diaminodurene with silver oxide in ether; it forms colourless crystals, not very sensitive to light, m. p. 134—135°. It dissolves in dilute mineral acids, giving bright yellow solutions which soon decompose with deposition of duroquinone. The salts, which can be obtained in crystalline form from ether, are bright yellow. The results show that the carbonyl group is a stronger chromophore than the iminocarbonyl group $\cdot C{:}NH$. This is also shown by the fact that whilst tetramethyldiaminobenzophenone is yellow, auramine base is colourless. E. H. R.



Determination of the Constitutional Formulæ of Colouring Matters from their Absorption Spectra. V. F. Kehrmann and M. Sandoz (*Helv. Chim. Acta*, 1923, **6**, 982—994).—The absorption spectra of the mono-acid and di-acid salts of phenyl-αβ-benzophenazonium (annexed formula) and of the mono-, di-, and tri-acid salts of nine of its monoamino-derivatives have been measured. The mono-salt of the parent substance is yellow with orange fluorescence, the di-salt violet; both have an ortho-quinonoid structure. The amino derivatives, 1-, 2-, 3-, and 4- form a group. Their mono-salts are bluish-green, except that of the 3-amino-derivative, which is brown; their di-salts are yellow, similar to the mono-salt of the parent substance, and their tri-salts deep red, comparable with the di-salt of the parent. The 1-amino-compound does not form a tri-salt, probably on account of steric hindrance. All these salts are given an ortho-quinonoid structure. The mono-salt of the 10-amino-derivative (violet) is probably also ortho-quinonoid. The 9- and 5-amino-compounds form another group; they behave similarly to *apo*safranine (A., 1920, ii, 142). The mono-acid salt (scarlet) and the di-acid salt (green) are para-quinonoid, whilst the tri-acid salt (violet) has the ortho-quinonoid structure. The fact that the di-acid salts can be diazotised indicates that the solutions contain a small amount of the yellow, ortho-quinonoid di-acid salt in equilibrium with the para-quinonoid form. Two amino-derivatives, the meta- and para-, were prepared having the amino-group in the external benzene ring. Here the auxochromic effect of the amino-group is reduced to a minimum, and there is little difference between the colours of the mono-acid salt and of the di-acid salt, both being yellow in solution; the tri-acid salt is violet, and all three are ortho-quinonoid. Curves are given showing the absorption spectra of all the salts examined. E. H. R.



Spirans. XII. Heterocyclic Dispirans and the Nature of the Basic Properties of the Imino-group. D. Radulescu (*Bul. Soc. Ştiinţe Cluj*, 1922, **1**, 356—360; from *Chem. Zentr.*, 1923, iii, 1081; cf. this vol., i, 58).—Heterocyclic dispirans have been prepared by the author by the action of *o*-diamines on dichlorobisdiketohydrindene (I). *Piperazinebis*-3-1 : 3-*diketohydrindene*-2 : 2 : 3 : 2-*dispiran*, $C_{20}H_{14}O_4N_2$, (II) forms yellow prisms, m. p. 249° (corr.). The *spiran* (III), $C_{24}H_{14}O_4N_2$, forms microcrystalline brown prisms, m. p. 272° (corr.). Spiran III is scarcely basic, whilst the dispiran II is moderately basic. This is explained by Thiele's theory of partial valencies, which is also applicable to the slight basicity of pyrrole and indole. Spirans with tertiary nitrogen are more basic. N : N′-*Dipiperidylbis*-1 : 3-*diketohydrindene* (IV) forms orange prisms, m. p. 174°. The *diethylamino*-derivative of the latter forms yellow prisms, m. p. 129°, and the *dibenzylamino*-derivative yellow needles, m. p. 178°. The author concludes that the hydroxy-derivatives corresponding with the amines must be strongly acid. The compound described by Gabriel and Leupold (A., 1898, i, 481) as bisdiketohydrindene oxide (V) is really a spiran pinacone (VI). It is hydrolysed by weak acids and alkalis to diketohydrindene, and its decomposition products, and phthalonic acid.

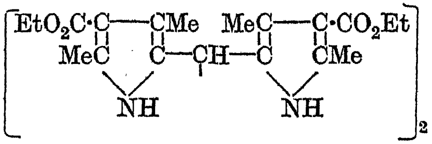
G. W. R.

Reactions of certain Substituted Guanidines with Sulphur. G. Bruni and T. G. Levi (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 313—316).—When heated together in a sealed tube at 260—270°, *s*-diphenylguanidine and sulphur give a good yield of mercaptobenzthiazole. In aniline solution, subjected to prolonged boiling in a reflux apparatus, the reaction gives rise to little or no mercaptobenzthiazole, but to anilinobenzthiazole (cf. Hofmann, A., 1880, 388; Jacobson and Frankenbacher, A., 1891, 1048; Hugershoff, A., 1903, i, 865; and Rassow and Döhle, A., 1916, i, 747): $NHPh{\cdot}C(:NH){\cdot}NHPh+S=C_6H_4{<}\overset{N}{\underset{S}{}}{>}C{\cdot}NHPh+NH_3$; the *acetyl* derivative of anilinobenzthiazole has m. p. 162—163°.

Mercaptobenzthiazole is formed in good yield when phenylguanidine, and in poor yield when *s*-triphenylguanidine, is heated in a sealed tube with sulphur at 270° (cf. Sebrell and Bord, this vol., i, 89). T. H. P.

Tetrapyrrlethanes. I. HANS FISCHER and M. SCHUBERT (*Ber.*, 1923, **56**, [*B*], 2379—2384; cf. A., 1923, i, 707).—Glyoxal can be condensed with ethyl 2 : 4-dimethylpyrrole-3-carboxylate in alkaline or, better, in acid alcoholic solution, to form *tetra*(*3-carbethoxy-2 : 4-dimethyl-5-pyrryl*)*ethane* (annexed formula), which crystallises in colourless leaflets, m. p. 282°. It gives an intense green solution in acetic acid. Oxidation with ferric chloride gives 2 mols. of bis-2 : 4-dimethyl-3-carbethoxypyrrylmethene, whilst reduction with hydriodic acid in acetic acid solution gives a mixture of pyrroles containing 2 : 4-dimethyl- and 2 : 4 : 5-trimethyl-pyrrole. Potassium methoxide converts the ethane compound into tetramethylpyrrole. It can also be hydrolysed to *tetra*(*3-carboxy-2 : 4-dimethylpyrryl*)*ethane*, small tetrahedral crystals, m. p. 233° (decomp.), but this product is not identical with that obtained by condensing glyoxal with 2 : 4-dimethylpyrrole-3-carboxylic acid.



The relationship of tetrapyrrylethane derivatives with blood- and bile-pigments is discussed, the conclusion being that there is a closer relationship with the latter. This conclusion is supported by spectroscopic examination of copper and zinc salts of a number of dipyrrylmethene derivatives. E. H. R.

Diallylxanthine. SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pat. 97978; from *Chem. Zentr.*, 1923, iv, 830).—By heating 4 : 5-*diamino*-2 : 6-*dioxo*-1 : 3-*diallylpyrimidine*, obtained by condensation of diallylcarbamide with cyanoacetic acid or ethyl cyanoacetate, treatment with nitrous acid, and reduction with formic acid, 5-*formylamino*-4-*amino*-2 : 6-*dioxo*-1 : 3-*diallylpyrimidine* is obtained. This is heated with *N* sodium hydroxide solution at 100° and then acidified, whereby 1 : 3-*diallylxanthine*, m. p. 155—156°, is obtained. The intermediate compound, 4-*amino*-6-*oxo*-5-*oximino*-1 : 3-*diallylpyrimidine*, can also be obtained by direct condensation of *s*-diallylcarbamide with ethyl oximinocyanoacetate. G. W. R.

1 : 3 : 7-Triallylxanthine. SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pat. 97979; from *Chem. Zentr.*, 1923, iv, 830; cf. preceding abstract).—1 : 3-*Diallylxanthine* is alkylated, for example by treatment with allyl benzoate in the presence of ethyl-alcoholic potassium hydroxide at 80°. 1 : 3 : 7-*Triallylxanthine* has m. p. 57—58°; b. p. 176°/5 mm. G. W. R.

Oxidation of Uric Acid with Ferrous Salts. I. M. H. PFALTZ (*J. Amer. Chem. Soc.*, 1923, **45**, 2980—2984; cf. this vol., i, 210).—Cleavage of the uric acid molecule was accomplished by the systems ferrous sulphate–sodium hydrogen carbonate–air and sodium pentacyanoaquoferroate–air or oxygen, but not by the system ferrous sulphate–oxygen. The action was similar to that which occurred with pyrimidines. F. B.

Action of Alkali on Substituted Uric Acids. I. 9-Phenyl-1 : 3-dimethyluric Acid. E. S. GATEWOOD (*J. Amer. Chem. Soc.*, 1923, **45**, 3056—3064; cf. A., 1923, i, 253).—This substituted uric acid was decomposed instantaneously at 100° with 4*N* sodium hydroxide with the elimination of methylamine. On acidifying the solution, carbon dioxide was evolved, and crystals, m. p. 249—250°, of 3-*phenyl*iso*hydantoin-5-carboxyl*-o-*methylamide* separated. This was further decomposed by alkali into phenylcarbamide, methylamine, oxalic acid, and formic acid, whilst oxidation with hydrogen peroxide in alkaline solution yielded *5-hydroxy-3-phenylhydantoin 5-carboxyl*-o-*methylamide*, large, thin, rectangular plates, m. p. 195—196°. This was further decomposed by alkali into methylamine, phenylcarbamide, and meso-oxalic acid. 9-*Phenyl*-1 : 7-*dimethyluric acid* was synthesised. It did not melt below 280° and was not affected by boiling with 4*N* sodium hydroxide for ten minutes. F. B.

The Activation of Halogen and Methyl in Aromatic Compounds by the Azo-group, ·N:NR. W. BORSCHE and I. EXSS (*Ber.*, 1923, **56**, [*B*], 2353—2357).—Experiments with 4-chloro-3-nitroazobenzene and 6-chloro-3-nitro-4′-methoxyazobenzene, show that the azo-group in ortho- or para-position to the halogen imparts to it increased activity. These compounds react more readily with hydrazine, ammonia, aniline, or sodium ethoxide than *o*- or *p*-chloronitrobenzene, although not so readily as chloro-2 : 4-dinitrobenzene. On the other hand, benzeneazo-2-nitro-*p*-toluene does not react with benzaldehyde to form a stilbene derivative as does 2 : 4-dinitrotoluene.

4-Chloro-3-nitroazobenzene, from 4-chloro-3-nitroaniline and nitrosobenzene, forms brown needles, m. p. 84°. *6-Chloro-3-nitro-4′-hydroxyazobenzene*, from diazotised 6-chloro-3-nitroaniline and phenol, forms red needles, m. p. 218°; it is methylated by methyl sulphate to *6-chloro-3-nitro-4′-methoxyazobenzene*, deep yellow leaflets, m. p. 103°. *Benzeneazo-2-nitro*-p-*toluene*, from 2-nitro-*p*-toluidine and nitrosobenzene, forms brown needles, m. p. 106°.

3-Nitro-4-hydrazinoazobenzene, $Ph{\cdot}N_2{\cdot}C_6H_3(NO_2){\cdot}NH{\cdot}NH_2$, forms red needles, m. p. 206° (decomp.); with acetophenone it forms the corresponding *hydrazone*, $Ph{\cdot}N_2{\cdot}C_6H_3(NO_2){\cdot}NH{\cdot}N{:}CMePh$, red needles, m. p. 195°. *2-Nitro-4-benzeneazo-4′-hydroxyazobenzene*, $Ph{\cdot}N_2{\cdot}C_6H_3(NO_2){\cdot}N_2{\cdot}C_6H_4{\cdot}OH$, obtained from the above hydrazine and *p*-benzoquinone, forms brown needles, m. p. 203° (decomp.); with quinoneoxime, the hydrazine forms an *oximehydrazone*, $Ph{\cdot}N_2{\cdot}C_6H_3(NO_2){\cdot}NH{\cdot}N{:}C_6H_4{:}N{\cdot}OH$, a red, crystalline powder, m. p. 235° (decomp.).

3-Nitro-4-aminoazobenzene forms red needles, m. p. 173·5°. *3-Nitro-4-piperidinoazobenzene*, by condensing 4-chloro-3-nitroazobenzene with piperidine, forms orange-red tablets, m. p. 64°. *3-Nitro-4-anilinoazobenzene*, $Ph{\cdot}N_2{\cdot}C_6H_3(NO_2){\cdot}NHPh$, forms brown needles,

m. p. 124°. 3-*Nitro-4-methoxyazobenzene* crystallises in orange-red needles, m. p. 107°.

3-*Nitro-4'-methoxy-6-hydrazinoazobenzene* forms red needles, m. p. 173°; with *p*-anisaldehyde it gives the corresponding *hydrazone*, red needles, m. p. 208°. 5-*Nitro-2-amino-4'-methoxyazobenzene* forms brownish-yellow needles, m. p. 136°. 3-*Nitro-6 : 4'-dimethoxyazobenzene* forms orange-yellow needles, m. p. 123°. E. H. R.

Thiophenols. V. Salts and Additive Compounds of *oo'*-Azophenyl Methyl Sulphide and *oo'*-Azoxyphenyl Methyl Sulphide. K. BRAND and P. GROBEL (*Ber.*, 1923, **56**, [*B*], 2563—2567).—An extension of the work of Brand and Wirsing (A., 1912, i, 666; 1913, i, 406) on the para-compounds to the ortho-series.

The following salts of *oo'*-dimethylthiolazobenzene,

$$SMe\cdot C_6H_4\cdot N{:}N\cdot C_6H_4\cdot SMe,$$

are described: the *perchlorate*, $C_{14}H_{14}N_2S_2,HClO_4$, bluish-violet needles which are very sensitive to moisture, m. p. 154°; the *sulphate*, $C_{14}H_{14}N_2S_2,2H_2SO_4$, dark violet needles; the very unstable *hydrochloride*, blue needles, and its additive *compounds* with stannic chloride, $C_{14}H_{14}N_2S_2,HCl,SnCl_4$, blackish-violet needles, with ferric chloride, $C_{14}H_{14}N_2S_2,HCl,FeCl_3$, dark violet, almost black needles, and mercuric chloride, an unstable, blue compound.

oo'-Dimethylthiolazobenzene is transformed by methyl sulphate into the *methosulphate*, $N_2(C_6H_4\cdot SMe_2\cdot O\cdot SO_2\cdot OMe)_2$, coarse crystals, m. p. 189° (decomp.), which is converted into the corresponding *iodide*, $C_{14}H_{14}N_2S_2,2MeI$, long, red needles, m. p. 154°, which readily loses methyl iodide when preserved, the *bromide*,

$$C_{14}H_{14}N_2S_2,2MeBr,$$

m. p. 154°, and the unstable *thiocyanate*, decomp. 102—105°.

o-Nitrophenyl methyl sulphide is reduced by sodium and methyl alcohol to *oo'-dimethylthiolazoxybenzene*, crystals, m. p. 72°, from which the corresponding *methosulphate*, $C_{14}H_{14}ON_2S_2,2Me_2SO_4$, yellow leaflets, m. p. (indefinite) 167—169° (decomp.) after becoming red at 160—162°, and the *methiodide*, $C_{14}H_{14}ON_2S_2,2MeI$, m. p. 103° (decomp.), are obtained.

oo'-Dimethylthiolazobenzene and the azoxy-compound combine with iodine in chloroform solution to give the *compounds*,

$$C_{14}H_{14}N_2S_2,2I_2,$$

m. p. 155° after evolving iodine at 140°, and $C_{14}H_{14}ON_2S_2,2I_2$, dark green needles, m. p. 113—114°; the corresponding sulphonium methosulphates when treated in aqueous solution with iodine and potassium iodide yield the *compounds* $C_{14}H_{14}N_2S_2,2MeI,2I_2$, m. p. 113—115° (decomp.), and $C_{14}H_{14}ON_2S_2,2MeI,2I_2$, m. p. 103° (decomp.) after darkening at 100°.

The following additive compounds are described: the *substance*, $C_{14}H_{14}N_2S_2,AgNO_3$, from the components in boiling aqueous-alcoholic solution, orange-coloured needles, which is completely decomposed into its components by hot water; the *salt*,

$$C_{14}H_{14}ON_2S_2,AgNO_3,$$

yellow needles; oo'-*diethylthiolazobenzene silver nitrate*,

$$C_{16}H_{18}N_2S_2,AgNO_3,$$

orange-coloured leaflets; *o-nitrophenyl methyl sulphide silver nitrate*, $NO_2\cdot C_6H_4\cdot SMe,AgNO_3$, yellow leaflets, m. p. 122°. H. W.

The Influence of Sulphonic Groups on the Colour of Azo-dyes. W. Meuly (*Helv. Chim. Acta*, 1923, **6**, 931—935).—To determine the influence of the number and position of sulphonic groups on the colour of azo-dyes, spectroscopic comparison was made of a large number of secondary bisazo-dyes, in which the first component was an aniline mono- or di-sulphonic or a naphthylamine mono-, di-, or tri-sulphonic acid, the middle component was cresidine (3-amino-*p*-cresol ether) and the end component an α- or β-naphthol mono-, di-, or tri-sulphonic acid. In every case, an additional sulphonic group, in either the first or the end component, deepens the colour, but the effect diminishes as the number of sulphonic groups increases. In the naphtholsulphonic acids, the effect of changing the position of the sulphonic group is smaller than the effect of an additional group. Similar results were obtained with a number of monoazo- and trisazo-dyes. As an example of the effect of additional sulphonic groups, the dye from sulphanilic acid, 3-amino-*p*-cresol ether and 1 : 4-naphtholsulphonic acid is red, whilst the corresponding dye using 1 : 3 : 6 : 8-naphtholtrisulphonic acid is violet. An absorption band may be shifted 10 to 20 μμ by a single sulphonic group, the influence being generally greater in the end component than in the first component. These results apply both to aqueous and to alcoholic solutions; in sulphuric acid and formic acid solutions the absorption bands are shifted in the opposite direction by sulphonic groups. [Cf. *B.*, 86.]

Certain Double Salts of Diazo-compounds with Lead Tetrachloride. E. Sakellarios (*Ber.*, 1923, **56**, [*B*], 2536—2541).—A series of double salts of the general formula $(ArN_2Cl)_2PbCl_4$ has been prepared. They are generally yellow in colour and insoluble in water. They are decomposed when heated with water with production of phenols. Thermal decomposition in the presence of inert solvents, such as carbon tetrachloride or benzene, gives *p*-chloronitrobenzene from the *p*-nitrodiazonium compound and mixtures of chlorinated benzenes from the benzenediazonium salt. The *p*-tolyl-, *m*-nitrophenyl-, and *p*-chlorophenyl-diazonium compounds are remarkably stable towards heat. The double salts dissolve in concentrated sulphuric acid with separation of lead tetrachloride and production of the diazonium sulphate. They couple immediately with an alkaline solution of β-naphthol and retain this power after being preserved during many months in a desiccator; an exception is, however, provided by the benzenediazonium salt which undergoes rapid decomposition. Direct sunlight and increased temperature facilitate the decomposition in a remarkable degree.

The lead tetrachloride solution is prepared by dissolving lead carbonate in concentrated hydrochloric acid and passing chlorine into the mixture at 10° until the suspended lead chloride is dissolved; excess of chlorine is removed in a current of air. The solution thus prepared is added to the requisite diazonium solution at −5° when the double salts separate. The following individual substances are described: the salt $(PhN_2Cl)_2PbCl_4$, straw-yellow leaflets, and the similarly constituted *compounds* from *p*-toluidine (a yellow, crystalline powder), *p*-chloroaniline (yellow leaflets), *p*-nitroaniline (yellow leaflets), and *m*-nitroaniline.

Ethylamine hydrochloride and lead tetrachloride give the *compound* $(EtNH_2\cdot HCl)_2PbCl_4$, yellow leaflets, which is decomposed by water with formation of ethyldichloroamine, b. p. 89°. H. W.

Characterisation of Aminoazo-derivatives. G. CHARRIER and A. BERETTA (*Gazzetta*, 1923, **53**, 729—760).—The authors find that the reaction suggested by Nietzki and Ernst (A., 1890, 1114) for characterising the primary aromatic amino-group (cf. Reitzenstein, A., 1903, i, 815; Meigen, A., 1908, i, 580; Küchel, *Diss. Giessen*, 1909) and based on the action of 1-chloro-2 : 4-dinitrobenzene in alcoholic solution and in presence of sodium acetate, followed by reduction of the resulting 2 : 4-dinitrodiarylamino-derivative to nitroaminodiarylamino-compound by means of sodium sulphide, is general for all aminoazo-derivatives irrespective of the position of the amino-group to the azo-group. The yield of the condensation product is moderately good from the *p*- and *m*-aminoazo-compounds, but less from the ortho-compounds, especially those of the naphthalene series. However, no resin is formed and the product is usually almost insoluble in alcohol, so that purification is easy.

[With A. NANI, L. ALBANI, A. DE LEONIBUS, G. DRISALDI, P. PAVESI, and O. TAVAZZANI.]—*2′-Benzeneazo-2 : 4-dinitrodiphenylamine*, $NPh{:}N\cdot C_6H_4\cdot NH\cdot C_6H_3(NO_2)_2$, obtained by the action of 1-chloro-2 : 4-dinitrobenzene on *o*-aminoazobenzene, forms slender, orange-yellow needles, m. p. 206°, dissolves in concentrated sulphuric acid with a green coloration, and resists boiling acetic anhydride. When suspended in alcohol and treated with sodium sulphide, it yields *2′-benzeneazo-4-nitro-2-aminodiphenylamine*,

$$NPh{:}N\cdot C_6H_4\cdot NH\cdot C_6H_3(NH_2)\cdot NO_2,$$

which crystallises in slender, deep red needles, m. p. 151°, and gives a *benzoyl* derivative, $C_{25}H_{19}O_3N_5$, crystallising in slender, yellow needles, m. p. 199°.

*2′-*p*-Tolueneazo-2 : 4-dinitro-4′-methyldiphenylamine*,

$$C_6H_4Me\cdot N{:}N\cdot C_6H_3Me\cdot NH\cdot C_6H_3(NO_2)_2,$$

prepared from *o*-tolueneazo-*p*-toluidine, forms lustrous, red needles, m. p. 232°, gives a green solution in concentrated sulphuric acid, and on reduction with sodium sulphide yields *2′-*p*-tolueneazo-4-nitro-2-amino-4′-methyldiphenylamine*,

$$C_6H_4Me\cdot N{:}N\cdot C_6H_3Me\cdot NH\cdot C_6H_3(NH_2)\cdot NO_2,$$

which crystallises in reddish-brown needles, m. p. 166°, and gives a *benzoyl* compound, $C_{27}H_{23}O_3N_5$, separating in yellow needles, m. p. 206°.

m-Aminoazobenzene may be obtained in satisfactory yield by benzoylating *m*-nitroaniline, reducing the *m*-nitrobenzanilide to *m*-aminobenzanilide, and converting the latter, by means of nitrosobenzene, into the benzoyl derivative of *m*-aminoazobenzene. The melting point of *m*-aminoazobenzene, given by Mills (T., 1895, 67, 917) as 56—57°, is found to be 62°.

3′-*Benzeneazo*-2 : 4-*dinitrodiphenylamine*,

$$NPh{:}N\cdot C_6H_4\cdot NH\cdot C_6H_3(NO_2)_2,$$

prepared from *m*-aminoazobenzene, crystallises in orange-yellow leaflets, m. p. 162°, and dissolves in concentrated sulphuric acid, giving a red coloration.

4′-Benzeneazo-2:4-dinitrodiphenylamine, prepared from *p*-aminoazobenzene, has m. p. 176° (cf. Walther and Lehmann, A., 1904, i, 352). 4′-*Benzeneazo*-4-*nitro*-2-*aminodiphenylamine*, $C_{18}H_{15}O_2N_5$, obtained by reducing the preceding compound, forms minute, deep red crystals, m. p. 164°; its *acetyl* compound crystallises in slender, yellow needles, m. p. 153°, and its *benzoyl* derivative in yellow needles, m. p. 226°.

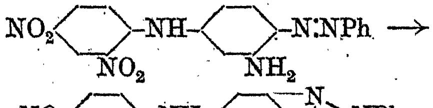
4′-o-*Tolueneazo*-2 : 4-*dinitro*-2′-*methyldiphenylamine*,

$$C_6H_4Me\cdot N{:}N\cdot C_6H_3Me\cdot NH\cdot C_6H_3(NO_2)_2,$$

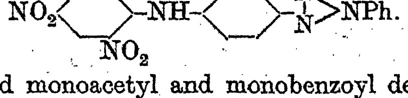
prepared from *o*-tolueneazo-*o*-toluidine, forms deep red needles, m. p. 186°, dissolves in concentrated sulphuric acid to a reddish-violet solution, and, on reduction with sodium sulphide and alcohol, yields 4′-o-*tolueneazo*-4-*nitro*-2-*amino*-2′-*methyldiphenylamine*, which separates in reddish-brown needles, m. p. 159°. 4′-p-*Tolueneazo*-2 : 4-*dinitro*-2′-*methyldiphenylamine*, prepared from *p*-tolueneazo-*o*-toluidine, crystallises in slender, lustrous, red needles, m. p. 151°, and dissolves in concentrated sulphuric acid, giving a violet-red coloration.

The action of 1-chloro-2 : 4-dinitrobenzene on *m*-diaminoazobenzenes results in the replacement by 2 : 4-dinitrophenyl of a hydrogen atom of the amino-group situate in the para-position to the azo-group. The amino-group in the ortho-position to the azo-group does not enter into the reaction, even when the chlorodinitrobenzene is taken in large excess; this appears to be due to the fact that the mono-condensation product is insoluble in alcohol and is hence removed from the sphere of reaction. The resulting diphenylamine derivatives have constitutions analogous to (I) and on oxidation yield the corresponding triazole compounds (II):

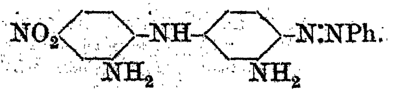
(I.)



(II.)



They readily yield monoacetyl and monobenzoyl derivatives, the substituent groups entering the amino-group in the ortho-position to the azo-group. By sodium sulphide in alcoholic solution they are reduced to benzeneazonitrodiaminodiarylamines of the general formula,



4′-*Benzeneazo*-2 : 4-*dinitro*-3′-*aminodiphenylamine*, $NPh:N \cdot C_6H_3(NH_2) \cdot NH \cdot C_6H_3(NO_2)_2$, obtained by the action of 1-chloro-2 : 4-dinitrobenzene on 4-benzeneazo-1 : 3-diaminobenzene (chrysoidine), crystallises in bright red needles, m. p. 187°, and gives a violet solution in concentrated sulphuric acid; its *acetyl* compound forms slender, orange-red needles, m. p. 218°, and its *benzoyl* compound, silky, red needles, m. p. 241°. *N*-Phenyl-2′ : 4′-*dinitrophenylamino*(3)*benztriazole* (formula II, above), crystallises in slender, yellow needles, m. p. 188°, and dissolves in concentrated sulphuric acid giving a reddish-yellow coloration.

4′-p-*Chlorobenzeneazo*-2 : 4-*dinitro*-3′-*aminodiphenylamine*, $C_6H_4Cl \cdot N:N \cdot C_6H_3(NH_2) \cdot NH \cdot C_6H_3(NO_2)_2$, prepared from 4-*p*-chlorobenzeneazo-1 : 3-diaminobenzene, forms lustrous, reddish-brown leaflets, m. p. 220°, and gives a blue solution in concentrated sulphuric acid.

4-p-*Chlorobenzeneazo*-1 : 3-*diaminobenzene* (p-*chlorochrysoidine*), $C_6H_4Cl \cdot N:N \cdot C_6H_3(NH_2)_2$, prepared by the interaction of *p*-chlorophenyldiazonium chloride on *m*-phenylenediamine hydrochloride, crystallises in lustrous, yellow needles, m. p. 140°, and its *hydrochloride* in slender, red needles, m. p. 225°. 4-p-*Bromobenzeneazo*-1 : 3-*diaminobenzene* (p-*bromochrysoidine*), $C_{12}H_{11}N_4Br$, similarly prepared, forms lustrous, golden-yellow needles, m. p. 155°, and its *hydrochloride* red needles, m. p. 213°. 4′-p-*Bromobenzeneazo*-2 : 4-*dinitro*-3′-*aminodiphenylamine*, $C_{18}H_{13}O_4N_6Br$, prepared from the preceding compound, forms lustrous, brick-red needles, m. p. 218°, and dissolves in concentrated sulphuric acid, giving a blue coloration.

4′-*Benzeneazo*-2 : 4-*dinitro*-3′-*amino*-6′-*methyldiphenylamine*, $NPh:N \cdot C_6H_2Me(NH_2) \cdot NH \cdot C_6H_3(NO_2)_2$, forms deep red needles, m. p. 273—274°, and dissolves to an emerald-green solution in concentrated sulphuric acid; its *acetyl* derivative forms orange-yellow needles, m. p. 196°, and its *benzoyl* derivative, orange-red needles, m. p. 252°. 4′-*Benzeneazo*-4-*nitro*-2 : 3′-*diamino*-6′-*methyldiphenylamine*, $C_{19}H_{18}O_2N_6$, formed on reduction of the preceding compound by means of sodium sulphide and alcohol, crystallises in lustrous, garnet-red prisms with metallic reflection, m. p. 244°.

4-p-*Chlorobenzeneazo*-1 : 3-*diamino*-6-*methylbenzene* (p-*chloromethylchrysoidine*), $C_6H_4Cl \cdot N:N \cdot C_6H_2Me(NH_2)_2$, prepared from *p*-chlorophenyldiazonium chloride and *m*-tolylenediamine hydrochloride, forms lustrous, golden-yellow leaflets, m. p. 169°, and its *hydrochloride*, lustrous, red needles, m. p. 235°. 4′-p-*Chlorobenzeneazo*-2 : 4-*dinitro*-3′-*amino*-6′-*methyldiphenylamine*, $C_{19}H_{15}O_4N_6Cl$, prepared from the preceding compound, crystallises in reddish-brown, lustrous needles, m. p. 286°, and dissolves in concentrated sulphuric acid, giving a green coloration; its *acetyl* compound forms slender, orange-yellow needles, m. p. 248°, and its *benzoyl* compound, orange needles, m. p. 285°. On reduction with sodium sulphide in alcoholic solution, it gives 4′-p-*chlorobenzeneazo*-4-*nitro*-

2 : 3′-*diamino-6′-methyldiphenylamine*, $C_{19}H_{17}O_2N_6Cl$, which forms slender, reddish-brown crystals, m. p. 262°. 4-p-*Bromobenzeneazo-1 : 3-diamino-6-methylbenzene* (p-*bromomethylchrysoidine*),

$$C_{13}H_{13}N_4Br,$$

crystallises in lustrous, golden-yellow leaflets, m. p. 177°, and its *hydrochloride* in lustrous, red needles, m. p. 236°. 4′-p-*Bromobenzeneazo-2 : 4-dinitro-3′-amino-6′-methyldiphenylamine*,

$$C_{19}H_{15}O_4N_6Br,$$

prepared from the preceding compound, crystallises in brownish-red leaflets, m. p. 290°, and yields a green solution in sulphuric acid; its *acetyl* derivative forms orange needles, m. p. 242°, and its *benzoyl* derivative, orange-yellow needles, m. p. 275°. 4′-p-*Bromobenzeneazo-4-nitro-2 : 3′-diamino-6′-methyldiphenylamine*,

$$C_{19}H_{17}O_2N_6Br,$$

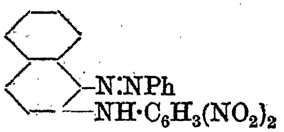
forms reddish-brown leaflets, m. p. 265°.

4-α-*Naphthaleneazo-1 : 3-diamino-6-methylbenzene*,

$$C_{10}H_7{\cdot}N{:}N{\cdot}C_6H_2Me(NH_2)_2,$$

prepared from α-naphthyldiazonium chloride on *m*-tolylenediamine hydrochloride, crystallises in brown needles with green, metallic reflection, m. p. 148°. 4′-α-*Naphthaleneazo-2 : 4-dinitro-3′-amino-6′-methyldiphenylamine*, $C_{10}H_7{\cdot}N{:}N{\cdot}C_6H_2Me(NH_2){\cdot}NH{\cdot}C_6H_3(NO_2)_2$, obtained from the preceding compound, forms reddish-brown needles with violet metallic reflection, m. p. 286°; its *acetyl* compound forms red needles, m. p. 268°, and its *benzoyl* compound, yellow needles, m. p. 246°. 4′-α-*Naphthaleneazo-4-nitro-2 : 3′-diamino-6′-methyldiphenylamine*, $C_{23}H_{20}O_2N_6$, forms reddish-brown needles, m. p. 214°. 4-β-*Naphthaleneazo-1 : 3-diamino-6-methylbenzene* (β-*naphthylmethylchrysoidine*), $C_{17}H_{16}N_4$, crystallises in yellow needles, m. p. 242°. 4-β-*Naphthaleneazo-2 : 4-dinitro-3′-amino-6′-methyldiphenylamine* forms a reddish-brown, crystalline powder, chars, without melting, above 300°, and gives a green solution in concentrated sulphuric acid; its *acetyl* compound separates in slender, yellow needles, m. p. 272°, and its *benzoyl* compound in orange needles, m. p. 267°. 4-β-*Naphthaleneazo-4-nitro-2 : 3′-diamino-6′-methyldiphenylamine*, $C_{23}H_{20}O_2N_6$, forms minute, reddish-brown crystals, m. p. 261°.

α-*Benzeneazo-β-naphthyl-2 : 4-dinitrophenylamine* (annexed formula), prepared by the action of 1-chloro-2 : 4-dinitrobenzene on α-benzeneazo-β-naphthylamine, crystallises in slender, red needles, m. p. 285°, and gives a greenish-blue solution in concentrated sulphuric acid. α-*Benzeneazo-β-naphthyl-4-nitro-2-aminophenylamine*, $NPh{:}N{\cdot}C_{10}H_6{\cdot}NH{\cdot}C_6H_3(NH_2){\cdot}NO_2$, forms reddish-brown needles, m. p. 147°.



α-o-*Tolueneazo-β-naphthyl-2 : 4-dinitrophenylamine*, $C_{23}H_{17}O_4N_5$, obtained from α-*o*-tolueneazo-β-naphthylamine, crystallises in slender, red needles, m. p. 223°, and dissolves in concentrated sulphuric acid to a greenish-blue solution. α-m-*Tolueneazo-β-naphthylamine* has m. p. 103—104°. α-m-*Tolueneazo-β-naphthyl-2 : 4-dinitrophenylamine* forms slender, red needles, m. p. 245°, and gives a greenish-blue solution in concentrated sulphuric acid. α-m-*Tolueneazo*-β-*naphthyl*-4-*nitro*-2-*aminophenylamine*, $C_{23}H_{19}O_2N_5$, is obtained as a dark red, microcrystalline powder, m. p. 116°. α-p-*Tolueneazo*-β-*naphthyl*-2 : 4-*dinitrodiphenylamine* crystallises in slender, red needles, m. p. 280°, and dissolves in concentrated sulphuric acid to a green solution. α-p-*Tolueneazo*-β-*naphthyl*-4-*nitro*-2-*aminophenylamine* forms microscopic, reddish-brown crystals, m. p. 155°.

α-p-*Chlorobenzeneazo*-β-*naphthyl*-2 : 4-*dinitrophenylamine*, $C_{22}H_{14}O_4N_5Cl$, crystallises in slender, bright red needles, m. p. 278°, and dissolves in concentrated sulphuric acid to a deep blue solution. α-p-*Bromobenzeneazo*-β-*naphthylamine*, $C_6H_4Br{\cdot}N{:}N{\cdot}C_{10}H_6{\cdot}NH_2$, forms red crystals, m. p. 135—136°. α-p-*Bromobenzeneazo*-β-*naphthyl*-2 : 4-*dinitrophenylamine* crystallises in slender, red needles, m. p. 263°, and gives a deep blue solution in concentrated sulphuric acid. 4-*Benzeneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine*, obtained from 4-benzeneazo-α-naphthylamine, forms long, bright-red, silky needles, m. p. 200°, and colours concentrated sulphuric acid bright blue. 4-*Benzeneazo*-α-*naphthyl*-4-*nitro*-2-*aminophenylamine* separates in minute, reddish-brown crystals, m. p. 181°, and its *acetyl* compound slender, red needles, m. p. 216°.

4-o-*Tolueneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine*, $C_6H_4Me{\cdot}N{:}N{\cdot}C_{10}H_6{\cdot}NH{\cdot}C_6H_3(NO_2)_2$, forms lustrous, reddish-brown crystals, m. p. 224°, and dissolves in concentrated sulphuric acid to a deep blue solution. 4-p-*Tolueneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine* crystallises in lustrous, bright red needles, m. p. 207°, and gives a blue solution in concentrated sulphuric acid. 4-p-*Tolueneazo*-α-*naphthyl*-4-*nitro*-2-*aminophenylamine* separates in reddish-brown crystals, m. p. 200°.

4-o-*Nitrobenzeneazo*-α-*naphthylamine*, $NO_2{\cdot}C_6H_4{\cdot}N{:}N{\cdot}C_{10}H_6{\cdot}NH_2$, crystallises in slender, metallic green needles, m. p. 165°. 4-o-*Nitrobenzeneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine*, $NO_2{\cdot}C_6H_4{\cdot}N{:}N{\cdot}C_{10}H_6{\cdot}NH{\cdot}C_6H_3(NO_2)_2$, forms a reddish-brown, microcrystalline powder, m. p. 212°, and yields a blue solution in concentrated sulphuric acid. 4-p-*Nitrobenzeneazo*-α-*naphthylamine* crystallises in deep red needles with metallic reflection, m. p. 252°. 4-p-*Nitrobenzeneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine* separates in slender, brownish-red needles, m. p. 263°, and dissolves in concentrated sulphuric acid giving a violet coloration.

4-p-*Chlorobenzeneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine*, $C_{22}H_{14}O_4N_5Cl$, forms slender, orange needles, m. p. 258°, and gives a green solution in concentrated sulphuric acid. 4-p-*Chlorobenzeneazo*-α-*naphthyl*-4-*nitro*-2-*aminophenylamine* separates in slender, deep red crystals, m. p. 228°.

4-α-*Naphthaleneazo*-α-*naphthyl*-2 : 4-*dinitrophenylamine*, $C_{10}H_7{\cdot}N{:}N{\cdot}C_{10}H_6{\cdot}NH{\cdot}C_6H_3(NO_2)_2$, crystallises in slender, brownish-red needles, m. p. 203°, and dissolves to a blue solution in concentrated sulphuric acid. 4-β-*Naphthaleneazo-α-naphthyl*-2 : 4-*dinitrophenylamine* forms reddish-brown needles, m. p. 241°, and dissolves in concentrated sulphuric acid giving a blue solution. T. H. P.

Reduction of Semicarbazones. E. J. Poth and J. R. Bailey (*J. Amer. Chem. Soc.*, 1923, **45**, 3001—3008; cf. A., 1922, i, 880).—Semicarbazones were reduced to the corresponding semicarbazides under a pressure of $1\frac{2}{3}$—$2\frac{1}{3}$ atm. of hydrogen in the presence of colloidal platinum. The minimum proportion of platinum necessary for efficient reaction varied considerably and when the reduction produced a basic substance the yield was increased by the addition of acid; the amount of acid required varied greatly. The following semicarbazides were prepared. *Fenchylsemicarbazide*, short needles, m. p. 181°. *Benzoylfenchylsemicarbazide*, a crystalline powder, decomp. 226°. *α-Phenylcarbamylfenchylsemicarbazide*, thin plates, m. p. 192°. *Carvomenthylsemicarbazide*, thin plates, m. p. 126° (decomp.), and its *hydrochloride*, short needles, decomp. 186°. *Benzoylcarvomenthylsemicarbazide*, m. p. 235°. *α-Phenylcarbamylcarvomenthylsemicarbazide*, clusters of radiating needles, m. p. 205°. cyclo*Hexylsemicarbazide*, needles, decomp. 185°, and its *hydrochloride*, m. p. 176—178°. *Benzoyl*cyclo*hexylsemicarbazide*, fine needles, m. p. 267° (decomp.). *α-Phenylcarbamyl*cyclo*hexylsemicarbazide*, microscopic short needles, decomp. 236°. Benzylsemicarbazide. *Benzoylmenthylsemicarbazide*, a crystalline powder, m. p. 216° (decomp.). *α-Phenylcarbamylmenthylsemicarbazide*, radiating needles, decomp. 184°. In the preparation of *iso*propyl, bornyl, and menthyl semicarbazides the proportion of colloidal platinum may be considerably reduced with advantage. The following triazoles were obtained by boiling the corresponding acyl semicarbazide with caustic alkali. 3-*Hydroxy*-5-*phenyl*-1-*fenchyltriazole*, thick, triangular plates, m. p. 234°. 3-*Hydroxy*-5-*phenyl*-1-*carvomenthyltriazole*, thin plates, m. p. 187°. 3-*Hydroxy*-1-cyclo*hexyl*-5-*phenyltriazole*, slender prisms, m. p. 232—234°. F. B.

Behaviour of Semicarbazides at Elevated Temperatures. E. J. Poth and J. R. Bailey (*J. Amer. Chem. Soc.*, 1923, **45**, 3008—3012; cf. preceding abstract).—cyclo*Hexylsemicarbazide*, when heated at 200° during twelve minutes yielded *di*cyclo*hexylcarbazide* (I), $CO(NH{\cdot}NH{\cdot}C_6H_{11})_2$, plates, m. p. 187°, and unchanged semicarbazide. When the semicarbazide was heated for one and a half hours at 180—185° the products were cyclo*hexylurazole* (II)  $\begin{matrix}NH{-}CO\\ CO{\cdot}NH\end{matrix}{>}N{\cdot}C_6H_{11}$, thin, prismatic plates, m. p. 271°, and *di*cyclo*hexylurazine* (III),  $C_6H_{11}{\cdot}N{<}\begin{matrix}NH{\cdot}CO\\ CO{\cdot}NH\end{matrix}{>}N{\cdot}C_6H_{11}$, needles or prisms, m. p. 197°; (I) was obtained in good yield when the semicarbazide was mixed with half its weight of urethane and heated at 160°, (II) was prepared by heating the semicarbazide and carbamide in molecular proportions, and (III) by decomposing the hydrochloride of the corresponding semicarbazide. F. B.

Arylazides. I. Conversion of *p*-Methylarylazides into Homologues of Quinol in Presence and Absence of Phenol. E. BAMBERGER and J. BRUN (*Helv. Chim. Acta*, 1923, 6, 935—941).—Some further experiments on the conversion of arylazides into homologues of quinol (cf. A., 1921, i, 716) are described. *p*-Tolylazide (5 g.) boiled with dilute sulphuric acid (1 : 3 by volume) gives about 1 g. of toluquinol, with some *p*-toluidine, a strong odour of cresol, but no aminocresol. From 25 g. of *m*-4-xylylazide, boiled for nine hours with dilute sulphuric acid, there were obtained 1·8 g. 1 : 3-dimethylquinol, 0·2 g. *as*-*m*-xylenol, 4·2 g. *as*-*m*-xylidine, and a considerable quantity of amorphous acids, bases, and resin. When *p*-tolylazide was boiled as before in dilute acid in presence of excess of phenol, from 6 g. of azide, 4·27 g. of *p*-hydroxyphenyl-*p*-tolylamine was obtained, and about 0·32 g. of toluquinol. The theory of the reactions involved has been previously discussed (*loc. cit.*).

E. H. R.

Arylazides. II. The Conversion of *p*-Methylarylazides into Imino-ψ-quinols and ψ-Quinols. E. BAMBERGER and J. BRUN (*Helv. Chim. Acta*, 1923, 6, 942—951).—Practical details are given of experiments previously reported (A., 1921, i, 716).

E. H. R.

Partial Decomposition of Proteins. E. ABDERHALDEN (*Z. physiol. Chem.*, 1923, **131**, 284—295).—A general description is given of the method of isolating the products of the partial hydrolysis of proteins. The protein is treated with 70% sulphuric acid at a low temperature, *e.g.*, at the ordinary temperature, or at blood heat, and the course of hydrolysis is followed by estimating the amino-nitrogen and comparing it with the total nitrogen, of which an estimation is made on the original protein. The sulphuric acid is removed as barium sulphate, and the filtrate is concentrated in a vacuum. If the product is a solid, it is extracted directly with ether in a Soxhlet apparatus; if it is a syrup, it is mixed with sand to a thick consistency and then extracted. It is afterwards extracted in turn with ethyl acetate, acetone, or methyl alcohol, and if necessary with other solvents such as chloroform or butyl alcohol. It is usually possible after evaporation of the solvent to obtain the fractions in a crystalline form, and they are purified according to their particular composition. In particular cases, variations at any stage may be advisable.

In an attempt to obtain the maximum yield of *d*-alanylglycine anhydride from silk clippings, the residue after hydrolysis, removal of sulphuric acid, and concentration, was treated with alcohol and hydrogen chloride, evaporated to dryness, and the residue dissolved in alcohol. The ammonium chloride separating at once on saturation with ammonia was filtered off. On keeping at 37°, a series of crystalline fractions was obtained, which were extracted in a Soxhlet apparatus with ethyl acetate. Eighty-five g. of pure glycylalanine anhydride was obtained from 1 kg. of silk clippings. Small quantities of glycyl-*l*-tyrosine anhydride and of *d*-alanyl anhydride (dimethylpiperazine) were also obtained.

One kg. of casein was hydrolysed with 10% sulphuric acid at 80°, and the product extracted with ethyl acetate, when 2·5 g. of crystals were obtained, decomp. 280°, and this compound proved to be *l*-leucyl-*d*-valine anhydride. On extracting the residue from the ethyl acetate extraction with acetone, crystals were obtained which on hydrolysis yielded leucine, valine, and glutamic acid, but there was no guarantee that the compound was pure. On further extraction with methyl alcohol, *d*-alanyl-*l*-leucine was obtained along with a crystalline *compound*, $C_{14}H_{23}O_3N_3$, m. p. 192°, $[\alpha]$ −183°, which yielded proline, *l*-leucine, and *d*-alanine on hydrolysis. It is apparently an anhydride formed from these acids by the elimination of 3 mols. of water. W. O. K.

The Formation of Carbon Dioxide during the Breakdown of Proteins in the Autoclave. V. S. Sadikov (*Biochem. Z.*, 1923, **143**, 492—495).—The method used for the catalytic hydrolysis of proteins by dilute hydrochloric acid under pressure (A., 1923, i, 867) leads in the case of gelatin to a slight formation of carbon dioxide amounting to 2% of the protein. It is suggested that this arises by decarboxylation of the amino-acids under the conditions used. Increasing pressure favours carbon dioxide formation. Nitrogen is also present in the residual gas in the autoclave and oxygen is largely absorbed during the process. J. P.

Hydrolysis in an Autoclave containing Nitrogen. V. S. Sadikov (*Biochem. Z.*, 1923, **143**, 496—503).—Arising from the author's work on the catalytic hydrolysis of proteins under pressure (cf. preceding abstract), it is found that a retention of nitrogen results when this is carried out in an atmosphere of the gas. Dextrose gives negative results, but a fixation is observed in the case of aspartic acid and to a less extent in the case of glycine. Similar treatment of fumaric and succinic acids in the autoclave leads to a notable retention of nitrogen, which is ascribed to the unsaturated compounds arising from these acids. J. P.

Separation of Proteins of White of Egg by the Acetone Method. M. Piettre (*Compt. rend.*, 1924, **178**, 91—93).—Details are given for the separation of the proteins of white of egg into a globulin, ovalbumin (coagulating at 52·5—53°, and having α_D −41·25°), and a glucoprotein. The latter (α_D −62·47°) reduces boiling Fehling's solution, and, at a moderate temperature, mercury and bismuth salts (in presence of alkali) and ammoniacal silver nitrate. E. E. T.

A Further Method of Determining the Isoelectric Point of Proteins and its Application to the Serum-albumins of Various Animals. L. Michaelis and T. Nakashima (*Biochem. Z.*, 1923, **143**, 484—491).—The optimum precipitation point of a mixture of mastic and gelatin in the presence of an acetate buffer approaches the isoelectric point of the latter as its relative amount is increased. This observation is made the basis of a method of determining the isoelectric points of various serum-albumins. To a series of tubes containing mastic sol and an acetate buffer at varying known p_H, increasing amounts of the albumin are added, and the p_H of the zone of optimum precipitation is observed to rise to a constant value beyond which addition of the albumin produces no further shift. This maximum p_H corresponds with the isoelectric point. The following values for the albumins examined were found: ox and guinea-pig, 4·65; dog, 4·66; puppy, 4·67; turtle and man, 4·68. J. P.

Nature of the Reaction between Carbophosphide and Blood-serum. G. Cuneo (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 294—298; cf. this vol., i, 100).—The interaction of carbophosphide and blood-serum yields a phospho-albumin which contains phosphorus in organic combination and either in the most highly oxidised state or as metaphosphoric acid. Since, further, nuclein bases occur among its products of hydrolysis, this phospho-albumin probably owes its existence to a hydrolytic process coupled with atmospheric oxidation, as a result of which the phosphorus of the carbophosphide enters the protein molecule as phosphoric oxide or as a hydrate of the latter. T. H. P.

Nature of the Reaction between Carbophosphide and Blood-serum. G. Cuneo (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 353—357; cf. this vol., i, 100, and preceding abstract).—The author has now investigated the behaviour of blood-serum towards a number of different compounds, some free from, and others containing phosphorus. Certain of these compounds do not denature the serum albumin molecule, which remains phosphorus-free, normally digestible by gastric juice, and without hindering effect on putrefactive processes. On the other hand, phosphorus di-iodide, ethylphosphine, and sodium hypochlorite effect denaturation of the protein molecule, the reaction, like that produced by carbophosphide, being probably of the nature of an auto-oxidation. The reaction of the serum-albumin with hypochlorite is complex, but the principal product is devoid of iron and phosphorus and exhibits the chemical and biological properties of the nucleic acids. T. H. P.

Formation of Methæmoglobin. II. W. Heubner and H. Rhode. **III.** R. Meier. **IV.** W. Heubner and R. Meier. **V.** W. Heubner, R. Meier, and H. Rhode (*Arch. expt. Path. Pharm.*, 1923, **100**, 117—127, 128—136, 137—148, 149—161).—I. A comparison of various substances which convert oxyhæmoglobin into methæmoglobin shows that the actions of potassium ferricyanide and of *p*-benzoquinone are almost identical in this respect.

Although the compound of hæmoglobin with nitric oxide is resistant to the action of reducing agents, it may be decomposed by means of indifferent gases and also by dialysis.

II. Optical and gasometric observations show that by the use of ferricyanide or of *p*-benzoquinone in varying proportions it is possible to produce a mixture of oxyhæmoglobin and methæmoglobin with the two constituents in any desired proportions. The last traces of oxyhæmoglobin are converted into methæmoglobin more easily by ferricyanide than by *p*-benzoquinone.

III. In the presence of hæmoglobin, quinol, *p*-aminophenol and hydrazobenzene are rapidly oxidised by atmospheric oxygen. Whereas the oxidation products of the first two of these substances are active in forming methæmoglobin, that of hydrazobenzene is not; the formation of methæmoglobin by hydrazobenzene therefore, must be due to an activation of the atmospheric oxygen in the process of oxidation of this substance.

Nitrosobenzene converts oxyhæmoglobin in part into methæmoglobin and in part into reduced hæmoglobin.

IV. Phenylhydroxylamine converts oxyhæmoglobin into methæmoglobin and is itself simultaneously converted into azoxybenzene; excess of phenylhydroxylamine in this reaction reduces the methæmoglobin first formed to hæmoglobin. Reduced hæmoglobin is unaltered optically by phenylhydroxylamine.

m-Nitrophenylhydroxylamine reacts similarly to phenylhydroxylamine but not so strongly. C. R. H.

The Natural Porphyrins. IV. Ooporphyrin. HANS FISCHER and F. KÖGL (*Z. physiol. Chem.*, 1923, **131**, 241—261).—Three hundred g. of gull's egg-shells were extracted with methyl alcohol containing hydrogen chloride, the extract was concentrated, made alkaline with sodium carbonate, and the precipitate washed and dried at 100°. The material was extracted with chloroform, which was then distilled off, and the residue dissolved in a little chloroform, precipitated by the addition of light petroleum, collected on a filter, and dried. It was then again dissolved in a little chloroform, and boiling methyl alcohol was added. *Ooporphyrin dimethyl* ester, $C_{34}H_{36}O_2N_4(OMe)_2$, was obtained as leaflets grouped in rosettes, m. p. 225—230°. The absorption bands of this compound are described at length. They resemble those of Kammerer's porphyrin. When ooporphyrin methyl ester from the shell of the gull or of the plover egg is treated with powdered iron in boiling acetic acid, crystals are obtained which although similar, are not identical, crystallographically and spectroscopically. The absorption bands of solutions of ooporphyrin from the egg-shells of various species of birds are described. W. O. K.

The Precipitation of the Lactoproteins by Copper Salts. A. J. J. VANDEVELDE (*Bull. Soc. chim. Belg.*, 1923, **32**, 376—386). —The lactoproteins have been precipitated by the addition of various salts of copper (sulphate, chloride, nitrate, and acetate) and the effect of washing the precipitates by water has been examined. With the sulphate, chloride, and nitrate, the results obtained are practically identical. Apart from the case of the acetate precipitate, washing by water appears to have no influence on the composition of the precipitate and its copper content. A second series of experiments was carried out to determine the composition of the solid and liquid phases forming the primitive complex, The results obtained show that the quantity of copper in the precipitates increases as the initial concentration of the copper increases, whilst the ratio of the quantity of copper precipitated to the total quantity of copper employed diminishes, generally in proportion as the initial concentration of the copper increases. The anion present is shown to have a visibly marked effect on the precipitation of the metallic kation. Galeotti's conclusions (A., 1904, i, 355) as to the equilibrium between the proteins and sulphate of copper are not upheld. F. G. P.

Triphosphonucleic Acid and Thymic Acid. S. J. THANNHAUSER (*Z. physiol. Chem.*, 1923, **131**, 296—303; cf. Feulgen and Rosenbeck, A., 1923, i, 618, and Feulgen, *ibid.*, i, 964; also Thannhauser and Sachs, A., 1920, i, 201).—The author has found that after hydrolysing triphosphonucleic acid by alkali, the adenosine may be precipitated as picrate and has obtained almost the theoretical yield of this picrate. He does not admit the validity of the criticism of Feulgen (*loc. cit.*), who doubts the existence of the acid, but he considers that triphosphonucleic acid is with great probability a pure substance. The author also criticises the results of Feulgen (cf. *loc. cit.*) regarding thymic acid. W. O. K.

Influence of Time on the Physico-chemical Properties of Gelatin Solutions. R. DE IZAGUIRRE (*Kolloid Z.*, 1923, **33**, 337—347).—The effect of time on the viscosity, multi-rotation, and the action of electrolytes on gelatin solutions has been examined. It is shown that in the presence of hydrochloric acid the influence of time on the viscosity of gelatin solutions passes through a minimum with increasing concentration of hydrochloric acid. This minimum corresponds with the initial viscosity of the solution. The same regularity is found with the time change of the osmotic pressure, whereby the change with time is smaller the larger the osmotic pressure. Since the maximum of the viscosity and the osmotic pressure is closely connected with the swelling, it follows that the time change takes place in the opposite sense to the swelling, that is, the greater the degree of swelling the smaller the time change. Since the viscosity serves as a measure of the gelatinisation this must be regarded as an "unmixing" process and not as the formation of a hypothetical new modification of the gelatin. The optical rotation of gelatin solutions increases with time in such a way that a curve plotted between the logarithm of the angle of rotation and the logarithm of the time is a straight line. The multirotation is expressed by the formula $[\alpha]_D = K.t^n$, in which for a 1% solution of gelatin $K=209$ and $n=0{\cdot}082$. J. F. S.

The Isoelectric Point of Gelatin from Hide and Bone. O. GERNGROSS and S. BACH (*Biochem. Z.*, 1923, **143**, 542—552).—The isoelectric points of various preparations of gelatin have been found to range from p_H 4·45 to 5·55 according to their source. [Cf. also *B.* Feb.] J. P.

The Displacement of the Isoelectric Point of Gelatin by Formaldehyde. O. GERNGROSS and S. BACH (*Biochem. Z.*, 1923, **143**, 533—542).—The isoelectric points of two preparations of gelatin were lowered from p_H 5·05 to 4·6 and from p_H 4·75 to 4·3, respectively, by the presence of formaldehyde. J. P.

Points of Minimum Swelling of Ash-free Gelatin. J. A. Wilson and E. J. Kern (*J. Amer. Chem. Soc.*, 1923, **45**, 3139—3140; cf. A., 1923, i, 68).—The two points of minimum in the curve showing the degree of swelling of gelatin as a function of the p_H value, namely at 4·7 and 7·7, were confirmed when using ash free gelatin. The points coincide with those at which minimum values for the wave-length of maximum absorption in the ultra-violet are observed. F. B.

Diffusion of Arsenic [Trioxide] in Gelatin. R. Schaefer (*Kolloid Z.*, 1923, **33**, 286—289).—A clear, transparent gel containing arsenious oxide and suitable for dental purposes, may be prepared by adding a few c.c. of hot 30% gelatin solution to a hot solution of arsenious oxide with vigorous stirring. The solution is evaporated slowly on a water-bath and every fifteen minutes a quarter of the evaporated water is replaced by gelatin solution. This process is continued until the concentration desired is reached and the whole allowed to cool to a clear gel. In this way, a gel containing 12—15% of arsenious oxide and 20—30% of gelatin is obtained. The diffusion of arsenious oxide in gelatin has been investigated by laying small portions of the above described gel, and a paste of the powdered oxide and water on a large piece of gelatin and, after sufficient time has elapsed, examining the gelatin by exposing it to hydrogen sulphide. In the case of the arsenic gel, it is found that the amount of arsenic diffused falls off quite regularly as the distance travelled increases, but with the paste there is no apparent diffusion beyond the surface of the gelatin, although this has undoubtedly taken place. The author is of the opinion that in the paste simple molecules are present, but in the gel more complicated molecules are present and these move more slowly, but the total amount of arsenic diffused is greater in the latter case than in the former. J. F. S.

Reaction of Alkaloids with Gelatin [Solutions] containing Iodine. H. Handovsky and E. du Bois-Reymond (*Kolloid Z.*, 1923, **33**, 347—348).—Liesegang rings are produced when a solution of 1 : 1000 pilocarpine hydrochloride is placed on a gel containing 3% of gelatin, 0·6% of potassium iodide, and 0·4% of iodine. The rings are alternately reddish-yellow and dark brown, and are about 1—2 mm. apart. Similar, but differently coloured, rings are produced with strychnine nitrate 1 : 1000 and papaverine hydrochloride 1 : 100. J. F. S.

The Composition of Spinning Silk. E. Abderhalden (*Z. physiol. Chem.*, 1923, **131**, 281—283).—From the product of the hydrolysis of spinning silk by 70% sulphuric acid at 37° there has been isolated glycyl-*l*-tyrosine anhydride, m. p. 282°, and glycyl-*d*-alanine anhydride, m. p. 245°. W. O. K.

The Influence of Temperature on the Action of Amylase. The Action on the Saccharifying Power of Amylase. T. CHRZĄSZCZ (*Biochem. Z.*, 1923, **142**, 417—439).—The influence of temperature on the activity of the amylases of various cereals at the optimum p_H of 4·9 is not uniform. The optimum ranges found are: for barley amylase 49—54°, for rye and wheat amylases 49—55°, for oats amylase 51—53°, and for buckwheat amylase 50—55°. In the cases of maize (56—57°) millet (58—59°), and African millet (62—64°) the optima quoted in brackets lie above the temperatures at which destruction of the enzyme begins. In aqueous solutions, barley amylase is inactivated at 61—62°, rye and wheat amylases at 63—64°, and the other varieties at 65—66°. In general, plant amylases are completely destroyed in one hour when exposed to a temperature of 75°. Amylases from the same genera but of different varieties show the same susceptibility to alteration of temperature at the optimum p_H. Aqueous malt extracts prepared by shaking for at least one hour give a precipitate when heated at 50°, but if the shaking be of shorter duration (thirty minutes), precipitation does not commence below 55—60°. The precipitate does not affect the activity of the enzyme. Rye-malt extract is exceptional in giving at most a slight opalescence even at 80°. J. P.

Potato Amylase. H. HAEHN and H. SCHWEIGART (*Biochem. Z.*, 1923, **143**, 516—526).—Potato amylase is activated by sodium chloride and fluoride, and by potassium, calcium, barium, and magnesium chlorides. It is inhibited by the salts of the heavy metals. Amino-acids have an activating effect (cf. Doby, *Biochem. Z.*, 1914, **67**, 166). Potato amylase after being freed from most of its salts by dialysis or ultra-filtration loses much, but not all, of its activity, but is reactivated by the addition of the salts of the alkali or alkaline-earth metals. A method of combined dialysis and ultra-filtration yields inactive, salt-free preparations of the amylase, which are reactivated by salts. It is concluded that potato amylase consists of an inactive organic constituent together with an indispensable activating mineral salt. J. P.

The Hexose Monophosphatase of Takadiastase. J. NOGUCHI (*Biochem. Z.*, 1923, **143**, 190—194).—A phosphatase is present in takadiastase which hydrolyses barium and sodium hexose monophosphates at 37°. In the former case, barium phosphate separates as a gel, and in the latter the extent of the hydrolysis, which may be practically quantitative, is dependent on the concentration of the enzyme. J. P.

The Cellase of Takadiastase. C. NEUBERG and O. ROSENTHAL (*Biochem. Z.*, 1923, **143**, 399—401).—Takadiastase contains a cellase which at 37° completely hydrolyses cellobiose to dextrose in five days. J. P.

Hemicellusose. IV. Cellobiase and Lichenase. H. PRINGSHEIM and J. LEIBOWITZ (*Z. physiol. Chem.*, 1923, **131**, 262—268).—Lichenin, which is hydrolysed to dextrose by malt extract, has been acetylated and then hydrolysed to octoacetylcellobiose (Karrer and Joos, A., 1923, i, 541). It ought therefore to be possible to show that malt extract hydrolyses it first to cellobiose by means of a lichenase, and then to glucose by cellobiase, *i.e.*, to show that both lichenase and cellobiase are present in malt extract. This is verified as cellobiose is hydrolysed to dextrose by malt extract at 37°, and p_H 5, and on the other hand, malt extract, after being kept for three months, hydrolyses lichenin only to cellobiose, as the cellobiase apparently disappears on keeping. The presence of cellobiose was determined by the determination of the reducing power and of the rotation of the solution, and also by the formation of the osazone. W. O. K.

Synthetic Action of α-*d*-Mannosidase in Presence of some Monohydric Alcohols. H. Hérissey and J. Cheymol (*Compt. rend.*, 1924, **178**, 123—125).—α-*d*-Mannosidase effects a partial conversion of mannose, in presence of ethyl, propyl, *iso*propyl, and *n*-butyl alcohols, into the corresponding *d*-mannosides (cf. A., 1923, i, 497). E. E. T.

The Separation of the Anti-neuritic Vitamin by Means of its Picrate. G. Bertrand and A. Seidell (*Bull. Soc. Chim. biol.*, 1923, **5**, 794—796).—The crude extract containing the active material is separated from inorganic substances as far as possible, dissolved in 60% alcohol and treated with a solution of picric acid in methyl alcohol. The crude picrate thus obtained is active in amounts of 2 mg. per diem when added to a diet of polished rice and administered to pigeons. On recrystallisation of the picrate from water two separate substances are obtained; one crystallises in needles, m. p. 202°, and is inactive; the other forms a crystalline powder, m. p. 160°, and is active. C. R. H.

Additive Products of the Phosphineimines. M. Masriera (*Anal. Fís. Quím.*, 1923, **21**, 418—435; cf. Staudinger and Hauser, A., 1922, i, 68).—The constitution of the additive products formed from phosphineimines and alkyl or acyl chlorides is discussed. Triphenylphosphinephenylimine reacts with acetyl chloride in ethereal solution, giving a white *compound* to which the formula $PPh_3\!:\!NPhAcCl$ is assigned. It is unstable and gives on decomposition acetanilide and triphenylphosphine oxide. The additive *compound* of triphenylphosphinephenylimine with methyl iodide is a white substance having m. p. 235°. Attempts to obtain addition of a second molecule of methyl iodide were unsuccessful. The additive *compound* of toluene-*p*-sulphonyl chloride with triphenylphosphineimine is a white, crystalline substance which decomposes when heated, forming resins. On keeping a mixture of triphenylphosphinephenylimine and toluene-*p*-sulphonyl chloride in ethyl-alcoholic solution for three months, two substances are obtained, namely, *triphenylphosphine*-p-*toluenesulphonylphenylammonium hydroxide*, $PPh_3\!:\!NPh(SO_2\cdot C_6H_4Me)\cdot OH$, a white crystalline substance, m. p. 191°, and its *isomeride*, for which the formula

$$OH\cdot PPh_3\cdot NPh\cdot SO_2\cdot C_6H_4Me$$

is suggested; it is crystalline and has m. p. 115°. G. W. R.

The Syntheses of Arsenic Acids by Means of Diazonium Salts. Z. Földi (*Ber.*, 1923, **56**, [*B*], 2489—2498).—Evidence is adduced in favour of the view that the diazonium arsenite is the primary product of Bart's arsinic acid synthesis (cf. Schmidt, A., 1920, i, 897). The transformation of the arsenious ion into the arsinic group is simply explained in accordance with Werner's theory if the constitution $H\left[\begin{matrix}OH\\ HO\cdot AsOH\\ OH\end{matrix}\right]$ or $H\left[OAs\begin{matrix}OH\\ OH\end{matrix}\right]$ is assigned to arsenious acid, and it is regarded as functioning as a monobasic acid, as is generally the case towards alkali kations including the diazonium-ion. In arsenious acid, the arsinic group exists therefore preformed. The production of the arsinate can therefore be explained by assuming that the diazonium kation present in the second sphere of the central arsenic atom enters the first sphere thereby transforming the tervalent into quinquevalent arsenic atom and that the diazoarsinic acid decomposes with evolution of nitrogen.

p-Toluidine is diazotised in hydrochloric acid solution by means of sodium nitrite; the cooled solution is saturated with hydrogen chloride, filtered to remove the precipitated sodium chloride, and treated with arsenic chloride, whereby a paste of colourless, granular crystals is produced without evolution of nitrogen. The product can be coupled with phenols or amines, thus showing the diazonium group to be intact. The addition of alkali hydroxide to the aqueous solution causes immediate evolution of nitrogen and the development of the colours and odours characteristic of Bart's reaction. In the presence of sodium hydrogen carbonate, the arsenious acid can be titrated with iodine, the end-point being shown by the formation of a dark coloured diazonium periodide. According to experimental conditions, the *compounds* $C_6H_4Me\cdot N_2Cl,AsCl_3$, $C_6H_4Me\cdot N_2Cl,2AsCl_3$, $C_6H_4Me\cdot N_2Cl,AsCl_2\cdot OH$, and $C_6H_4Me\cdot N_2Cl,AsCl_3,AsCl_2\cdot OH$ can be obtained. The first two of these are extremely labile and particularly sensitive to moisture; they can only be obtained from solutions which are completely saturated with hydrogen chloride. The fourth substance has m. p. 94—98° (decomp.); it readily loses hydrogen chloride and passes into the *pentachloro*-salt, $C_6H_4Me\cdot N_2(As_2Cl_5O)$, pale pink octahedra, m. p. 111—112° (decomp.), whereas when its solution in absolute alcohol is treated with anhydrous ether it gives the compound $C_6H_4Me\cdot N_2Cl,AsCl_2\cdot OH$, colourless crystals, m. p. about 90° (decomp.). The *salt*, $C_6H_4Me\cdot N_2(AsBr_3\cdot OH)$, m. p. 105°, is described. The hydroxy-chloro-salts can also be prepared from solid *p*-toluenediazonium chloride and arsenic trichloride in concentrated, absolute alcoholic solution.

The diazonium chloroarsenites decompose vigorously in aqueous or alcoholic solution, or in suspension in organic media with evolution of nitrogen in the presence of Gattermann's copper powder or cuprous chloride. In alcoholic solution, the reaction is very complex, giving di-*p*-tolyl, *p*-tolyl ethyl ether, arsenic acid, *p*-tolylarsinic acid, ethyl *p*-tolylarsinate, and *p*-tolylchloroarsine.

A study of the action of *p*-toluenediazonium sulphate on barium arsenite in the presence of water shows that diazonium arsenites are capable of existence in aqueous solution in the presence of an excess of arsenious acid, but attempts to obtain them in the solid state were not successful. Attempts to prepare solutions of diazonium arsenites in the absence of excess of arsenious acid are rendered difficult by the impossibility of preparing undecomposed diazonium hydroxide solutions. When, however, solutions of *p*-toluenediazonium sulphate, barium hydroxide, and arsenious acid in the molecular proportion 1 : 1 : 1 are mixed a pale yellow, turbid alkaline solution is obtained which is alkaline towards litmus but gradually becomes acidic; decomposition of the diazonium arsenite is shown to occur in accordance with the two schemes:

$$2C_6H_4Me{\cdot}N_2{\cdot}O{\cdot}As(OH)_2 = C_6H_4Me{\cdot}AsO(OH){\cdot}O{\cdot}N_2{\cdot}C_6H_4Me + N_2 + As(OH)_3$$ and

$$2C_6H_4Me{\cdot}N_2{\cdot}O{\cdot}As(OH)_2 = C_6H_4Me{\cdot}N_2{\cdot}AsO(OH){\cdot}O{\cdot}N_2{\cdot}C_6H_4Me + As(OH)_3,$$

the second being the more important. H. W.

Physiological Chemistry.

The Influence of Various Carbohydrates and Amino-acids on the Blood and Urinary Sugar of the Healthy Organism. A. SCHÄTTI (*Biochem. Z.*, 1923, **143**, 201—220).—In general, the ingestion by normal individuals of 20 g. of the following carbohydrates produces a hyperglycæmia the intensity of which diminishes in the order given: dextrose, lævulose, sucrose, lactose, galactose. The same amounts of starch, glycine, and alanine produce no hyperglycæmia, but after the ingestion of 100 g. of starch the rise in blood-sugar is as great as, but more delayed than, that produced by 100 g. of dextrose. Peptone and coffee give no hyperglycæmia. Lævulose is excreted more quickly and in greater amount than dextrose, and the sugar excreted after ingestion of sucrose consists chiefly of lævulose. Galactose seems to be excreted largely unchanged by the kidneys. Glycosuria following ingestion of dextrose increases with increasing hyperglycæmia, but the former shows a more delayed maximum than the latter. Glycosuria is not dependent on diuresis, but is regarded as a secretory process. J. P.

Blood-clotting as an Agglutination Process. E. HEKMA (*Biochem. Z.*, 1923, **143**, 105—110).—A theoretical paper in which the view is advanced, as a result of the author's previous work, that fibrin formation is a crystallisation process involving the dehydration and agglutination of fibrinogen amicrons. Thrombin is regarded, not as a fibrin ferment, but as an agglutinin, and fibrin consists of fibrinogen plus agglutinin. J. P.

The Influence of Chemicals on Erythrocyte Membranes by Changes in Corpuscular Volume. B. S. NEUHAUSEN and J. E. BRESLIN (*Bull. Johns Hopkins Hosp.*, 1923, **34**, 199—201).—A study of the effects of the salts of the blood and of dextrose on the erythrocyte membranes as shown by a comparison of cell volumes in iso-osmotic solutions. Ions cause swelling in the order, $Ca < Na < K$. The contracting action of calcium, as opposed to the swelling action of potassium, is specially pointed out. In the case of blood-corpuscles, the membranes are very complex colloidal mixtures, the swelling or precipitation of any component of which will loosen the whole structure.

CHEMICAL ABSTRACTS.

The Rôle of Pancreatic Juice in the Digestion of Proteins. Relative Importance of Trypsin and Erepsin. E. F. TERROINE and ST. J. PRZYLECKI (*Arch. internat. physiol.*, 1923, **20**, 377—396; *Ber. ges. Physiol.*, 1923, **20**, 64; from *Chem. Zentr.*, 1923, iii, 1290).—Pancreatic juice not activated by kinase attacks the normal products of gastric digestion. With activation by kinase, the action is increased. The relative importance of erepsin and trypsin depends on the degree of previous gastric digestion; where this is small, trypsin plays the more important part, but is less important where gastric digestion is more complete. As pancreatic digestion proceeds, the effect of trypsin recedes relative to that of erepsin.

G. W. R.

Effect of Magnesium Sulphate and Metallic Magnesium on Metabolic Exchanges. R. REDING and A. SLOSSE (*Compt. rend. Soc. biol.*, 1923, **88**, 644—646; from *Chem. Zentr.*, 1923, iii, 1108). —Intramuscular injection of 70 c.c. of 10% magnesium sulphate solution decreases the output of total nitrogen, uric acid, and sodium chloride, whilst the output of magnesium is increased. In a rectal carcinoma, injection of 20 c.c. of 10% magnesium sulphate solution was followed by decreased output of total nitrogen, amino-nitrogen, and sodium chloride, and increased output of uric acid and creatine. Similar effects were observed in a rabbit after introduction under the skin of a piece of metallic magnesium.

G. W. R.

The Internal Secretion of the Genital Organs. I. The Genital Organs and Carbohydrate Metabolism. S. TSUBURA (*Biochem. Z.*, 1923, **143**, 248—290).—Castration has no effect on the blood-sugar of fasting dogs, but in the sexually mature animal the operation produces a lowered sugar tolerance. The same effect is produced by ligature of one spermatic cord and extirpation of the opposite testicle, by ligature of both cords, or by exposing the genital glands to *X*-rays. These operations produce a degeneration of the sperm-cells, but do not affect the interstitial cells. The lowered sugar tolerance may be temporarily raised by transplantation of the sexual organs of another animal, but not by feeding the organs or by injection of extracts. Glycogen formation, glycogenolysis, and glycolysis of the blood-sugar in vitro are somewhat delayed after castration, but the blood amylase is unchanged.

After castration, the reactions of the blood-sugar to adrenaline, diuretin, and pituitrin are increased, but thyroid feeding has no effect, although it raises the low sugar tolerance of the castrated animals. The kidneys of the latter are more permeable to sugar, but the excretion of phenolsulphonephthalein is delayed as compared with the normal condition. In general, parallel experiments on male and female dogs gave similar results. The other endocrine organs show alterations after castration, and the observed results may not be wholly due to disturbances of the internal secretory functions of the genital organs. J. P.

The Internal Secretion of the Genital Organs. II. The Genital Organs and Respiratory Gaseous Metabolism. S. Tsubura (*Biochem. Z.*, 1923, **143**, 291—322).—Castration produces a lowered gaseous metabolism which becomes apparent about one month after the operation. A similar effect is produced by ligature of one spermatic cord and removal of the opposite testicle. Transplantation of the testes of another animal raises the gaseous exchange whilst feeding experiments are ineffective. Dogs in heat show no increased gaseous metabolism. Thyroid feeding raises the low gaseous exchange of castrated animals. The combined results of thyroid feeding on the sugar tolerance (cf. preceding abstract) and gaseous metabolism of castrated dogs are explained as being due to a moderate stimulation of the sluggish carbohydrate metabolism by the thyroid hormone. J. P.

The Ferments in the Placenta. K. Maeda (*Biochem. Z.*, 1923, **143**, 347—364).—Extracts of the placenta contain diastase in considerable amount, in part derived from the parental blood. Carboxylase and small quantities of lactase and invertase are present, but glycolytic enzymes are not found. Of proteolytic enzymes, erepsin, a weak trypsin, and traces of pepsin, but no rennin, are found. An asparagine deaminase is present. Mono- and tributyrases are found, and the latter, being stable to both quinine and atoxyl, is thus differentiated from serum lipase. Histozyme, a feeble salicylase, and an oxydase acting on pyrocatechol, adrenaline, and dihydroxyphenylalanine, but not on tyrosine, are present.

J. P.

The Site of Origin of Bilirubin. A. R. Rich (*Bull. Johns Hopkins Hosp.*, 1923, **34**, 321—329).—Hæmoglobin introduced into the blood-stream of a dog without a liver, and circulating actively for as long as five and a half hours is not transformed into bilirubin. Since, however, the production of bilirubin from circulating hæmoglobin takes place rapidly and readily in a dog with a liver through which the blood-stream passes, it is concluded that the liver is necessary for the transformation of circulating hæmoglobin into bilirubin. The conclusions are applicable only to hæmoglobin circulating in the blood-stream, not to hæmoglobin liberated into the tissues from extravasated blood; the conversion of hæmorrhage hæmoglobin into bilirubuin (hæmatoidin) is a purely local phenomenon, the exact mechanism of which is unknown.

Chemical Abstracts.

[Fish] Liver Oils. M. Tsujimoto (*J. Chem. Ind. Japan*, 1923, **26**, 482—486).—The oil from the Jewfish (*Stereolepis ischinagi* (Hilg.), contains a large amount of peculiar unsaponifiable matter (up to 50%), which is a viscous substance of reddish-orange colour, having a resinous odour, and showing much resemblance to colophony when dried at 100° for several hours. The name "liver-resin" is proposed for it. Liver oil from *Erilepis zonifer* (Lock.) also contains a similar substance (about 4%). These oils and the unsaponifiable matter (especially in carbon disulphide solution) give a deep violet coloration with sulphuric acid. With a sample of *S. ischinagi* liver oil, the coloration was observed to be about one hundred times as strong as that of a cod-liver oil. K. K.

The Highly Unsaturated Acids in Cod-liver Oil. M. Tsujimoto and K. Kimura (*J. Chem. Ind. Japan*, 1923, **26**, 1162).—By the potassium salt–ether method, and the lithium salt–acetone method, a mixture of highly unsaturated acids was obtained. By converting it into the methyl ester, a fraction (about 4% of the oil) boiling at 220—226°/5 mm. was isolated. The analysis of the ester and the fatty acid from the ester gave $C_{22}H_{33}O_2Me$ and $C_{22}H_{34}O_2$ respectively, and behenic acid was produced from the latter by hydrogenation. Cod-liver oil therefore contains a large amount of clupanodonic acid, $C_{22}H_{34}O_2$. The part of the methyl ester boiling below 220°/5 mm. is supposed to contain a large amount of a highly unsaturated acid containing eighteen or twenty carbon atoms. K. K.

Further Studies on Autoxidations and Oxido-reduction Processes. V. E. Abderhalden and E. Wertheimer (*Pflüger's Archiv*, 1923, **200**, 176—193; from *Chem. Zentr.*, 1923, iii, 1290).—The reducing power of muscle in which thermal rigor has been induced is three or four times that of normal muscle. In chemical rigor and rigor mortis, there is a similar increase in reducing power. An increase also occurs during normal or tetanic contraction. It is supposed that such increases are associated with the presence of a thiol group in the muscle fibres. Cysteine serves as a hydrogen carrier and acceptor. A scheme for a stable oxido-reduction system is given. G. W. R.

A Methylation Function of the Thyroids and the Biological Significance of Iodine. B. Stuber, A. Russman, and E. A. Proebsting (*Biochem. Z.*, 1923, **143**, 221—234).—If guanidineacetic acid be administered intravenously to young dogs, an increase of blood creatine–creatinine follows. No such increase occurs in thyroidectomised animals, but if these be given dried thyroid or potassium iodide per os, before the injection of guanidineacetic acid, they react like the normal animals. The blood of normal dogs, but not of thyroidectomised dogs, is also effective in this respect. It is concluded that the capacity of the organism to methylate guanidineacetic acid, and so form creatine and creatinine, is dependent on the integrity of the thyroids, and that iodine compounds are necessary for this methylation process. J. P.

The Oxytocic–Pressor–Diuretic Principle of the Infundibular Portion of the Pituitary Gland. J. J. Abel, C. A. Rouiller, and E. M. K. Geiling (*J. Pharm. exp. Ther.*, 1923, **22**, 289—316).—After a purification of the gland material by precipitation with mercuric chloride, phosphotungstic acid, and tannic acid in succession, the residue is dissolved in an alcoholic solution of tartaric acid and re-precipitated with ether. The resulting precipitate is called the tartrate of the active principle. Its action on the isolated uterus of the guinea-pig may be as much as 1,250 times as great as that of histamine phosphate, whilst it also retains the diuretic and pressor action characteristic of the pituitary extract. C. R. H.

Anaërobic Processes Involved in Muscular Activity. W. Hartree and A. V. Hill (*J. Physiol.*, 1923, **58**, 127—137).—In muscle, 0·1% of lactic acid can be produced so rapidly by exercise or by stimulation that no appreciable escape of carbon dioxide or of acid is possible. Hence if the hydrogen-ion concentration inside a muscle is not to rise to an excessive degree during exercise, there must be some buffer in it, much more effective than a bicarbonate solution. Meyerhof (*Pflüger's Archiv*, 1922, **195**, 22) has emphasised that in a frog's muscle the absolute amount of bicarbonate present, as determined from the carbon dioxide driven out from the muscle by excess of acid, is quite inadequate to neutralise the lactic acid liberated in severe stimulation. Even if all the carbon dioxide were driven out, only one-seventh to one-tenth of the lactic acid could be neutralised.

The authors further calculate that the 0·3% inorganic phosphate in muscle (a mixture of KH_2PO_4 and K_2HPO_4) is also quite inadequate to keep the P_H within the extreme limits observed, viz., a change from 7·5 to 6·9). Bicarbonate and phosphate together are insufficient to neutralise half the lactic acid formed. There must be, as Meyerhof assumes, some other powerful buffer, doubtless an alkali–protein salt. The addition of lactic acid to shed blood also produces only a fraction of the change in the hydrogen-ion, which would result in a bicarbonate solution of the same concentration; here also alkali protein must play a considerable part.

The authors confirm the existence of a secondary maximum in the production of heat in a muscle in the absence of oxygen; this maximum occurs after about two and a half minutes (see the following abstract for its interpretation). A "balance sheet" is given of the heat evolved in the different phases of muscular contraction; it shows that during the recovery process something between 1/4·7 and 1/6 of the lactic acid removed is oxidised, the rest being reconverted into glycogen. G. B.

Heat of Combustion of Glycogen in Relation to Muscular Contraction. W. K. Slater (*J. Physiol.*, 1923, **53**, 163—167).—Glycogen (from *Mytilus edulis*, a convenient source) only becomes anhydrous at 100° in a vacuum over phosphoric oxide (cf. Harden and Young, T., 1902, **81**, 1224). Dried by the method of Atkins and Wilson (T., 1915, **107**, 916), it has the composition $(C_6H_{10}O_5,H_2O)_n$.

The heat of combustion seems previously to have been determined with slightly hydrated material. The author finds the heat of combustion of hydrated glycogen to be 3,883 cal. per gram, which is about 100 cal. higher than that calculated from Stohmann and Schmidt's value, 4,190 (A., 1895, ii, 102), for (presumably imperfectly) dehydrated glycogen, for this would give for the hydrated form 162/180 × 4,190 = 3,771 cal. The heat of wetting is found to be about 9 cal., hence the heat of combustion of hydrated glycogen in solution is 3,874 cal. The heat of combustion of lactic acid is, according to Meyerhof, 3,601 cal., leaving 273 cal. for the conversion of 1 g. of glycogen into 1 g. of lactic acid. The heat of neutralisation of lactic acid by acid salts is, according to Meyerhof (*loc. cit.*), 19 cal. per g., which leads to the value 273 + 19 = 292 cal. for the heat liberated during contraction and relaxation of a muscle, per g. of lactic acid formed. The total initial heat, given by Hartree and Hill in their balance-sheet (as the result of physical measurement, see preceding abstract) is 296 cal., in close agreement with that calculated above. The salt buffering of the lactic acid is, however, probably only of a temporary character and is replaced by the more efficient buffering by alkali-protein. Meyerhof has shown that the neutralisation of 1 g. of lactic acid by alkali-protein produces 138 cal., or 119 more than that by salts. The whole of these 119 cal. are, however, not produced; according to Hartree and Hill the delayed anaërobic heat production is 74 cal. per g. of lactic acid, so that only about 60% of the lactic acid formed is neutralised by alkali protein (the rest remains neutralised by salts). The delayed heat production, presumably due to a transfer of alkali from protein to acid phosphate and carbonic acid, is the cause of the secondary maximum in the heat production occurring after two and a half minutes (preceding abstract). The velocity of this reaction is independent of the temperature, and thus probably depends on a physical process (rate of diffusion of acid phosphate- and carbonic acid-ions) through the muscle-tissue. This theory demands some special distribution of phosphate and carbonate molecules in the muscle substance, and may be represented by the following scheme:

Contraction (*a*) Glycogen ⟶ lactic acid; (*b*) lactic acid and contractile mechanism produce mechanical response.

Relaxation (*a*) Lactic acid + K_2HPO_4 and $KHCO_3 \longrightarrow$ K lactate + KH_2PO_4 and H_2CO_3.

Anaërobic recovery (*a*) KH_2PO_4 and H_2CO_3 + K protein $\longrightarrow$ $K_2HPO_4 + KHCO_3$ + H protein. G. B.

Products of the Catalytic Hydrolysis of Horse Hair. V. S. Sadikov (*Biochem. Z.*, 1923, **143**, 504—511).—Fractionation of the product obtained by the catalytic hydrolysis of horse hair under pressure yielded the following substances: (1) A peptide anhydride (m. p. 258°) of alanine and leucine to which the formula $C_{21}H_{36}O_4N_4$ or $C_{21}H_{38}O_4N_4$ is ascribed. (2) A peptide anhydride of alanine and leucine (m. p. 260°) of the formula $C_9H_{16}O_2N_2$. (3) A peptide anhydride of leucine and valine (m. p. 246°) of the formula

$C_{11}H_{20}O_2N_2$. (4) Butylalanyl-leucine anhydride, $C_{10}H_{18}O_2N_2$, or its unsaturated derivative, $C_{10}H_{16}O_2N_2$ (m. p. 224°). (5) Diketomethylpiperidine, $C_6H_9O_2N$ (m. p. 196°). (6) A cyclic nitrogen substance, $C_{15}H_{30}N$, of an alkaloidal nature. (7) A substance of the formula $C_{13}H_{20}O_3N_2$ (m. p. 170°). Various other less well characterised derivatives of the nature of diketopiperazines and keto- and diketo-piperidines were obtained. J. P.

Calcium Fixation by Animal Tissues. IX. E. FREUDENBERG and P. GYÖRGY (*Biochem. Z.*, 1923, **142**, 407—416).—A study has been made of the extent to which calcium phosphate and carbonate are formed, when solutions of casein and egg-albumin are treated with sodium phosphate or carbonate at different p_H, and dialysed against calcium chloride. After dialysis the distribution of calcium, phosphate, and fixed carbon dioxide was determined both externally and internally, and the bearing of the results on the process of calcification occurring in animal tissues is discussed. The conclusion is drawn that a reversible fixation of calcium by the tissue proteins takes place. With diminishing metabolic activity, the fixed calcium reacts with phosphate and carbonate to give rise to complex protein–calcium–phosphate–carbonate compounds from which the carbonate is gradually eliminated by the acid nature of the proteins under tissue conditions. The excess of calcium phosphate is then split off, leaving the original active group of the protein free to combine with more calcium (cf. also György, this vol., i, 120). J. P.

The Basis of the Oxidation Theory of Wieland. O. WARBURG (*Biochem. Z.*, 1923, **142**, 518—523).—A criticism of Wieland's views on the mechanism of oxidation. In place of the theory that organic oxidations proceed in two phases, first hydration followed by abstraction of hydrogen by interaction with molecular oxygen, the theory advanced by the author supposes that molecular oxygen is first activated by combination with a catalyst (iron, platinum, or organic catalyst) and then reacts directly with the oxidisable substance. It is argued that Methylene-blue, quinone, etc., do not react like molecular oxygen when substituted for the latter (Wieland, A., 1913, i, 1304), but as activated oxygen, *i.e.*, molecular oxygen + catalyst. The action of hydrocyanic acid in inhibiting oxidations is regarded as opposing Wieland's theory, whilst it receives a ready interpretation on the author's views, since it combines with the catalyst (*e.g.*, iron) and prevents the activation of the oxygen. J. P.

Carnisapidine in Animal Tissues. F. BATTELLI and L. STERN (*Compt. rend. Soc. Biol.*, 1923, **88**, 575—577; from *Chem. Zentr.*, 1923, iii, 1037).—The constituent of animal tissues to which the taste is due is named by the author *carnisapidin*. The amount present in different tissues was determined approximately by dilution of extracts until the taste was just perceptible. The highest content was found in muscles, liver, spleen, and kidneys, lower amounts were found in the thymus, brain, and lungs. G. W. R.

Sarcochromogen in Animal Tissues. F. BATTELLI and L. STERN (*Compt. rend. Soc. Biol.*, 1923, **88**, 679—681; from *Chem. Zentr.*, 1923, iii, 1037; cf. preceding abstract).—Aqueous extracts of animal tissues contain a sarcochromogen which differs from sarcochrome in not being precipitated by metaphosphoric acid. Sarcochromogen is not changed into sarcochrome on evaporation to dryness if the temperature remains below 80°. G. W. R.

The Rôle of Carnisapidin and Sarcochromogen in Animal Tissues. L. STERN and F. BATTELLI (*Compt. rend. Soc. Biol.*, 1923, **88**, 681—683; from *Chem. Zentr.*, 1923, iii, 1037; cf. preceding abstracts).—The occurrence of carnisapidin and sarcochromogen in animal tissues appears to have no direct correlation with metabolic exchange. Certain proteins such as casein give, on treatment with pepsin, substances analogous to sarcochromogen. Carnisapidin and sarcochromogen are easily dialysable, and are not attacked by digestive ferments. Carnisapidin, administered intravenously, is eliminated in the urine, but when administered orally or subcutaneously it is retained or decomposed, probably in the liver. G. W. R.

The Extractives of *Actinia equina*. D. ACKERMANN, F. HOLTZ, and H. REINWEIN (*Z. Biol.*, 1924, **80**, 131—136; cf. A., 1923, i, 1155).—The extractives of *Actinia equina* were subjected to fractionation by Kossel and Kutscher's method. The histidine and arginine fractions have not yet been worked up. In the purine fraction there was obtained adenine, isolated in the form of its picrate. From the lysine fraction there was obtained (1) tetramethylammonium hydroxide (as picrate); (2) a base, identified as pyridylmethylammonium hydroxide (*chloroaurate*, m. p. 252—253°, and *chloroplatinate*); (3) a base of unknown constitution, *actinine*, $C_{13}H_{24}O_5N_2$; from it there were prepared a *chloroaurate*, m. p. 169°, a *chloroplatinate*, dark red, crystalline nodules, decomp. 209°, and a *hydrochloride*, m. p. 207—208°. C. R. H.

The Chemical Differential Diagnosis of Transudates and Exudates. K. HIRUMA (*Biochem. Z.*, 1923, **142**, 506—517).—Exudates contain an albumin precipitable by an acetate mixture at C_H $0{\cdot}36 \times 10^{-4}$, by a phosphate mixture at C_H $0{\cdot}214 \times 10^{-2}$, and by a citrate mixture at C_H $1{\cdot}13 \times 10^{-4}$. Inflammatory cerebrospinal fluids contain the same type of albumin as the exudates formed in pleurisy and in peritonitis. The average sugar content of transudates is 0·115% and of exudates 0·07%, the former being in general above the plasma sugar value of the patient, and the latter somewhat lower. The residual nitrogen of transudates, and the amino-nitrogen and ammonia of both transudates and exudates, are approximately the same as those of the blood, whilst the residual nitrogen of exudates is higher than that of transudates. In nephritis, the residual nitrogen is greater the more marked is the œdematous condition. J. P.

The Distribution of Nitrogen in the Urine of Young Dogs and its Dependence on Diet. F. SERIO (*Biochem. Z.*, 1923, **142**, 440—453).—The distribution of nitrogen in the urine of young dogs kept on a diet rich in fat but poor in, or free from, nitrogen is similar to that of starved animals. The urea is diminished and the ammonia increased due to starvation acidosis. The excretion of amino-acids is not influenced by a low nitrogen diet, but it is lowered on a milk diet. The " urease " method for estimating urea gives lower results than the Mörner-Sjöquist method, a difference which is more marked the smaller the ratio of urea nitrogen to total nitrogen becomes. During the period of pre-mortal increase in the nitrogen excretion, the difference disappears, and it is less apparent on a milk diet. The suggestion is made that the difference is due to allantoin and creatinine being estimated along with urea in the Mörner-Sjöquist method, and that the excretion of these urinary constituents varies under the conditions studied, ceasing during the pre-mortal period. J. P.

Sulphatase. III. The Enzymatic Fission of the Ethereal Sulphates in the Urine of the Horse, Camel, and Dog. J. Noguchi (*Biochem. Z.*, 1923, **143**, 186—189).—By treating horse and camel urine with preparations of sulphatase at 37°, hydrolysis of the ethereal sulphates varying from 60 to 90% was obtained. Similar extensive hydrolysis of the organic sulphates occurred in the urine of a dog to which phenol had been administered. J. P.

Acetonuria and Acidosis. D. Adlersberg (*Biochem. Z.*, 1923, **143**, 527—532).—From a study of the effect of orally administered ammonium dihydrogen phosphate on normal subjects kept on a diet free from carbohydrate, and on diabetic subjects, it is concluded that acidosis diminishes the urinary excretion of ketone substances in these conditions. J. P.

Thymolglycuronic Acid. K. Takao (*Z. physiol. Chem.*, 1923, **131**, 304—306).—According to Blum (A., 1892, 1116), thymol is not excreted by the dog as thymolglycuronic acid, although it is so in man. It is now shown, however, that a very small fraction of it is so excreted by the dog. By treatment with sodium hypochlorite and fuming hydrochloric acid, thymolglycuronic acid in the urine was converted into *dichlorothymolglycuronic acid*, $C_{16}H_{22}O_8Cl_2$, colourless needles, m. p. 118—119°, $[\alpha]_D^{20}-66{\cdot}46°$ ($c = 3{\cdot}9497\%$) (*barium* salt, $[C_{16}H_{21}O_8Cl_2]_2Ba$). W. O. K.

Phosphorus Metabolism in Avitaminosis. K. Morinaka (*Biochem. Z.*, 1923, **142**, 381—384).—The phosphorus content of the livers of avitaminosed rats to which sodium phosphate, lecithin, or phosphoprotein has been administered does not differ appreciably from that of the livers of similarly fed normal rats. The conclusion is drawn that in avitaminosis the soft tissues do not lose their power of phosphorus retention. J. P.

The Kephalin and Lecithin Content of the Brain in Avitaminosis. H. Naito (*Biochem. Z.*, 1923, **142**, 385—392).—The percentage content of kephalin and lecithin in the brains of avitaminosed rats and guinea-pigs does not depart appreciably from normal, although there is a diminution in the total mass of brain-tissue. J. P.

The Lecithin Content of the Brain and Liver of Normal and Avitaminosed Pigeons after Forced Lecithin Feeding. H. Naito (*Biochem. Z.*, 1923, **142**, 393—397).—Lecithin feeding slightly increases the amount of the lipoid found in the livers of normal, but not in the livers of avitaminosed pigeons. The lecithin of the brain is not affected in either case. It is concluded that in the avitaminosed liver, phosphorus compounds other than lecithin increase at the expense of the latter (cf. Morinaka, above). J. P.

Fat Metabolism in Avitaminosis. IV. The Gaseous Metabolism of Starved Avitaminosed Rats during Digestion and after Adrenaline Injection. K. Asada (*Biochem. Z.*, 1923, **143**, 387—398).—The oxygen consumption of partly and completely avitaminosed rats is sub-normal, both during a period of starvation and while a vitamin-free meal is being digested. The extent of the increase observed under the latter conditions compared with the requirements of the starved animals varies inversely with the severity of the avitaminosis. Adrenaline injections produce a greater increase in oxygen consumption in avitaminosed than in normal rats. A discussion is appended of the earlier results obtained in the study of carbohydrate and fat metabolism in avitaminosis. J. P.

Uric Acid and Allantoin Metabolism in Avitaminosis. A. Adachi (*Biochem. Z.*, 1923, **143**, 408—422).—In avitaminosis, the excretion of allantoin in dogs shows no notable variations, whilst that of uric acid is variable and may show transitory increases. In long-continued avitaminosis, the uric acid excretion is markedly increased and may reach values three times those obtained in normal animals. It is concluded that an increased consumption of nucleins occurs in the later stages of avitaminosis. J. P.

The Pharmacology of the Rare Earths. I. Cerium. S. Hara (*Arch. expt. Path. Pharm.*, 1923, **100**, 217—253).—In general, cerium bears a close resemblance to aluminium and to the heavy metals in its pharmacological action. Proteins are precipitated by moderate but not by strong concentrations of its salts. C. R. H.

The Pharmacology and Toxicology of Carbon Tetrachloride. P. D. Lamson, G. H. Gardner, R. K. Gustafson, E. D. Maire, A. J. McLean, and H. S. Wells (*J. Pharm. expt. Ther.*, 1923, **22**, 215—288).—A comprehensive study of the pathological effects following administration to dogs of carefully purified carbon tetrachloride. Oral administration produced only slight and transitory symptoms unless accompanied or preceded by administration of fats or alcohol. When given intravenously, it is lethal in doses of 0·154 c.c. per kg. body-weight.

The pathology of carbon tetrachloride poisoning consists essentially (apart from local irritant effects such as bronchitis following inhalation) in damage done to the liver, one of the first indications of which is the appearance of abnormal amounts of bilirubin in the blood. C. R. H.

The Rôle of certain Carbohydrates in the Organism. E. O. FOLKMAR (*Bibliotek laeger*, 1923, **115**, 120—125; from *Chem. Zentr.*, 1923, iii, 1291).—With continued intravenous injection of pentoses in small amounts at a rate comparable to intestinal absorption, approximately one-half is excreted in the urine. Galactose can be assimilated at the daily rate of 1—2 g. per kg. of live weight without glycosuria or appreciable increase in blood-sugar. Maltose is well utilised, after becoming hydrolysed by maltase. There is an appreciable retention of sucrose in certain circumstances; invertase is, however, not present in blood. Raffinose is completely excreted. The small amounts of ethyl alcohol normally present in blood are attributed to casual decomposition of carbohydrates and not to the action of an alcoholase. G. W. R.

The Influence of Oral Administration of Dextrose on the Blood-sugar and on Glycosuria in Healthy Individuals. G. CONSTAM (*Biochem. Z.*, 1923, **143**, 75—104).—The elimination of sugar in the urine is best followed by estimating the amount excreted in unit time. Observations based purely on changes in concentration do not give dependable results. In normal individuals a mixed meal is followed by a definite glycosuria. Tap water produces a dilution glycosuria which reaches a maximum in about one hour. The assimilation limit for sugar in the same individual is variable and is higher after five hours' than after fourteen hours' abstention from food, whilst the assimilation capacity varies in the opposite sense. In the cases quoted, the tolerance lay between 100 and 150 g. of dextrose in 500 c.c. of water after five hours, and between 20 and 30 g. in the same volume after fourteen hours' starvation; less concentrated solutions caused dilution glycosuria which diminished with increasing concentration of dextrose until the assimilation limit was reached, when a true glycosuria supervened. The blood-sugar reaches its maximum about half an hour before the urinary sugar. The suggestion is made that the power of the organism to raise the sugar tolerance is a protective mechanism which prevents loss of sugar during periods of diminished rate of assimilation. J. P.

A New Method of Preparing *s*-Diphenylguanidine. Its Pharmacological Effects. O. RIESSER (*Z. physiol. Chem.*, 1923, **131**, 204—213).—Diphenylguanidine is formed together with a small amount of triphenylmelamine when dicyanodiamine is heated with aniline hydrochloride at 190—200°. It crystallises from alcohol in white needles, m. p. 145—148°, and forms a chloroaurate. The pharmacological action of this substance has been investigated. It increases the reflex irritability and also causes central paralysis. In warm-blooded animals, it causes death by arrest of the respiration. It produces progressive paralysis when applied to isolated frog's muscle. W. O. K.

Chemistry of Vegetable Physiology and Agriculture.

Biology of *Bacillus coli communis*. Attempts at "Dysmutation." O. Fernández and T. Garmendia (*Anal. Fis. Quim.*, 1923, **21**, 481—492).—A study of the effect of various reagents on the fermentation of dextrose by *B. coli communis*. Dysmutation consists in the formation of alcohol, acetic acid, and glycerol from sugars through the acetaldehyde formed as an intermediate stage undergoing the Cannizzaro reaction yielding ethyl alcohol and acetic acid. The dysmutation effect, as judged by the amount of acetic acid produced from dextrose was considerable in the case of cultures to which sodium hydrogen carbonate was added. Less appreciable effects were produced where amino-acids were added. G. W. R.

The Decomposition of *d*-Glucosamine by Micro-organisms. K. Takao (*Z. physiol. Chem.*, 1923, **131**, 307—318).—*Bacillus subtilis*, grown on a synthetic medium, with or without the addition of peptone, in presence of *d*-glucosamine forms from the latter succinic acid and a small quantity of lactic acid. If a modified medium is used in which no carbonate is present, lactic acid, but no succinic acid is formed. *B. coli* also forms lactic acid and succinic acid, whilst *B. prodigiosus* forms only lactic acid when grown on a synthetic medium containing *d*-glucosamine. W. O. K.

The Sulphur Cycle in Soil. (The Biology of Thiosulphate Bacteria.) G. Klein and A. Limberger (*Biochem. Z.*, 1923, **143**, 473—483).—The thiosulphate bacteria present in soil can be cultured aërobically in inorganic or organic media, and are capable of oxidising the various inorganic compounds of sulphur which occur in soils to sulphuric or polythionic acids. They also oxidise the sulphur of cystine, and to a less extent that of albumin and nuclein to sulphuric acid. Sulphur is an intermediate product in all cases and may separate in a crystalline condition. In the presence of potassium nitrate, the oxidation is accompanied by the formation of nitrite and ammonia, whilst the presence of ammonium chloride gives rise to the former. The spores of the bacteria are found in water and air as well as in the soil. Considerable importance is attached to the part played by these bacteria in the sulphur cycle occurring between the plants and animals. J. P.

The Influence of Oxygen on the Assimilatory and Dissimilatory Activity of Yeast. III. The Behaviour of Added Alcohol in a Yeast Suspension. H. Lundin (*Biochem. Z.*, 1923, **142**, 454—462).—Arising from the author's previous work (A., 1923, i, 1268), a study has been made of the capacity of aqueous yeast suspensions, containing no carbohydrate or source of nitrogen, to assimilate added ethyl alcohol both under normal conditions and in the presence of excess of oxygen. In contrast to the results

obtained with "nascent" alcohol formed from carbohydrate which is assimilated both with and without excess of oxygen, added alcohol is only assimilated when a stream of oxygen is passed through the solution. Carbohydrate alone is formed and the yeast-cells increase in mass, but not in numbers. On the assumption that no direct oxidation of part of the added alcohol occurs (*loc. cit.*), it is shown that a utilisation of a portion of the assimilated carbohydrate takes place which runs parallel with its formation. A summary is given of the present results, together with the author's earlier observations.
J. P.

The Influence of Oxygen on the Assimilatory and Dissimilatory Activity of Yeast. IV. The Behaviour of certain Organic Acids. H. Lundin (*Biochem. Z.*, 1923, **142**, 463—492).—The methods already described (cf. preceding abstract) have been extended to a study of the capacity of a yeast suspension to assimilate various organic acids. The sodium and ammonium salts of citric, malic, tartaric, and succinic acids are not assimilated even in the presence of an excess of oxygen, and the added salts are without influence on the course of self-fermentation of the yeast. Potassium acetoacetate is assimilated more especially in concentrations of about 1%. Potassium carbonate is formed at the same time, and unless the p_H is adjusted the process is arrested. It is supposed that acetone and carbon dioxide are formed, and the former, in the nascent state, is assimilated to form carbohydrate when an excess of oxygen is provided. The newly-formed carbohydrate may then undergo oxidation. As in the previous experiments, carbohydrate alone is formed, and no alteration in the protein constituents of the yeast is noted. J. P.

Carboligase. VI. A New Type of Change of Acetaldehyde by Fermenting Yeast. C. Neuberg and E. Reinfurth (*Biochem. Z.*, 1923, **143**, 553—565).—The addition of acetaldehyde to dextrose, lævulose, or sucrose undergoing fermentation by top- or bottom-yeasts, leads to the formation of optically active acetylmethylcarbinol, $CH_3\cdot CH(OH)\cdot CO\cdot CH_3$. This "acyloin" synthesis also occurs in cell-free fermentations. Part of the acetaldehyde undergoing condensation arises from the sugar (cf. A., 1923, i, 973).
J. P.

The Fermentation Co-enzyme (Co-zymase) of Yeast. I. H. v. Euler and K. Myrbäck (*Z. physiol. Chem.*, 1923, **131**, 179—203).—Yeast was obtained free from co-enzyme by grinding up the dry yeast with water, centrifuging, again grinding up with water, and centrifuging. The product was then diluted to a given volume with water. A solution of co-enzyme was obtained by boiling yeast with water for a few minutes and if necessary filtering. The co-enzyme is completely precipitated by 50—80% alcohol.

The effect of variation of the p_H on the rate of fermentation of dextrose by various yeasts has been investigated (cf. Euler and Heintze, A., 1920, i, 513). Fermentation is most rapid at p_H 6·2—6·8. Fresh yeast preserves its maximum fermentation over a greater range of p_H than dried yeast. For autofermentation, the optimum p_H is 5—6. The observation of Harden that the activity is very dependent on the amount of phosphate-ion present is confirmed. The activity is a maximum at a certain optimum phosphate content. If there is a constant amount of washed yeast present, then the activity is at first approximately proportional to the amount of the co-enzyme present, and gradually, with increasing co-enzyme, becomes less than required by this relation, and ultimately is approximately constant. Similarly, if the co-enzyme is constant, the activity is at first approximately proportional to the amount of washed yeast, but with large amounts of washed yeast ultimately constant. In presence of constant quantities of washed yeast and of activator, the fermentation increases with increase in the amount of dextrose present to a maximum, and it then decreases. In the absence of phosphate, arsenate does not cause marked fermentation. The co-enzyme is apparently stable in aqueous solution for at least twenty-three hours, and is dialysable through a collodion membrane. It is precipitable by lead acetate and it is not identical with vitamine-*D* as it is not contained in orange juice or malt extract.

W. O. K.

Is Lactic Acid Produced in Alcoholic Fermentation? A. FERNBACH and M. SCHOEN (*Compt. rend. Soc. Biol.*, 1923, **89**, 475—477; from *Chem. Zentr.*, 1923, iii, 1035).—From the products of the alcoholic fermentation of sucrose in the presence of calcium carbonate, *d*- and *l*-lactic acid were isolated as the zinc salts. The *d*-lactate was in excess.

G. W. R.

Formation of Organic Acids by *Sterigmatocystis nigra* [*Aspergillus niger*] in Unbalanced Media. M. MOLLIARD (*Compt. rend.*, 1924, **178**, 41—45).—Previous work (A., 1922, i, 611) is continued from a more quantitative point of view. Known weights of the fungus were allowed to grow in presence of media of different composition (varying the proportions of sucrose and inorganic salts), and the amounts of citric and gluconic acid produced determined from time to time. It is shown that reduction of the proportion of nitrogen present favours the production of gluconic acid, reduction of the other inorganic constituents of the culture medium (phosphorus, potassium, magnesium, iron, and zinc) causing the formation of oxalic and citric acids.

E. E. T.

Antiseptic Action of the Zinc Chloride Salt of Aniline. J. W. HOWARD and F. D. STIMPERT (*J. Amer. Chem. Soc.*, 1923, **45**, 3106—3108; cf. A., 1899, i, 40; 1911, i, 191; 1912, i, 363).—The salt $(NH_2Ph)_2,ZnCl_2$ was formed by intimately mixing aniline and fused zinc chloride; it melts at 255°, and is soluble to the extent of 0·64 g. in 100 c.c. of water at 20°, 0·87 g. in 100 c.c. of 0·4% hydrochloric acid at 20°, and 0·066 g. in 100 c.c. of 95% alcohol at 20°. It is readily decomposed by *N* sodium hydroxide or boiling water. Tests with a culture of *Staphylococcus aureus* indicate that the salt has greater bactericidal action than either aniline or zinc chloride, the respective relative efficiency being approximately 10 : 7½ : 2.

F. B.

The Evolution of Phosphorus during Germination. M. H. VAN LAER and R. DUVINAGE (*Bull. Soc. chim. Belg.*, 1923, **32**, 355—357).—Determinations of the amount of phosphorus and its distribution in the various parts of the grain have been carried out in the case of barley, the grains themselves, the straw, endosperm, seeds, and roots being examined. The grains were first soaked and then allowed to germinate at 15°. The following facts were established: (1) soaking involves an elimination of about 10% of phosphorus; this takes effect both on the straw and on the endosperm; (2) during germination, a migration of phosphorus from the endosperm to the embryo occurs; (3) kilning of the grain has little effect. In the raw barley, the embryo is rich in phosphorus whilst the straw is poor; during germination the phosphorus content of the endosperm diminishes. It is shown that in the embryo, although the amount of phosphorus is greatly increased, the percentage amount remains practically constant, owing to the development of the embryo itself. During germination, a portion of the phosphorus is rendered soluble, and it is this soluble phosphorus which migrates to the embryo. F. G. P.

Theory of Carbonic Acid Assimilation. WO. OSTWALD (*Kolloid Z.*, 1923, **33**, 356—368).—A theoretical paper in which the experimental work on this subject is briefly summarised and the points are noted which must be covered by any theory of assimilation. The following new hypothesis is developed. The primary process of assimilation is a photo-autoxidation, which consists in the formation of a lipoid peroxide sparingly soluble in water. The second process is the formation of an additive compound of albumin and carbon dioxide; this is followed by the interaction of the lipoid peroxide and the albumin–carbon dioxide complex with water in which oxygen is given up, whereby, either, according to Wislicenus's reaction, carbonate is reduced by hydrogen peroxide, or through the formation of an albumin–carbon peroxide compound the reduction through formic acid to formaldehyde takes place. The fourth process consists in the recombination of an oxygen atom with the lipoid oxide to re-form the lipoid peroxide. This combination takes place in the presence of light in chlorophyll-bearing cells and brings the system back to its initial condition. The lipoid peroxide appears to be the "photochemical motor" of the assimilation process. The photochemical reaction in assimilation is not a photo-reduction, but a photo-autoxidation. The whole of the reactions take place in the interface albumin–lipoid, and all work in such a way that the interface is maintained. Chlorophyll appears not to take part in the assimilation process; stoicheiometrically its action probably consists in a physico-chemical promotion of the photo-autoxidation of the lipoid. J. F. S.

Composition of Vegetable Juices obtained by Pressure. G. ANDRÉ (*Compt. rend.*, 1924, **178**, 114—116).—Previously (*ibid.*, 1922, **175**, 286) it was shown that when certain fruit juices are filtered through porous porcelain impregnated with collodion, inorganic, but not organic, phosphorus passed through, whilst the fraction of the total nitrogen passing through was of the same order as the fraction not coagulable by heating at 100°. The relative proportions of filtrable, coagulable, and total nitrogen remain almost constant during growth in the case of potatoes; with increase of filtration pressure, the ratio inorganic phosphorus : total phosphorus increases, that of total phosphorus to total nitrogen remaining constant. E. E. T

Wood Sap. I. Presence of Enzymes in Wood Sap. II. Variations in the Amount of Oxydases in Wood Sap during the Bleeding Period. E. PH. VOTCHAL (*Pamphlet*, Moscow, 1916).—The sap in the outer annual rings in healthy trees is completely sterile. Oxydases and diastases are shown to be present. The maximum oxydase content is reached when trees break into leaf. G. W. R.

The Anthocyans in Norton and Concord Grapes. The Chemistry of Grape Pigments. R. J. ANDERSON (*J. Biol. Chem.*, 1923, **57**, 795—813).—The pigments present in two varieties of American grapes, namely, Norton (*Vitis æstivalis*, *V. labrusca*) and Concord (*V. labrusca*), have been examined by the methods of Willstätter and Zollinger (A., 1915, i, 285; 1917, i, 47). The same anthocyanin chloride, $C_{23}H_{25}O_{12}Cl,3H_2O$, has been isolated from both varieties. On hydrolysis, it yields dextrose and an anthocyanidin chloride, $C_{17}H_{15}O_7Cl,1\frac{1}{2}H_2O$. The substances are identical in composition with the oenin and oenidin chlorides obtained by Willstätter and Zollinger from European grapes (*V. vinifera*), but they differ from these substances in that the anthocyanidin contains only one methoxyl group, whereas oenidin contains two. The colour reactions are, moreover, different. The anthocyanin gives with ferric chloride in aqueous solution a purple colour which quickly fades to light brown, and in alcoholic solution an intense blue which changes to purple and finally to wine-red; the anthocyanidin gives with the same reagent both in aqueous and alcoholic solution a momentary purple colour fading to an almost colourless or faintly yellow solution. Evidence of the presence of a diglucoside has also been obtained. E. S.

Constituents of *Milletia taiwaniana*, Hayata. T. KARIYONE, K. ATSUMI, and M. SHIMADA (*J. Pharm. Soc. Japan*, 1923, No. **500**, 739—746).—Nagai (*J. Tokyo Chem. Soc.*, 1902, **23**, 744) isolated rotenone as one of the poisonous constituents of *Milletia taiwaniana*, Hayata, produced in Formosa. Later, Ishikawa (A., 1918, i, 94) isolated anhydroderride from the mother-liquor of rotenone and pointed out that rotenone was not identical with tubotoxin, a poisonous constituent of *Derris elliptica* (*J. Pharm. Soc. Japan*, 1923, No. **491**, 10). The authors have established the identity of rotenone and tubotoxin from the coincidence of the following properties: Crystalline forms (rhombic plates from hot alcohol or needles from benzene); m. p. 163°; (mixed sample gave the same m. p.), empirical formula, $C_{18}H_{18}O_5$, $[\alpha]_D^{20}$ $-236\cdot5°$ to $-244°$, oxime,

m. p. 245°, and phenylhydrazone, m. p. 255°. The authors have retained the name rotenone, as it was the first proposed. From crude rotenone, a white, wax-like, amorphous substance was isolated; it has m. p. 80°, acid value 15·85, saponification value 33·92 (118·70 after acetylation), and iodine number 17·02. K. K.

The Acids and Red Colouring Matter of the Horned Poppy (*Glaucium luteum*). H. Schmalfuss (*Z. physiol. Chem.*, 1923, **131**, 166—167).—The following acids have been obtained from the juice expressed from the horned poppy: citric acid, 25·82%, lactic acid, 18·24%, acetic acid, 11·88%, succinic acid, 1·99%, fumaric acid, 21·59%, malic acid, 13·50%, anhydromalic acid, 5·92%, βγ-dihydroxy-Δ^{β}-butene-αδ-dicarboxylic acid, 1·07%, the steric configuration of which has not been determined, and traces of formic acid. The hydrochloric acid extract of the pulp left contained fumaric acid 34·33%, malic acid 12·53%, and oxalic acid 53·14%. No trace of maleic acid could be detected in the plant. The red colouring matter appears to be a lipochrome. W. O. K.

Lipase in Sunflower (*Helianthus annuus*) Seeds. F. Traetta-Mosca and F. Milletti (*Ann. Chim. Applicata*, 1923, **13**, 270—288).—The authors give a summary of the literature dealing with the lipolytic enzymes of seeds and describe experiments which show that sunflower seeds exhibit lipolytic activity, this being only slight in the quiescent seeds, but becoming more intense in germinating and also in de-fatted seeds. Experiments with oleic acid and glycerol yield results showing that the lipase of sunflower seeds exerts also a synthetic action. Acid is liberated in gradually increasing proportions from linseed, cotton-seed, and castor oils by the agency of sunflower seeds. T. H. P.

Phosphate Behaviour in Soils. J. S. Burd and J. C. Martin (*Science*, 1923, **58**, 227—228).—By use of the authors' method (*J. Agr. Sci.*, 1923, **13**, 265) for the extraction of what is probably the true soil solution, it has been shown that after a volume of solution equal to the amount of water initially contained in the compacted soil has been removed, the solutions obtained from a second displacement of the same mass of soil with an equal amount of water have decreasing total concentrations of electrolytes, but the phosphate concentrations increase. Thus, at the approach of the end of the growing season, the diminished total concentration in the soil solution is probably accompanied by a tendency towards enhancement of the concentration of phosphate. An apparent result of this effect has been observed, although it may easily become masked by experimental error in soils of low total concentration or by increased absorption of phosphate by the plant in the later stages of growth. A. A. E.

Organic Chemistry.

The Combustion of Methane to Formaldehyde. H. TROPSCH and O. ROELEN (*Brennstoff-Chem.*, 1924, **5**, 37—42).—A gas mixture containing methane and oxygen was passed through a quartz tube (without a catalyst), heated in an oven, and the formaldehyde produced absorbed in water and determined titrimetrically. The effect of varying the methane : oxygen ratio in the gas, the diameter of the tube, the reaction temperature, and the gas velocity through the tube, was studied. The yield of formaldehyde first increases with increasing gas velocity (the other factors being kept constant), reaches a maximum, and then decreases, a characteristic curve being obtained by plotting the results graphically. In the experiment in which the highest yield of formaldehyde was obtained the gas velocity was as high as 20 m. per sec. The tubes employed had cross-sectional areas of 63·5, 13·5, and 1·4 sq. mm., respectively, and the highest yields were obtained with the second of the three. If the oxygen content of the gas used is maintained constant (about 16—19%) and the methane content is varied, the highest concentration of formaldehyde in the resulting gas is obtained with a methane : oxygen ratio of 1 : 1, as required by theory. When working at high temperatures, the maximum is only obtained by starting with a high gas velocity and gradually diminishing it, much lower results being obtained by working conversely. With increasing reaction temperature, the absolute quantity of formaldehyde produced increases, but the yield per unit of methane decomposed diminishes. The highest yield of formaldehyde, viz., 5·96% of the methane treated, was obtained with a gas containing 1·2% of methane and 19·4% of oxygen, whilst a maximum yield of 70% of the methane decomposed was obtained at a reaction temperature of 700°, showing that formaldehyde is formed as the principal product in the action of oxygen on methane. Discrepancies between the present results and those of previous workers are discussed. W. T. K. B.

The Influence of some Non-inflammable Vapours of Organic Liquids on the Limits of Inflammability of Mixtures of Methane and Air. W. P. JORISSEN and J. VELÍŠEK (*Rec. trav. chim.*, 1924, **43**, 80—86).—The limits of inflammability of mixtures of methane and air are found to be 5·4% and 14·1% of methane. These limits are considerably modified by the presence of vapours of non-inflammable liquids. In presence of 0·7 to 0·8% of perchloroethylene, the limits are 7·35 and 10·15%; with 0·7 to 0·8% of tetrachloroethane, 7·15 and 9·15%; with 1% of pentachloroethane, 5·95 and 10·3%. In presence of 20% of dichloroethylene, 5% of trichloroethylene, or of 12·2% of carbon tetrachloride explosion is entirely inhibited, whilst with 8·5% of carbon tetrachloride the limits are 9·0 and 9·9% of methane.

E. H. R.

The Cracking Process of Burton. H. I. WATERMAN and H. J. W. REUS (*Rec. trav. chim.*, 1924, **43**, 87—92).—It has been claimed that condensation under pressure in the oil-cracking process leads to the production of distillates free from unsaturated hydrocarbons. The authors are unable to verify this claim. [Cf. *B.*, 1924, 207.] E. H. R.

The Generation of Ethylene from Alcohol. T. HISAMURA and Y. IMAOKA (*Kwaken Hôkoku*, 1923, No. 7, 1—21).—Ethylene is prepared by passing alcohol vapour over "adsol" electrically heated at 390—400°, the yield being about 83%. (Adsol is a product used for drying air and is prepared from Japanese acid clay by pressing and burning; cf. Japan. Pat. 42368.) The rate of passing alcohol is 60—80 c.c. (in liquid) per hour, the thickness of the layer of the catalyst is 7 cm., and the resulting gas contains 98% of ethylene. After ten hours' passage of the vapour the yield decreases to 71%; the catalyst may, however, be re-activated by heating it for about thirty minutes at 650—700° in a current of air. K. K.

The Additive Power of Iodine with regard to Ethylenic Compounds. E. ANDRÉ (*Bull. Soc. chim.*, 1923, **33**, [iv], 1641—1647).—The author has studied the action of iodine in various solvents on olive, sesamé, poppy, and cod-liver oils, also on *iso*heptene and phenylbutylene. The results obtained are compared with the iodine values furnished by Hanus' method, and show that the element itself is fairly active. Least activity is shown by the violet solutions in carbon tetrachloride and carbon disulphide; the brown solution in acetic acid and the violet-red chloroform solution exhibit much greater activity, the latter in some cases fixing 97% of the amount used in an iodine value determination. A second series of experiments, in which the iodine concentration was in each case $N/10$, gave similar results from the comparative point of view, although the ratio of iodine fixed to iodine value decreases considerably on dilution. The additive action in respect of ethylenic compounds seems to be capricious, as the same reactants under apparently similar conditions yielded discordant results in many cases. H. J. E.

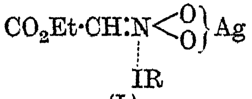
Aliphatic Nitro-compounds. XIV. The Preparation of Nitroacetic Esters and the Alkylation of their Silver Salts. W. STEINKOPF [and, in part, E. A. HAUGEN, A. SCHKADE, T. HÖPNER, and B. NOWY] (*Annalen*, 1923, **434**, 21—34).—Ethyl nitroacetate, b. p. 97°/13 mm., is prepared by passing dry hydrogen chloride into a solution of the acid, or a suspension of its potassium salt, in absolute alcohol at 0°, or by the gradual addition of concentrated sulphuric acid to a solution of the acid in alcohol at —15°. Its ammonium salt, long needles, has m. p. 124° (cf. Bouveault and Wahl, A., 1901, i, 4). The silver salt, if prepared from the pure ammonium salt, may be kept for a week before it becomes discoloured; it darkens at 40°, and decomposes at 117—119°. The following esters are similarly prepared: methyl, b. p. 106—110°/31 mm.; *propyl*, b. p. 105°/18 mm.; iso*propyl*, b. p. 92·2—

93·2°/12 mm. (*ammonium* salt, m. p. 107—109°); iso*butyl*, b. p. 111·5—112·5°/15 mm. (*ammonium* salt, m. p. 110—112°); iso*amyl*, b. p. 122—123°/16 mm. (*ammonium* salt, m. p. 112—115°).

The silver salt of ethyl nitroacetate (1 mol.) is gradually added to methyl iodide (2 mols.) at or below 0°. The product contains ethyl α-nitropropionate (cf. Steinkopf and Supan, A., 1911, i, 4) and *ethyl nitroacetate* aci*methyl ether*, $CO_2Et\cdot CH{:}NO_2Me$, a colourless liquid, b. p. 84°/2·5 mm., which gives a red coloration with ferric chloride, and is decomposed by means of concentrated hydrochloric acid at 70° into formaldehyde and *iso*nitrosoacetic acid. Similarly, the use of ethyl iodide leads to the formation of ethyl α-nitrobutyrate (cf. Schmidt and Widmann, A., 1909, i, 453) and *ethyl nitroacetate* aci*ethyl ether*, a colourless liquid, b. p. 81°/3 mm. These *aci*nitroethers, in which, in addition to the nitro group, there is only one other negative radical, are quite stable, and do not show any tendency to undergo isomerisation to the *C*-alkyl derivative. The view of Hantzsch and Voigt (A., 1912, i, 151), that two such radicals are necessary to stabilise an *aci*nitroether, is therefore incorrect.

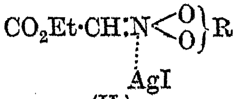
It is probable that the compound, m. p. 114°, obtained by Ratz (A., 1906, i, 238) from silver nitroacetamide and ethyl iodide is an *aci*nitroether of the formula $CH_2ON\cdot CH{:}NO_2Et$.

During the action of methyl iodide on silver ethyl nitroacetate (above), the following phenomena are observed. If the salt is added at about −20°, it dissolves immediately to give a deep brown solution, the colour of which rapidly gives place to a white opalescence; silver iodide is then precipitated. If the addition is made at −60°, there is no reaction; as the mixture is allowed to become warm the solid is gradually dissolved, to give a colourless solution. This is stable over quite a wide range of temperature. Suddenly, however, the solution becomes dark. The brown colour then disappears as before, and silver iodide makes its appearance. It is supposed that in the colourless solution there is a molecular



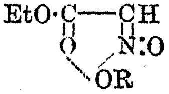
$$\underset{\vdots\atop \mathrm{IR}}{\mathrm{CO_2Et\cdot CH{:}N}}\!\left<\begin{matrix}\mathrm{O}\\ \mathrm{O}\end{matrix}\right\}\mathrm{Ag}$$

(I.)



$$\underset{\vdots\atop \mathrm{AgI}}{\mathrm{CO_2Et\cdot CH{:}N}}\!\left<\begin{matrix}\mathrm{O}\\ \mathrm{O}\end{matrix}\right\}\mathrm{R}$$

(II.)



$$\begin{array}{lcl}\mathrm{EtO\cdot C} & \text{——} & \mathrm{CH}\\ \quad\| & & \;\|\\ \quad\mathrm{O} & & \mathrm{N{:}O}\\ & \diagdown\;\diagup & \\ & \mathrm{OR} & \end{array}$$

(III.)

compound (I); the appearance of the brown coloration is due to a kind of double decomposition, resulting in the formation of a halochromic complex (II), from which the removal of silver iodide gives stereoisomeric *aci*nitroethers,

$$\begin{matrix}\mathrm{CO_2Et\cdot CH}\\ \quad\;\;\|\\ \quad\mathrm{O{:}N\cdot OR}\end{matrix}$$

and

$$\begin{matrix}\mathrm{CO_2Et\cdot CH}\\ \quad\;\;\|\\ \quad\mathrm{RO\cdot N{:}O}\end{matrix}$$

These are then stabilised, the former by isomerisation to the *C*-alkyl derivative, and the latter by "conjugation" (III) (Hantzsch and Voigt, *loc. cit.*).

iso*Propyl mercuri*aci-*nitroacetate anhydride*, $CO_2Pr^{\beta}\cdot C{<}^{NO}_{Hg}{>}O$, is obtained by the addition of concentrated mercuric chloride solution to an aqueous solution containing sodium acetate and the *aci*ammonium salt of *iso*propyl nitroacetate; the iso*butyl* and iso*amyl* derivatives are prepared in a similar manner. These compounds resemble ethyl nitroacetate *aci*mercurianhydride (cf. Prager, A., 1913, i, 5); they are white solids, which sublime when heated, and are soluble in dilute sodium hydroxide solution, potassium cyanide solution, or hydrochloric acid. The solution in alkali does not react with potassium iodide. The action of mercuric chloride on potassium or ammonium nitroacetate gives, apparently, a heterogeneous product, which does not sublime on being heated, but decomposes violently.

Diammonium nitroacetate, $NH_4O{\cdot}CO{\cdot}CH{:}NO_2{\cdot}NH_4$, a white solid, is obtained from ammonia and nitroacetic acid in dry ethereal solution; the *disilver* salt is also prepared.

Condensation could not be effected between ethyl nitroacetate and benzaldehyde, piperonal, or anisaldehyde, using methylamine, ethylamine, amylamine, or piperidine as catalysts. W. S. N.

The Formation of Ethyl Chloride from Ethylene and Hydrogen Chloride. E. Berl and J. Bitter (*Ber.*, 1924, **57**, [*B*], 95—99).—The union of ethylene with hydrogen chloride in the presence of aluminium chloride is effected most advantageously at 130—170°, but the slowness of the reaction renders prolonged contact with the catalyst necessary for the production of good yields of ethyl chloride; the latter substance is absorbed from the products of the reaction by active charcoal.

Ethyl chloride is analysed by passing it through a very narrow quartz tube heated at 900°, absorption of the hydrogen chloride by sodium hydroxide, and titration of the chloride by *N*/10-silver nitrate. The process is applicable to dichloroethylene, but not to chloroform or benzyl chloride. H. W.

Chlorination of Carbon Chains. Chlorination of Normal Butyl Alcohol. H. Gault and R. Guillemet (*Bull. Soc. chim.*, 1923, **33**, [iv], 1792—1801).—The chlorination, at definite temperatures in diffused daylight, of *n*-butyl alcohol has been studied, using iron (steel wire) as a catalyst, and different methods of procedure, viz., either bubbling chlorine through the alcohol, or (counter-current method) allowing the latter to run in a helical path down a vertical tube up which the chlorine passed. A comparative chlorination was carried out, in each case, in absence of the catalyst. The latter does not affect the yield of main product, but diminishes the amounts of by-products. These are produced in larger amount in cold than in hot chlorinations, owing to the formation of acetals in the latter case, and resulting restriction of action.

Chlorination, at temperatures not higher than 10°, by the bubbling method, gave, in presence of iron, a single product (corresponding with 18—20% of the alcohol used), shown to be the *dibutyl acetal* of a *chlorobutaldehyde*, $C_4H_7Cl(OBu)_2$, a colourless liquid, b. p. 125°/15 mm. The latter in presence of hydrogen chloride in a closed tube at 120—130° was partly converted into an unstable *liquid* (b. p. 80—90°/15 mm., with loss of hydrogen chloride) which reduced Fehling's solution and was converted by alcoholic hydrogen chloride into an *acetal*, $CHMeCl\cdot CH_2\cdot CH(OEt)_2$(?).

Chlorination by the bubbling method (using the catalyst) at 40—80° gave the *dibutyl acetal* of a *dichlorobutaldehyde* (yield, 50% of alcohol taken; b. p. 140—142°/15 mm.). This acetal, although unaffected by diluted mineral acids at the ordinary pressure, was partly converted, on heating at 125° in presence of hydrogen chloride, into a *liquid* (b. p. 105—110°/15 mm.) which reduced Fehling's solution, and lost hydrogen chloride on being distilled. The acetal, on being heated with acetic anhydride in a closed tube at 200°, was partly converted into *n*-butyl acetate and a *dichlorobutylidene diacetate* (b. p. 124—129°/15 mm.) (?), and with chromic acid yielded butyric acid and a *butyl dichlorobutyrate* (b. p. 210—215°).

The counter-current method gives less homogeneous products than are given by the bubbling method. E. E. T.

Oleic Alcohol. Y. TOYAMA (*Chem. Umschau*, 1924, **31**, 13—16; cf. A., 1922, i, 895).—The acetyl ester of the oleic alcohol obtained from rabukazame oil gave on oxidation with potassium permanganate nonylic acid and acetylhydroxynonylic acid. This result, coupled with the previously established fact that the same substance gives the acetyl ester of normal octadecyl alcohol on hydrogenation, establishes the formula, $CH_3\cdot[CH_2]_7\cdot CH\colon CH\cdot[CH_2]_7\cdot CH_2\cdot OH$, for oleic alcohol. It is accordingly identical with the alcohol obtained from ethyl oleate. It has d_4^{15} 0·8523, d_4^{20} 0·8491, d_4^{40} 0·8367; n_D^{15} 1·4626, n_D^{20} 1·4607, n_D^{40} 1·4530, b. p. 333—335°/760 mm., 197°/10 mm., 209°/15 mm., 228°/30 mm. Elaidic alcohol has m. p. 35·0—35·5°, d_4^{40} 0·8338, n_D^{40} 1·4522, b. p. about 333°/760 mm., 198°/10 mm., 210°/15 mm., 229—230°/30 mm. These two isomeric alcohols are very stable and show no tendency to change into one another on heating or acetylation. They are sharply differentiated from one another by their melting points. H. C. R.

Equilibria between some Glycols and their Acetone Compounds. J. BÖESEKEN and P. H. HERMANS (*Rec. trav. chim.*, 1923, **42**, 1104—1110).—The authors have prepared the acetone derivatives [*iso*propylidene ethers] of ethylene glycol, propane-αβ-diol, propane-αγ-diol, glycerol, and monochlorohydrin, 1 : 3-*ciscyclo*pentanediol, and 1 : 2-*ciscyclo*hexanediol. The method of preparation used was to heat suitable quantities of the glycol and acetone with sulphuric acid. The following new physical data are recorded: *iso*propylidene ether of ethyleneglycol, b. p. 92·5—92·7°, d_4^{17} 0·9469, n_D^{17} 1·40024, solubility in water, 1 vol. in 3½—4 vols. at 18°; *iso*propylidene ether of propane-αβ-diol, b. p. 98—99°, $n_D^{18\cdot5}$ 1·40191, $d_4^{18\cdot5}$ 0·9090, solubility in water, 1 vol. in 9—10 vols.; *iso*propylidene ether of propane-αγ-diol, b. p. 123—125°, $n_D^{18\cdot5}$ 1·4252, $d_4^{16\cdot5}$ 0·9587; *iso*propylidene ether of α-monochlorohydrin, b. p. 116°/11 mm., $d_4^{17\cdot5}$ 1·322, $n_D^{17\cdot5}$ 1·4820. The molecular weight of these compounds has been determined and is found to show no association of the molecules. The equilibrium constants of the reaction, acetone+

diol ⇌ *iso*propylidene ether + water, have been ascertained in each case, and the values compared with the difference in electrical conductivity of a 0·5 mol. solution of the diol containing 0·5 mol. of boric acid, and the sum of the electrical conductivities of a 0·5 mol. solution of boric acid and a 0·5 mol. solution of the diol. The two sets of figures are parallel, which is taken to indicate that the glycols combine with the same facility with acetone as they do with boric acid. A modification of the Le Bel–Henniger fractionating column was used in the purification of the materials, the bulbs of the original apparatus being connected with capillary tubes instead of the one opening; this causes the outside lateral tubes continuously to contain liquid. J. F. S.

The Condensation of Mannitol with Olive Oil. J. C. Irvine and H. S. Gilchrist (*J. Chem. Soc.*, 1924, **125**, 10—15).—" Mannitol fat " (cf. Lapworth and Pearson, A., 1919, i, 570), prepared by the interaction of mannitol and olive oil in the presence of sodium ethoxide, consists essentially of *mannitan dioleate*, which is formed by the dehydration of *mannitol dioleate*, the first product of the reaction. Further dehydration (at 200° under reduced pressure) results in the formation of iso*mannide dioleate*. Treatment of mannitan dioleate with excess of methyl iodide and silver oxide results only in the formation of *monomethylmannitan dioleate*, together with a trace of *monomethyl*iso*mannide* (n_D 1·4506), from *iso*mannide originally present. On boiling with 0·5% alcoholic hydrogen chloride, monomethylmannitan dioleate gives ethyl oleate and *monomethylmannitan*, a viscous syrup. The latter was methylated to *trimethylmannitan*, a clear, mobile syrup, b. p. 115—120°/0·18 mm., n_D 1·4518. Structural considerations based on the reactions described lead to the formula

$$\underbrace{CH_2\cdot CHOX\cdot CHOX\cdot CH}_{O}\cdot CHOH\cdot CH_2OH,$$

where X is the oleyl residue, for " mannitol fat." No more than two acyl groups can be introduced into the mannitol molecule. F. G. W.

The αγ-Dichloropropyl Ethers and the Corresponding Acetals. W. Dulière (*Bull. Soc. chim.*, 1923, **33**, [iv], 1647—1654; cf. Wohl, A., 1898, i, 555).—The ethers were prepared by saturating an equimolecular mixture of acraldehyde and aliphatic alcohol with dry hydrogen chloride at −10°, the products being purified by distillation under reduced pressure. They are colourless liquids of characteristic odour, decomposing with liberation of hydrogen chloride when heated at atmospheric pressure. They are not miscible with water, but react with it, hydrogen chloride being formed. With aliphatic alcohols, particularly those containing few carbon atoms, they readily produce acetals by reaction with the α-chlorine atom, and with magnesium alkyl halides monochloroethers are obtained. The following are described: *methyl αγ-dichloropropyl ether*, b. p. 45°/12 mm., d^{20} 1·187, n_D^{20} 1·44777, yielding, with methyl alcohol, the acetal *γ-chloro-αα-dimethoxy-*

propane, b. p. 45°/12 mm., d^{20} 1·059, n_D^{20} 1·41631; *ethyl* $\alpha\gamma$*-dichloropropyl ether* has b. p. 56°/12 mm., d^{20} 1·122, n^{20} 1·44235, and γ-chloro-α-diethoxypropane has d^{20} 0·991 (cf. Wohl, *loc. cit.*); *propyl* $\alpha\gamma$*-dichloropropyl ether*, b. p. 65°/12 mm., d^{20} 1·100, n_D^{20} 1·44576, and γ*-chloro-*$\alpha\alpha$*-dipropoxypropane* has b. p. 87°/20 mm., d^{20} 0·972, n_D^{20} 1·42871; $\alpha\gamma$*-dichloropropyl* iso*butyl ether*, b. p. 89°/21 mm., d^{20} 1·067, n_D^{20} 1·44305, and γ*-chloro-*α*-di*iso*butoxypropane*, b. p. 105°/12 mm., d^{20} 0·936; $\alpha\gamma$*-dipropyl* iso*amyl ether*, b. p. 103°/20 mm., d^{20} 1·027, turns brown and decomposes on being kept.

H. J. E.

The Alkyl Titanates. F. Bischoff and H. Adkins (*J. Amer. Chem. Soc.*, 1924, **46**, 256—259).—*Tetramethyl titanate*, prepared from methyl alcohol, sodium, and titanium tetrachloride, crystallising point 209—210°, b. p. 243°(corr.)/52 mm., is rapidly hydrolysed in air. *Tetraethyl titanate*, prepared similarly from ethyl alcohol, had b. p. 205°/156 mm., 145°/8·5 mm., d_{20}^{20} 1·107. *Tetra*iso*propyl titanate*, obtained mixed with 4% of *iso*propyl alcohol as a constant-boiling mixture, has b. p. 230°/740 mm. *Tetra-*n*-butyl titanate* has b. p. 185—187°/16 mm., d_{20}^{20} 0·993. On boiling the higher esters with methyl alcohol, a quantitative yield of the tetramethyl derivative is obtained. All these esters are colourless.

F. A. M.

Octyl Mercaptan. H. Kahn (*Bul. Soc. Chim. România*, 1923, **5**, 70—72).—Pure octane, obtained by the repeated fractionation of benzene from Ploesti and removal of aromatic hydrocarbons by repeated action of a mixture of nitric and sulphuric acids, is converted into octyl chloride, which, when treated with a saturated alcoholic solution of potassium hydrogen sulphide, yields *octyl mercaptan*, a colourless liquid of disagreeable odour, b. p. 198—200°. When heated, it readily decomposes into octyl sulphide and hydrogen sulphide.

J. W. B.

Valeric Acid. S. Koizumi and H. Ichinose (Japan. Pat. 41910).—Valeric acid is prepared from amyl alcohol by electrolytic oxidation in 5—20% sulphuric acid solution at the ordinary temperature. Lead or lead peroxide is used as anode, and platinum, copper, iron, or nickel as cathode, without diaphragm. The addition of 1 g. of oxides of vanadium, chromium, or manganese to 1 litre of the sulphuric acid promotes the reaction. The electrolyte is vigorously agitated during the operation, the current density being 1—5 amp. per sq. dm. The product separates in a nearly pure state, the current yield being above 80%.

K. K.

Palmitic and Stearic Anhydrides. D. Holde, J. Ripper, and F. Zadek (*Ber.*, 1924, **57**, [*B*], 103—104).—Since the constants recorded in the literature for these substances are very discordant, they have been redetermined with material prepared by Albitzky's method as modified by Holde and Tacke (A., 1920, i, 811). Palmitic anhydride has m. p. 64°, d_4^{83} 0·8383, whence d^{15} 0·8832, and n^{100} 1·4679. Stearic anhydride has m. p. 72°, d_4^{80} 0·855, whence d_4 0·897, and n_D^{100} 1·4284.

H. W.

The Composition and Constitution of Elæostearic Acid. L. MAQUENNE (*Bull. Soc. chim.*, 1923, **33**, [iv], 1654—1655).—The author claims priority over Vercruysse (A., 1923, i, 533) and refers to his own work (A., 1903, i, 62) in support of his view that the extreme readiness with which the acid undergoes oxidation has led to errors with regard to its formula and m. p., which are $C_{18}H_{30}O_2$ and 48°, respectively. H. J. E.

Elaidic Acid and its Anhydride. D. HOLDE and K. RIETZ (*Ber.*, 1924, **57**, [*B*], 99—102).—Elaidic acid, obtained by the action of nitrous acid on oleic acid, crystallises in colourless, lustrous leaflets, m. p. 44·4° (corr.), n_D^{100} 1·4308. Elaidic anhydride, prepared from the acid and acetic anhydride, has m. p. 46·4° (corr.), d_{15}^{82} 0·8476, d_{15}^{93} 0·8396, d_4^{100} 0·8338, n_D^{100} 1·4339.

The electrolytic conductivities of oleic and elaidic acids and their anhydrides in very highly purified acetone have been measured. Little differences are observed between the constants of the acids and their anhydrides, but those of elaidic acid and its anhydrides are somewhat higher than those of the oleic compounds. H. W.

The Relative Solubilities of the Calcium and Magnesium Salts of the Higher Fatty Acids. W. BILTZ and W. RÖHRS (*Z. angew. Chem.*, 1923, **36**, 609—611).—A study of the equilibria resulting from the action of solutions of calcium chloride on solid magnesium stearate and oleate. The mixture was heated for one hour, cooled, and filtered, the extent of double decomposition being found from analysis of the filtrate. When equimolecular proportions were used, the amounts of calcium stearate and oleate produced were 88% and 81%, respectively; these values increased to 98% and 90% on doubling the molecular ratio of calcium chloride. Fractional precipitation of a mixture of equivalent quantities of calcium and magnesium chlorides with potassium stearate and oleate yielded mainly calcium salt (Ca 6·54%, Mg 0·03%). Experiments on commercial soap are also described. The general conclusion is drawn that calcium stearate is considerably and calcium oleate appreciably less soluble than the corresponding magnesium salts. H. J. E.

The Composition of Whale Oil. C. H. MILLIGAN, C. A. KNUTH, and A. S. RICHARDSON (*J. Amer. Chem. Soc.*, 1924, **46**, 157—166).—Whale oil is shown to contain a complicated mixture of fatty acids having 14 to 22 carbon atoms, probably with a small amount of C_{24} acids. The highly unsaturated acids are chiefly those containing 20 and 22 carbon atoms. The percentage composition of the mixture of fatty acids is approximately: (C_{14}) myristic 4·5; (C_{16}) palmitic 11·5, palmitoleic 17·0; (C_{18}) stearic 2·5, unsaturated (nearly all oleic) 36·5; (C_{20}) unsaturated 16; (C_{22}) unsaturated 10; (C_{24}) unsaturated 1·5; unsaponifiable 0·7. F. A. M.

The Catalytic Hydrogenation of some Unsaturated Compounds, especially Oils, by Means of Nickel at the Ordinary Temperature. M. TANAKA (*Chem.-Ztg.*, 1924, **48**, 25—26).—The author has extended the work of Kelber (A., 1916, ii, 309, 609) by using nickel, precipitated on kieselguhr, for reduction at the ordinary temperature of ethyl cinnamate, cinnamaldehyde, cinnamyl alcohol, azoxybenzene (to azobenzene, hydrazobenzene, and aniline), ricinostearol di-iodide, perilla oil, hemp-seed oil, chrysalis oil, and shark oil. Details of the amounts of hydrogen fixed are given and also of similar experiments carried out with a palladium catalyst for comparison. [Cf. *B.*, Mar.] H. J. E.

Reaction of Zinc on Mixtures of Ethyl α-Bromo*iso*butyrate and Aldehydes or Ketones. I. Coucoulesco (*Bul. Soc. Chim. România*, 1923, **5**, 63—70).—The action of zinc on mixtures of ethyl α-bromo*iso*butyrate with *iso*valeraldehyde, *iso*propyl ketone, and acetophenone, respectively, has been studied. With *iso*valeraldehyde, the reaction takes the normal course and yields *ethyl* β-*hydroxy-*αα*δ-trimethylhexoate* (b. p. 173—175°/140—145 mm.), which is hydrolysed to β-*hydroxy-*αα*δ-trimethylhexoic acid*, colourless tetragonal or hexagonal crystals, m. p. 81°, α=0·00147. The acid is soluble in alcohol and in ether. The *barium*, *silver*, *potassium*, *zinc*, and *lead* salts are described. The action either of dilute sulphuric acid (1 : 10) or of hydrogen iodide on this acid yields the γ-*lactone*,

$CHMe_2{\cdot}\underbrace{CH{\cdot}CH_2{\cdot}CMe_2{\cdot}CO}_{O}$, b. p. 221—222°/742 mm., probably owing to the initial formation of the βγ-unsaturated acid. Oxidation of the acid with potassium permanganate yields only unchanged material, carbon dioxide, and water.

With the two ketones, the main products isolated are ethyl *iso*butyrate, unchanged ketones, and a small quantity of oil, which is probably the expected ester of the hydroxy-acid. This on hydrolysis yielded an acid oil from which a pure substance could not be isolated. J. W. B.

Synthesis of the Higher Monoalkylmalonic Acids. (Mrs.) G. M. Robinson (*J. Chem. Soc.*, 1924, **125**, 226—231).—A method for the preparation of higher monoalkylmalonic acids, suitable for use with considerable quantities of material in one operation, and in which the formation of the corresponding dialkyl acids is minimal, is as follows. A mixture of the higher alkyl iodide (1 mol.), ethyl cyanoacetate (2 mols. or more), and potassium carbonate (1·5 mols.) is boiled under a reflux condenser and at a reduced pressure until the reaction is completed. The unchanged cyanoacetate is then recovered by distillation, the whole residue hydrolysed with hot 20% sodium hydroxide, and the product precipitated with dilute sulphuric acid. Under these conditions, the hydrolysis of α-cyano*cyclo*hexylacetic acid yielded only the malonamic acid,

$CH_2{<}\begin{matrix}CH_2{\cdot}CH_2\\CH_2{\cdot}CH_2\end{matrix}{>}CH{\cdot}CH(CO{\cdot}NH_2){\cdot}CO_2H$, a result ascribed to steric hindrance. The remaining cyanoacetic acids examined were completely hydrolysed to the corresponding malonic acids. *cyclo-Hexylmalonamic acid*, colourless needles, m. p. 184°, was unattacked on heating for four hours with alcoholic potassium hydroxide.

Heated in a tube, it loses carbon dioxide and forms *cyclo*hexylacetamide.

The preparation of *n*-heptylmalonic acid, *n*-octylmalonic acid, rhombic prisms, m. p. 115°, n-*undecylmalonic acid*, rectangular needles, m. p. 108°, and *n*-hexadecylmalonic acid, m. p. 119°, is described in detail.

n-*Decyldimethylcarbinol*, obtained from methyl undecoate and magnesium methyl iodide, is a mobile liquid, b. p. 145°/10 mm.

F. G. W.

The Chlorosulphides of Carbon. Decomposition in Presence of Iron. M. DELÉPINE and J. GIRON (*Bull. Soc. chim.*, 1923, **33**, [iv], 1785—1792).—The chlorosulphides of carbon, when left in contact with metallic iron, are converted into sulphur and carbon tetrachloride. The action is catalytic, the iron suffering very little alteration. The chlorosulphides examined were: thiocarbonyl chloride, perchloromethyl mercaptan (also examined in presence of carbon disulphide and/or sulphur chloride), and the chlorosulphides represented by the formulæ: (1) $CCl_3{\cdot}S{\cdot}CS{\cdot}Cl$, (2) $CCl_3{\cdot}S_3{\cdot}CCl_3$, and (3) $C_2Cl_6S_4$ (obtained from the residue in the distillation of perchloromethyl mercaptan, and having b. p. 150—154°/26 mm.).

E. E. T.

Condensation of Citral with Ketones and Synthesis of some New Ionones. H. HIBBERT and L. T. CANNON (*J. Amer. Chem. Soc.*, 1924, **46**, 119—129).—Citral, purified by a modification of Tiemann's method (A., 1899, i, 622), was condensed with acetone by means of sodium ethoxide, giving a 55% yield of pure ψ-ionone. The best condensing agent for converting ψ-ionone into α-ionone was found to be 85% phosphoric acid. *ψ-Ethylionone*, prepared from citral and methyl propyl ketone, is a pale yellow oil, b. p. 155—158°/8 mm.; its structure is probably $Me_2C{:}CH{\cdot}CH_2{\cdot}CH_2{\cdot}CMe{:}CH{\cdot}CH{:}CH{\cdot}CO{\cdot}Pr$. It is converted by means of 85% phosphoric acid into *ethylionone*, a pale yellow oil, b. p. 138—140°/8 mm., possessing a pleasant odour of violets.

Citral condenses with acetophenone, in presence of sodium ethoxide, to form *phenyl-ψ-ionone*, an odourless, viscous, pale yellow oil, b. p. 182—185°/4 mm. *Phenylionone*, prepared from it by the action of 85% phosphoric acid, is a pale yellow, viscous oil, b. p. 172—175°/4·5 mm., with a very faint but rather disagreeable odour, the violet fragrance being almost entirely suppressed.

Attempts to condense citral with diethyl ketone or dipropyl ketone were unsuccessful.

F. A. M.

Ring-chain Tautomerism. IX. The Mutarotation of the Sugars. J. W. BAKER, C. K. INGOLD, and J. F. THORPE (*J. Chem. Soc.*, 1924, **125**, 268—291).—A proof, from a dynamical investigation and survey of structural evidence, supported by data from two series of crucial experiments, that the mutarotation of the sugars is a case of ring-chain tautomerism in the sense

$$[H]O{\cdot}(C)_n{\cdot}\overset{|}{C}{:}O \rightleftharpoons O{\cdot}(C)_n{\cdot}C{\cdot}O[H]$$

on lines suggested by Jacobson and Stelzner (Meyer and Jacobson's "Organischen Chemie," 2 Aufl., 1, **2**, 886, 910, 915, 927), and not dependent on the intermediate formation of hydrates as suggested by Lowry (T., 1903, **83**, 1316) and Armstrong (T., 1903, **83**, 1309). It is postulated that the phenomenon is of the same nature in all cases and not of varying kinds as suggested by Irvine and Steele (T., 1915, **107**, 1239—1240). The full mathematical derivation of the form and spacing of the mutarotation–time curves on the mutarotation–time–concentration diagram, according to the tautomeric-hydrogen theory, is given. It is deduced that whilst the form of the mutarotation–time curves can be accommodated by the intermediate-hydrate theory, the spacing of curves obtained from measurements of mutarotation in presence of varying initial concentrations of water is zero, in direct contradiction of the consequences of the hydrate theory, and in agreement with the experimental results. From structural considerations, it is pointed out that whilst *d*-fructose should not be capable of mutarotation according to Armstrong's theory, its mutarotation has actually been measured in water, pyridine, and formamide solutions, and that *d*-glucoseoxime, *d*-glucoseanilide, *d*-glucoseimine, *d*-glucosephenylhydrazone, and ethylamino-*d*-glucose, all show mutarotation contrary to expectations based on Lowry's views. Also, no substance which, according to all three theories, should be incapable of mutarotation, has been found to exhibit this phenomenon, although interconversion of isomeric forms can sometimes be effected by reagents. This is shown to be at variance with Armstrong's views, and it is suggested that the mechanism of such conversions is fundamentally different from that of mutarotation. Experimentally, the mutarotation of tetra-acetyl-*d*-glucose in ethyl acetate solution at 44·8° was measured under conditions such that water was rigorously excluded, or present in small, accurately known concentrations of 0·025, 0·05, and 0·1%, respectively, these amounts being small in proportion to that possibly present in the dried materials. The velocity constants were, respectively, 0·0222, 0·0221, 0·0209, and 0·0208, *i.e.*, independent of the small initial concentration of water. The mutarotation of α-*d*-glucose in methyl alcohol was also measured at the same temperature, first with dried materials, and then in presence of 0·5, 1·0, and 2·0%, respectively, of added water, these concentrations of water being relatively large in comparison with that which might have been present originally. The initial velocities were, respectively, 0·165, 0·178, 0·246, and 0·379. These values are not in proportion to the initial concentration of the water, as the hydrate theory demands. F. G. W.

Oxidation of Dextrose by Iodine in the Presence of Insulin. G. A. Alles and H. M. Winegarden (*J. Biol. Chem.*, 1923, **58**, 225—234).—The rate of oxidation of dextrose by iodine is not altered by the presence either of insulin alone or of insulin plus liver extract, blood-serum, or oxalated blood. Since the rates of oxidation of the various sugars differ greatly, it is evident that, under the conditions employed, insulin does not transform dextrose into a more reactive form (cf. Winter and Smith, A., 1923, i, 513). E. S.

A Quantitative Study of the Interaction of Dextrose and Phenylhydrazine. E. Knecht and F. P. Thompson (*J. Chem. Soc.*, 1924, **125**, 222—226).—In view of the strong reducing properties of phenylhydrazine and its resistance to reduction by titanous chloride, the reaction between phenylhydrazine and dextrose was studied to confirm quantitatively the formation of aniline and ammonia simultaneously with the osazone, and to discover the fate of the reactants in view of the low yields of osazone usually obtained. Pure dextrose (1 mol. : 3·6 g.) and phenylhydrazine (3 mols. : 6·48 g.) were dissolved in a mixture of water (190 c.c.) and glacial acetic acid (10 c.c.) and heated for three hours on the water-bath. A parallel experiment was made using *p*-nitrophenylhydrazine, but at twice the dilution of dextrose and phenylhydrazine. The osazone was filtered off and weighed. The unchanged phenylhydrazine was determined by boiling with Fehling's solution and measuring the nitrogen evolved, and the ammonia by a distillation during which tarring was avoided. The amount of ammonia produced in both cases was in agreement with that calculated from the weight of osazone obtained, in accordance with Fischer's equation, but it is inferred that a portion of the dextrose remains in solution as phenylhydrazone. The addition of aniline acetate or ammonium acetate to the reaction mixture increases the yield of osazone. By heating 3·6 g. of dextrose and 6·48 g. of phenylhydrazine with 20 c.c. of glacial acetic acid diluted to 100 c.c. with water, for three hours at water-bath temperature, a yield of osazone corresponding with 84% of the theoretical may be obtained. F. G. W.

A Synthetic Fat containing a Methylglucoside Residue. J. C. Irvine and H. S. Gilchrist (*J. Chem. Soc.*, 1924, **125**, 1—10).—When olive oil (1 mol.) is heated with α-methylglucoside (3 mols.) in presence of sodium ethoxide at 140°, *methylglucoside mono-oleate* is formed, and this on further heating at 220°/12 mm. loses water and forms *anhydro-methylglucoside mono-oleate*, a viscous, yellow oil, $[\alpha]_D^{15} + 38°$ in chloroform. Attempts to introduce more than one oleyl residue failed. Treatment of the anhydro-mono-oleate with methyl iodide and silver oxide gave *monomethyl-anhydro-methylglucoside mono-oleate*, a mobile, yellow oil; this on boiling with methyl-alcoholic hydrogen chloride gave methyl oleate and *monomethyl-anhydro-methylglucoside*, a colourless, viscous syrup. The latter was further methylated to *dimethyl-anhydro-methylglucoside*, b. p. 115—120°/0·2 mm., n_D 1·4419, and hydrolysed with barium hydroxide to *monomethyl methylglucoside*, a colourless, viscous syrup. Further hydrolysis with 5% hydrochloric acid at 100° gave a syrupy monomethylglucose. Consideration of the reactions described leads to the formula,

$$\underbrace{CHOMe\cdot CHOH\cdot CHOX\cdot CH}_{O}\cdot \underbrace{CH\cdot CH_2}_{O},$$

where $X{=}CO\cdot[CH_2]_7\cdot CH{:}CH\cdot[CH_2]_7\cdot CH_3$, for the methylglucoside fat. F. G. W.

Fluoroacetyl Derivatives of Sugars. II. Optical Rotation and Atomic Dimension. D. H. BRAUNS (*J. Amer. Chem. Soc.*, 1923, **45**, 2381—2390).—In comparing the optical rotations of monohalogen-acetyl derivatives of dextrose, cellose, xylose, and lævulose, the differences F–Cl, Cl–Br, Br–I are found to be approximately proportional to the differences in atomic diameter. This simple relation holds for the specific, but not for the molecular rotation. *Fluorotetra-acetyl-lævulose* is obtained from β-penta-acetyl-lævulose. It is readily soluble in chloroform, and has m. p. 112°, $[\alpha]_D^{20}$ −90·43° in chloroform. It is stable, colourless, and odourless. *Bromotetra-acetyl-lævulose* was prepared by the action of a solution of hydrogen bromide in glacial acetic acid on a solution of β-penta-acetyl-lævulose in the same solvent. It is a very unstable, crystalline solid, $[\alpha]_D^{20}$ −189·1° in chloroform, m. p. 65°. When preserved, it is transformed into β-tetra-acetyl-lævulose. F. G. P.

Unsaturated Reduction Products of the Sugars and their Transformations. VIII. M. BERGMANN [and, in part, H. SCHOTTE, E. RENNERT, S. LUDEWIG, and M. KOBEL] (*Annalen*, 1923, **434**, 79—110).—Fischer and Curme (A., 1914, i, 931) obtained a substance, which they described as lactal, by the hydrolysis of hexa-acetyl-lactal by means of barium hydroxide. This product had 1 mol. of water of crystallisation, $[\alpha]_D$ +26·77° to +26·95°, m. p. 184—186°, or, when anhydrous, m. p. 165—170°. Lactal prepared by using methyl-alcoholic ammonia instead of barium hydroxide is anhydrous, and has $[\alpha]_D^{16}$ +27·66° to +27·67°, m. p. 192° (corr.), decomp. about 212°. A sample so prepared is not changed on standing with barium hydroxide solution at 37° for two or three days. Lactal prepared by means of ammonia is reconverted by the action of acetic anhydride and pyridine into the hexa-acetate, m. p. 114°, but the product from "baryta-lactal" has m. p. 108—109°. It is thought that Fischer and Curme's material was simply impure lactal.

When lactal is boiled with water, the product has m. p. 198° (corr.), $[\alpha]_D^{17}$ +36·43°, but the other properties are, in general, unchanged.

Hexa-acetyl-lactal is converted by boiling with water into *ψ-lactal penta-acetate*, a heavy, snow-white powder (flat tablets, small, thin prisms, or elongated, hexagonal crystals), m. p. 123—124° (corr.) after previously softening, decomp. 190°. The structure of this compound is different from that of lactal or its hexa-acetate, because on treatment with acetic anhydride and pyridine it gives *ψ-lactal hexa-acetate*, aggregated prisms or needles, m. p. 127—128° (corr.), $[\alpha]_D^{18}$ +32·24°, which is reconverted, by boiling with water, into the penta-acetate. Both the penta- and the hexa-acetate of ψ-lactal have a bitter taste; the hexa-acetate does not give the pine-shaving reaction, and does not react with bromine, but it reduces ammoniacal silver nitrate solution, and gradually gives a red coloration with magenta–sulphurous acid. In its sensitiveness to even dilute mineral acids it resembles lactal and the deoxy-sugars.

When ψ-lactal penta-acetate is treated successively with cold methyl-alcoholic hydrogen chloride, sodium hydroxide solution (with cooling), and sodium hydroxide and methyl sulphate, a yellow syrup is obtained, b. p. 178—180°/0·3—0·4 mm., $n_D^{50·5}$ 1·4661; this is the *pentamethyl* ether of a *compound*, $C_{12}H_{20}O_9$, isomeric with lactal. This series of reactions may involve a change of structure. When ψ-lactal penta-acetate is treated at 0° with a saturated solution of hydrogen bromide in glacial acetic acid, two molecular proportions of hydrogen bromide are taken up, giving a *dibromide*, $C_{22}H_{30}O_{13}Br_2$, small prisms or needles, m. p. 124° (corr.) (decomp.), $[\alpha]_D^{23}$ +69·6°. The latter is converted by means of silver carbonate in moist acetone solution into a *hydroxybromide*, $C_{22}H_{30}O_{13}Br(OH),\frac{1}{2}H_2O$, snow-white, glistening flakes, m. p. 87—88° after sintering at 80°, decomp. 110°. In dry methyl-alcoholic solution, the product is the corresponding *methoxybromide*, m. p. 147—148° (corr.), with subsequent decomposition, which is hydrolysed by means of methyl-alcoholic ammonia to the free *bromomethoxy*-derivative, snow-white, aggregated needles, m. p. 119° (decomp.). ψ-Lactal penta-acetate, which need not be isolated, is converted by the action of cold barium hydroxide solution into iso*lactal*, short, slender needles, which is very difficult to purify. It has a vigorous reducing action on Fehling's solution, and gives a green coloration with a pine shaving. With warm alkali, it becomes yellow or brown, whilst concentrated mineral acids give a red solution; it is not attacked by perbenzoic acid. *iso*Lactal has a slightly sweet taste, resembling that of lactose. The action of acetic anhydride and pyridine on *iso*lactal gives iso*lactal hexa-acetate*, rhombic prisms, or leaflets, m. p. 166—167° after sintering at 163°, $[\alpha]_D^{23}$ +55·30°, which gives the pine-shaving test, and has an insipid taste. By the action of boiling water, one acetyl group is eliminated. *iso*Lactal may be acetalised by means of methyl-alcoholic hydrogen chloride, or methylated by means of methyl sulphate; it is rapidly oxidised by means of aqueous bromine.

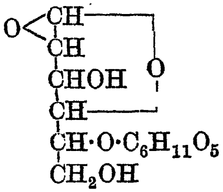
The action of perbenzoic acid, in warm ethyl acetate solution, on an aqueous solution of lactal gives 5-*galactosidomannose*, needles, m. p. 196—197° (corr.), after slight softening. This compound has, initially, $[\alpha]_D^{23}$ +23° (about), rising to +30° after eighty minutes. It reduces Fehling's solution immediately, and reacts gradually with ammoniacal silver nitrate solution or magenta and sulphurous acid. With phenylhydrazine, it gives lactosazone; it is decomposed by emulsin.

The diacetate, obtained by boiling triacetylglucal with water, is converted by heating with acetic anhydride and sodium acetate at 100° into *ψ-glucal triacetate*, a colourless liquid, b. p. 150—165°/0·2—0·3 mm., which has a bitter taste and a pungent odour. It is reconverted by the action of boiling water into the diacetate, which is described as ψ-glucal diacetate. The triacetate is highly sensitive to the action of acids, and immediately becomes brownish-black when treated with cold alkali. It gives an intensely green coloration with a pine shaving, and reacts with magenta–sulphurous acid, Fehling's solution, or ammoniacal silver nitrate. With bromine in chloroform solution at 18°, two atoms of halogen are absorbed, one of which may then be removed by boiling with silver carbonate and dry methyl alcohol. The action of 1% methyl-alcoholic hydrogen chloride on ψ-glucal diacetate gives a pale yellow syrup, from which the following fractions are isolated. (1) A colourless, mobile liquid, b. p. 68—69°/0·3 mm., n_D^{20} 1·4763, $[\alpha]_D^{22}$ +1·2°, apparently $C_7H_{10}O_3$, and perhaps the methyl*cyclo*-acetal of a hydroxyaldehyde, with two bonds, and a methylene group adjacent to the acetalised aldehyde group. (2) A viscous, slightly yellow oil, b. p. 88—90°/0·1 mm., n_D^{20} 1·4984, $[\alpha]_D^{20}$ +15·50—+16·1°, evidently $C_8H_{12}O_4$. (3) A viscous, colourless liquid, apparently $C_7H_{12}O_4$, b. p. 120—121°/0·2 mm., n_D^{20} 1·4860, $[\alpha]_D^{20}$ +71·7—+72·2°. Each of these fractions gives a green pine-shaving reaction, and is sensitive to acids; Fehling's solution is not reduced. The action of cold barium hydroxide solution on ψ-glucal diacetate gives iso*glucal*, a syrup, b. p. 120—130°/0·2—0·3 mm. (but sublimes at about 60° at this pressure), $[\alpha]_D^{23}$ +43·15°, which is isolated as its *phenylbenzylhydrazone*, microscopic needles, m. p. 121—122°, $[\alpha]_D^{22}$ −22·38°, from which it is regenerated by boiling with aqueous benzaldehyde or concentrated formaldehyde solution, the former being preferable. *iso*Glucal is readily decomposed by means of acids or of alkali. It gives a very pronounced green coloration with a pine shaving, and vigorously reduces Fehling's solution. On keeping the syrupy material in a vacuum, *crystals* are gradually deposited, m. p. 49—50°, $[\alpha]_D^{18}$ +45·6°, which, in contrast with the original material, do not give a coloration with magenta–sulphurous acid. The syrupy *iso*glucal rapidly reacts with bromine, but in chloroform solution the reaction is apparently incomplete. Neutral or alkaline permanganate solution is immediately decolorised, but perbenzoic acid is not attacked.

Acetobromomaltose is reduced by means of zinc dust and 50% acetic acid, giving a poor yield (50%) of impure acetomaltal. The latter, when boiled with water, gives *penta-acetylmaltal hydrate*, needles, m. p. 173—174° (corr.); when acetylated, it gives a *hexa-acetate*, m. p. 155—157°. The elimination of the acetyl groups from acetomaltal, followed by oxidation using perbenzoic acid, gives a disaccharide containing mannose, perhaps 6-glucosidomannose (details will be given later).

When a solution of rhamnal in *N*-sulphuric acid is continuously extracted with ether at 35°, a yellow liquid is removed; the aqueous solution then contains l-*rhamnodeose* (2-*deoxy*-l-*rhamnose*), a colourless liquid. This substance is very readily decomposed by the action of mineral acids. It gives the pine-shaving reaction, and reduces Fehling's solution. It is converted by keeping at 20° with methyl-alcoholic hydrogen chloride into its *methyl*cyclo*acetal*, b. p. 120—130°/0·2 mm., which undergoes fission when boiled with aqueous hydrochloric acid. When rhamnodeose is oxidised by means of aqueous bromine solution, the product is *rhamnodesonic* *acid*, which is isolated as its *barium* salt, colourless needles, or as the *phenylhydrazide*, m. p. 172—172·5° (corr.). Kiliani's digitoxose is therefore not identical with *l*-rhamnodeose.

It is proposed (cf. Bergmann, Schotte, and Lechinsky, A., 1922, i, 227) that, in naming a reducing disaccharide, the name of the sugar containing the intact aldehydic group should end in "ose," whilst the second constituent should be named as a glucosidic substituent, *e.g.*, 5-galactosidomannose. If both the reducing groups are glucosidically bound, as in trehalose, a name such as glucosidoglucoside is advocated. Thus sucrose becomes glucosidofructoside, or, alternatively, fructosidoglucoside, but raffinose is called galactosido-(glucosidofructoside). The terms anhydro-sugar, anhydrobiose, etc., are only employed when the aldehyde group, or its half-acetal form, is not involved in the anhydrisation; otherwise, one speaks of monose-anhydride, disaccharide-anhydride, etc. The points of attachment of the oxygen bridge are indicated by means of bracketed numbers. Thus the substance having the annexed formula is designated 5-galactosidomannose-anhydride [1 : 4] [1 : 2]. W. S. N.



The Action of Iodine on Several Carbohydrates. J. Vintilescu and D. Faltis (*Bul. Soc. Chim. România*, 1923, **5**, 59—63).—When powdered iodine is heated (in a steam bath) in a sealed tube with solutions of sucrose, invert-sugar, dextrose, lævulose, lactose, dextrin, glycogen, or gum arabic, the iodine passes slowly into solution during the first period of heating, and is completely converted into hydriodic acid, the solution becoming colourless. On prolonged heating, decomposition of the carbohydrate occurs, with the formation of formaldehyde, formic acid, and a brown oxidation product of the sugar. The iodine is transformed more easily by sugars containing lævulose and progressively slowly by dextrose, lactose, dextrin, glycogen, and gum arabic; the period of heating necessary to cause the same amount of final decomposition follows the same order. The reaction is more rapid the greater the concentration of the sugar solution. The action of hydriodic acid on the carbohydrates is found to be similar, but the destruction of reducing sugars formed is slower than is the case when iodine is added directly. [Cf. *B.*, 1924, 190.] J. W. B.

Wood Cellulose. E. Heuser and S. S. Aiyar (*Z. angew. Chem.*, 1924, **37**, 27—28).—The hypothesis of the identity of cellulose obtained from different sources is supported by experiments with cotton cellulose and wood cellulose. Both specimens give the same yield of pure cellulose triacetate on acetylation with glacial acetic acid, acetic anhydride, and sulphuryl chloride (cf. Barnett, A., 1921, i, 164), and on further treatment with methyl alcohol and hydrogen chloride (cf. Irvine and others, T., 1920, **117**, 1489; 1922, **121**, 1585) both triacetates give the same yield of the same α-methylglucoside. Hydrolysis of both samples of cellulose with 72%

sulphuric acid (cf. Ost and Wilkening, A., 1910, i, 364) and recovery of the dextrose (cf. Monier-Williams, T., 1921, **119**, 803) gives the same yield of crystalline dextrose. W. T. K. B.

The Constitution of Polysaccharides. VII. Esparto Cellulose. J. C. IRVINE and E. L. HIRST (*J. Chem. Soc.*, 1924, **125**, 15—25).—The amount of furfuraldehyde produced by the action of hydrochloric acid on esparto cellulose corresponds with the presence of 18·5% of pentosan in the dry, bleached material. This pentosan can be completely extracted with boiling 12% sodium hydroxide, and was identified as xylan by hydrolysis, in 2% sulphuric acid at 90°, to xylose. The total yield of xylose, based on optical measurements, was 75%, and the nett yield of crystalline material 35—50%, m. p. 143—144°. The latter yielded on methylation the same trimethyl β-methylxyloside as has previously been obtained from xylose. The formation of furfuraldehyde during the hydrolysis of the xylan could not be prevented. The remaining 81·5% of the esparto cellulose, after complete extraction of the pentosan with alkali, gave on acetylation cellobiose octaacetate, and on methylation a trimethyl derivative from which 2 : 3 : 6-trimethylglucose was obtained on hydrolysis, thereby establishing the identity of the alkali-extracted material with cotton cellulose. The original esparto cellulose is more resistant to acetylation than cotton cellulose; the acetate was prepared by incorporating the material with glacial acetic acid containing a little chlorine, adding acetic anhydride, and then passing in a little sulphur dioxide and stirring, when a clear solution was obtained after twenty-four hours. The yield of acetate corresponds with 97·2% of the theoretical, assuming that the pentosan forms a diacetate and the remainder a triacetate. The acetate is softer and more sensitive to high temperature than that of cotton cellulose. On treatment with 1·5% methyl-alcoholic hydrogen chloride at 130° for 120 hours, the acetate yields a mixture of α- and β-methylglucoside and α- and β-methylxyloside, from which pure α-methylglucoside was isolated by crystallisation from alcohol. It is concluded that esparto cellulose is a mixture of 81·5% of hexose cellulose and 18·5% of pentosan, probably in the form of a solid solution. F. G. W.

Starch Iodide. A. LOTTERMOSER (*Oesterr. Chem. Ztg.*, 1924, **27**, 13; cf. A., 1922, i, 10).—Experiments are mentioned on the adsorption of tri-iodion, iodion, and iodine by starch. The curves obtained are typical adsorption isotherms. In the reaction between starch and iodine in the presence of potassium iodide, there is probably an initial adsorption followed by a further slow combination. G. W. R.

Lignosulphonic Acid and the Lactone of Waste Sulphite Liquors. S. V. HINTIKKA (*Cellulosechemie*, 1923, **4**, 93—94).—Salts of α-lignosulphonic acid with primary amines were prepared by separating the sodium lignosulphonate by salting out from waste sulphite liquors and precipitating the aqueous solution of the product with α-naphthylamine sulphate, β-naphthylamine hydrochloride, and *o*-toluidine salt. Klason (A., 1922, i, 324) has considered the α-naphthylamine compound to be a normal ammonium salt of the sulphonic acid, and the β-naphthylamine compound a cyclic internal salt coupling the sulphonic acid and the aldehyde groups. The behaviour of these compounds towards 5% sodium hydroxide at 50° has been studied, the liberated amine being removed by extraction with ether and the lignosulphonic acid reprecipitated by acidification. No difference in the behaviour of these amine salts could be detected; the regenerated lignosulphonic acids were similar in appearance and contained only small residues of nitrogen. The crystalline substance isolated by Holmberg (A., 1921, i, 849) from waste sulphite liquors and described as a lactone has been further investigated. It occurs in the liquors from the digestion of spruce wood, but could not be detected in those from pine wood or from spruce bark. In the digestion of spruce wood, this lactone can be isolated in substantial quantity from the liquor in the early stages of digestion, but the quantity decreases towards the end of the process. J. F. B.

Preparation of Methylamine. M. SOMMELET (*Compt. rend.*, 1924, **178**, 217—219).—Methylamine hydrochloride, prepared by the methods of Brochet and Cambier or of Werner (cf. T., 1917, **111**, 844), is found to contain ammonium chloride and trimethyltrimethylenetriamine hydrochloride. It may be obtained pure by rendering alkaline, extracting with benzaldehyde, distilling the resulting benzylidenemethylamine (b. p. 180°), hydrolysing the latter with hydrochloric acid, washing the methylamine hydrochloride so obtained with alcohol to remove traces of the triamine salt, and finally crystallising twice from 88% alcohol. Pure methylamine hydrochloride has m. p. (in closed tube) 232—233·5° (corr.). E. E. T.

Tetrachloro-iodides of Organic Bases. F. D. CHATTAWAY and F. L. GARTON (*J. Chem. Soc.*, 1924, **125**, 183—188).—Stable tetrachloro-iodides of most organic bases can be prepared by dissolving the base in strong hydrochloric acid, adding an equivalent quantity of iodine, and passing excess of chlorine into the solution. The iodine gradually dissolves with evolution of heat and the tetrachloro-iodide separates either immediately or on allowing the solution to cool in a current of chlorine. The yields are generally quantitative. The tetrachloro-iodides are all golden-yellow, crystalline compounds, soluble in water with slight decomposition. They may be recrystallised from suitable solvents, to which the addition of a little iodine trichloride is sometimes necessary to prevent dissociation. They have sharp melting points, at which decomposition generally takes place, but appear to soften about 20° below the melting point. Heated at higher temperatures, they evolve chlorine, iodine monochloride, and iodine, and leave a residue of the chloride of the base. They can be stored unchanged for at least a month in dry air or in a vacuum over lime. The iodine atom appears to act as the central atom of the negative ion, the four chlorine atoms being arranged tetrahedrally around it, the general formula thus becoming similar to that usually assigned to the chloroaurates. *Guanidine tetrachloro-iodide*, $NH:C(NH_2)\cdot NH_3ICl_4$, golden-yellow, flattened prisms, m. p. 163°. *Carbamide tetrachloro-iodide*, $NH_2\cdot CO\cdot NH_3\cdot ICl_4,H_2O$, long, pale yellow needles, m. p. 73°. The tetrachloro-iodides of pyridine, quinoline, etc., are so sparingly soluble that for their preparation it is necessary to dissolve the iodine in hydrochloric acid by means of a current of chlorine before adding the base. *Pyridinium tetrachloro-iodide*, pale yellow, flattened prisms, m. p. 205° (decomp.). *α-Picolinium tetrachloro-iodide*, bright yellow, flattened prisms showing multiple twinning, m. p. 166° (decomp.). *Collidinium tetrachloro-iodide*, $C_5H_2Me_3N,HICl_4$, orange-yellow, long, flat, rhombic prisms, m. p. 94°. *Quinolinium tetrachloro-iodide*, $C_9H_7N,HICl_4$, pale yellow prisms, m. p. 195° (decomp.). 8-*Methylquinolinium tetrachloro-iodide*, $C_9H_6MeN,HICl_4$, long, pale yellow, hair-like crystals, m. p. 152° (decomp.). 6-*Nitroquinolinium tetrachloro-iodide*, $NO_2\cdot C_9H_6N,HICl_4$, dull yellow, elongated plates, m. p. 131° (decomp.). 2-*Chloroquinolinium tetrachloro-iodide*, $C_9H_6ClN,HICl_4$, pale yellow, flattened prisms, m. p. 143° (decomp.). 6-*Chloroquinolinium tetrachloro-iodide*, dull yellow, crystalline powder, m. p. 131° (decomp.). *Quinaldinium tetrachloro-iodide*, $C_9H_6MeN,HICl_4$, dull yellow, dendriform crystals, m. p. 149° (decomp.). *Caffeine tetrachloro-iodide*, $C_8H_{12}O_2N_4,HICl_4$, pale yellow, crystalline powder, m. p. 134° (decomp.). *Piperidinium tetrachloro-iodide*, $C_5H_{10}NH,HICl_4$, exists in two polymorphic forms; it crystallises from acetic acid in canary-yellow, fern-like crystals, which change on standing in contact with the mother-liquor into compact, six-sided, orange-yellow prisms. Both forms melt at 102° (decomp.). *Piperazine* bis-*tetrachloro-iodide*, $HICl_4,C_4H_{10}N_2,HICl_4$, bright yellow, compact prisms with domed ends, darkens on heating above 100°, and loses iodine trichloride at 160°; iodine is liberated at 195°, a black charred residue remaining. *Pyridine-betaine tetrachloro-iodide*, $C_5H_5N(ICl_4)\cdot CH_2\cdot CO_2H$, bright yellow, compact, six-sided prisms, m. p. 133° (decomp.). Semicarbazide does not form a tetrachloro-iodide, but is decomposed by a solution of $HICl_4$ into nitrogen, carbon dioxide, and ammonium tetrachloro-iodide. *Methylammonium tetrachloro-iodide*, $CH_3\cdot NH_2,HICl_4$, long, golden-yellow, hexagonal prisms with domed ends, m. p. 96° (decomp.). *Dimethylammonium tetrachloro-iodide*, $(CH_3)_2NH,HICl_4$, compact, orange-yellow prisms, m. p. 82° (decomp.). *Trimethylammonium tetrachloro-iodide*, canary-yellow plates, m. p. 182° (decomp.). *Ethylammonium tetrachloro-iodide*, $C_2H_5\cdot NH_2,HICl_4$, hygroscopic, orange-yellow, compact rhombs, m. p. 45°. *Diethylammonium tetrachloro-iodide*, thin, four-sided, pale yellow plates, m. p. 79° (decomp.). *Ethylenediammonium* bis-*tetrachloro-iodide*, $\left.\begin{matrix}CH_2\cdot NH_2,HICl_4\\ CH_2\cdot NH_2,HICl_4\end{matrix}\right\}2H_2O$, golden-yellow, long, hexagonal prisms,

m. p. 105° (decomp.). *Benzylammonium tetrachloro-iodide*, $C_6H_5{\cdot}CH_2{\cdot}NH_2,HICl_4$, flattened, yellow prisms, m. p. 97° (decomp.). *Dibenzylammonium tetrachloro-iodide*, $(C_6H_5{\cdot}CH_2)_2NH,HICl_4$, fine, yellow needles, m. p. 165°. *Tribenzylammonium tetrachloro-iodide*, $(C_6H_5{\cdot}CH_2)_3N,HICl_4$, yellow rhombs, m. p. 100° (decomp.).
F. G. W.

The Constitution of Galegine. G. Barger and F. D. White (*Biochem. J.*, 1923, **17**, 827—835).—The unsaturated amine, $C_5H_{11}N$, first obtained by Tanret by hydrolysis of galegine from the seeds of *Galega officinalis* (A., 1914, i, 721), gives Hofmann's carbylamine reaction, forms a toluenesulphonamide soluble in sodium hydroxide, and decolorises acid potassium permanganate. It has d_{18}^{18} 0·779, and forms a *chloroplatinate*, m. p. 194—197°, a *chloroaurate*, m. p. 81°, and a *picrate*, m. p. 138·5—139·5°. It is identified as an aminoamylene. The urea obtained by Tanret from galegine arises from a guanidine residue. Galegine sulphate gives Weyl's reaction and the diacetyl reaction, and in the presence of a palladium catalyst takes up 1 mol. of hydrogen to give *dihydrogalegine sulphate*, $(C_6H_{15}N_3)_2,H_2SO_4$, colourless prisms, m. p. 270°. The *nitrate*, long needles, m. p. 75—76°, and the *picrate*, long, narrow plates, m. p. 172°, are also described. On distilling the sulphate with quicklime *iso*amylamine was obtained. Dihydrogalegine (*iso*amylguanidine) synthesised from cyanamide and *iso*amylamine gave the same salts as the product obtained by reduction of galegine from natural sources. The oxidation of galegine sulphate with barium permanganate yielded acetone and glycocyamine. On being boiled with dilute sulphuric acid, galegine takes up 1 mol. of water to form *hydroxydihydrogalegine sulphate*, $(C_6H_{15}ON_3)_2,H_2SO_4$, m. p. 205—206°, which yields on hydrolysis hydroxy*iso*amylamine. *Hydroxydihydrogalegine picrate*, rhomb-shaped crystals, has m. p. 153—154°. On the basis of these results, the formula $Me_2C{:}CH{\cdot}CH_2{\cdot}NH{\cdot}C({:}NH){\cdot}NH_2$ or

$$CH_2{:}CMe{\cdot}CH_2{\cdot}CH_2{\cdot}NH{\cdot}C({:}NH){\cdot}NH_2$$

is ascribed to galegine. The cyclic structures suggested by Tanret (*loc. cit.*) are therefore both incorrect. J. P.

The Absorption Spectra of some Amino-acids. The Possible Ring Structure of Cystine. F. W. Ward (*Biochem. J.*, 1923, **17**, 898—902).—Phenylalanine, tryptophane, and tyrosine show marked absorption bands, whereas alanine, histidine, glutamic acid, and cystine give general absorption. Cystine is the only amino-acid having any marked absorption in the region of the solar ultra-violet, and it shows absorption of greater intensity than that of the other aliphatic amino-acids examined, this being as strong as that of phenylalanine. A possible cyclic structure for cystine is suggested. J. P.

The Reaction between Nitriles and Organo-magnesium Compounds. Ethyl Cyanoacetate. R. Breckpot (*Bull. Soc. chim. Belg.*, 1923, **32**, 386—397).—The yield of ketone obtained from the reaction product of nitriles and the Grignard reagent is practically nil in the case of acetonitrile and phenylacetonitrile. Bruylants (A., 1923, i, 310) postulates the existence of an equilibrium between the tautomeric forms of a nitrile $\colon CH\cdot CN \rightleftharpoons \colon C\colon C\colon NH$, the normal form yielding a ketone by the Blaise reaction, the pseudo-acid form, on the other hand, yielding only condensation products. The formation of the condensation products is the result of the intermediate production of the derivative $\colon C\colon C\colon NMgBr$. With ethyl cyanoacetate and ethyl magnesium bromide, a violent reaction takes place; a certain amount of the ketone is obtained, but the main portion of the reaction mixture consists of tarry products, whilst considerable quantities of gas (ethylene) are evolved. Using four molecular proportions of the Grignard reagent to one of ester, the amount of ethylene obtained shows that the ester contains two labile hydrogen atoms which are almost completely eliminated by the Grignard reagent. If the operation is carried out by adding the Grignard reagent to the nitrile, much ethylene is liberated until slightly more than one gram-molecular proportion has been added, when the reaction stops abruptly, owing to the formation of $CN\cdot CH(MgBr)\cdot CO_2Et$. Addition of water to this compound regenerates the nitrile. The *ketimine* of ethyl propionylacetate, $CH_3\cdot CH_2\cdot C(\colon NH)\cdot CH_2\cdot CO_2Et$, b. p. 100—103°/12 mm., is a colourless liquid of musty odour, d_4^{20} 1·0169, n_D^{20} 1·4938. F. G. P.

The Relation between the Structure of Organic Halides and the Speed of their Reaction with Inorganic Iodides. I. The Problem of Alternating Polarity in Chain Compounds. J. B. Conant and W. R. Kerner (*J. Amer. Chem. Soc.*, 1924, **46**, 232—252).—A method has been developed for comparing the reactivities of the halogen atoms in organic compounds, consisting in measuring the rate of reaction between the organic halide and potassium iodide in acetone solution. The reactivity of the chlorine atom in three series of compounds of the type $A(CH_2)_nCl$ has been measured and compared with the reactivity of the chlorine atom in *n*-butyl chloride. The halogen atom is more reactive in the compounds $A\cdot CH_2Cl$ than in ACl or $A\cdot CH_2\cdot CH_2Cl$ in the three series studied, in which A is either benzoyl, phenyl, or carbethoxy. The influence of the group on the chlorine atom in the compounds of the type $A\cdot CH_2Cl$ is roughly proportional to the effect of the same group on the activity of the hydrogen atom in the compounds of the type $A\cdot CH_3$. In the benzoyl series, the compound $A\cdot CH_2\cdot CH_2Cl$ is eighty times more reactive than a simple normal alkyl chloride; in the phenyl and carbethoxy series, the activity of the corresponding compound is of the same order as that of the alkyl chlorides. The compounds $A\cdot CH_2\cdot CH_2\cdot CH_2Cl$ in the benzoyl and phenyl series are more reactive than the compounds $A\cdot CH_2\cdot CH_2Cl$, this increase being large in the benzoyl series; in the carbethoxy series no such increase is apparent. The chlorine atom in the next higher homologue in the phenyl and carbethoxy series is only as reactive as that in butyl chloride; no higher homologues were available in the benzoyl series. Phenylamyl, phenylhexyl, and phenylheptyl chlorides do not differ significantly in their reactivity from one another or from *n*-butyl or *n*-amyl chlorides.

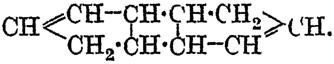
The preparation and properties of the following compounds are described: β-chloropropiophenone, from β-chloropropionyl chloride and benzene in presence of aluminium chloride, m. p. 49—50° (previous investigators have given it as 57—58°). *γ-Chlorobutyrophenone*, m. p. 19—20°. β-Phenylethyl chloride, from the corresponding alcohol and fuming hydrochloric acid at 140° for four to five hours, b. p. 68·5—69°/4 mm. *Phenylpropyl chloride*, from phenylpropyl alcohol and concentrated hydrochloric acid at 100°, b. p. 85—87°/9 mm. *δ-Phenylbutyl chloride*, b. p. 100—101°/6 mm. *ε-Phenylamyl chloride*, b. p. 111—112°/6 mm. *ζ-Phenylhexyl chloride*, b. p. 115—116°/4 mm. *Phenylheptyl chloride* was obtained only about 88% pure, from the crude alcohol and hydrochloric acid, b. p. 120—140°/3 mm. F. A. M.

Absorption of Ultra-violet Light by Organic Compounds. II. L. Marchlewski and A. Moroz (*Bull. Soc. chim.*, 1924, [iv], **35**, 37—40).—The results of studying the ultra-violet absorption spectra of alcoholic solutions of nitrobenzene, azoxybenzene, azobenzene, hydrazobenzene, and aniline are given in tables and curves. The extinction coefficients are calculated (cf. this vol., A., ii, 7). E. E. T.

The Constitution of Di*cyclo*pentadiene. H. Staudinger and A. Rheiner (*Helv. Chim. Acta*, 1924, **7**, 23—31).—Commercial di*cyclo*pentadiene can be separated by fractional distillation at a low pressure into two isomerides; the higher-boiling fraction, the β-form, has m. p. 19·5°, whilst the α-form, the known di*cyclo*pentadiene, has m. p. 32·5°. These two forms probably correspond with the formulæ

$$CH<\begin{matrix}CH_2\cdot CH\cdot CH\cdot CH_2\\ CH-CH\cdot CH-CH\end{matrix}>CH$$

and



$$CH<\begin{matrix}CH-CH\cdot CH\cdot CH_2\\ CH_2\cdot CH\cdot CH-CH\end{matrix}>CH.$$

Each of these isomerides should exist in two stereoisomeric forms. The two isomerides which were isolated cannot be stereoisomerides, since by partial reduction they both give the same *dihydrodi*cyclo*pentadiene*, white crystals, m. p. 57°. This compound can be distilled at atmospheric pressure (b. p. 183·5—184·5°) and is therefore more stable than di*cyclo*pentadiene, which, under these conditions, is completely depolymerised. Dihydrodi*cyclo*pentadiene is decomposed into *cyclo*pentadiene and *cyclo*pentene when its vapour is passed over a red-hot platinum spiral. Further reduction of dihydrodi*cyclo*pentadiene gives the known tetrahydrodi*cyclo*pentadiene, which is still more stable, and is with difficulty decomposed to *cyclo*pentene. The disruption of the *cyclo*butane ring in di*cyclo*pentadiene is attributed to the influence of the double bond in the β-position to the carbon linking. A similar cause is responsible for the ready decomposition of limonene, caoutchouc, and hexaphenylethane. *Tri*cyclo*pentadiene* is obtained when di*cyclo*pentadiene is heated in a sealed tube at 170° for some hours. It forms colourless crystals, m. p. 60°, b. p. 90—92°/0·06 mm. It is more stable to heat than di*cyclo*pentadiene or *tetra*cyclo*pentadiene*. The latter is obtained by heating di*cyclo*pentadiene for a longer time at 180°. It has m. p. 188—190°, and when heated at 180—200° decomposes smoothly into *cyclo*pentadiene. When reduced with hydrogen and platinum black, it gives *tetrahydrotetra*cyclo*pentadiene*, m. p. 200—202°, which can be distilled unchanged. Still further polymerisation of di*cyclo*pentadiene results in the production of *poly*cyclo*pentadiene*, an insoluble, infusible, white, crystalline powder, decomposing at 285°. E. H. R.

The Constitution of the Disulphoxides. I. S. SMILES and D. T. GIBSON (*J. Chem. Soc.*, 1924, **125**, 176—183).—The various formulæ given to the disulphoxides at different times are discussed, and an attempt is made to decide between the symmetrical and unsymmetrical formulæ, $R\cdot SO_2\cdot SR$ and $R\cdot SO\cdot SO\cdot R$. Considered as a whole, the evidence at present available favours the unsymmetrical type. The reaction of mercaptans with disulphoxides is studied, and using a mercaptan $R'\cdot SH$, where R' is different from the group R in the disulphoxide it is found that high yields of the sulphinic acid, $R\cdot SO_2H$, are obtained with a mixed disulphide, $R'S\cdot SR$, but no sulphinic acid, $R'\cdot SO_2H$. 2 : 5-*Dichlorobenzenesulphinic acid*, $C_6H_3Cl_2\cdot SO_2H$, forms crystals, m. p. 122°. 2 : 5 : 2′ : 5′-*Tetrachlorodiphenyl disulphoxide*, $(C_6H_3Cl_2)_2S_2O_2$, crystallises in needles, m. p. 128°; 3 : 3′-*dicarboxydiphenyl disulphoxide*, $(C_6H_4\cdot CO_2H)_2S_2O_2$, has m. p. 229°; 2 : 5-*dichloro*-4′-*methyldiphenyl disulphide* forms needles, m. p. 71—72°; *phenyl*-2-*naphthyl disulphide*, m. p. 74—75°; 2 : 5-*dichloro*-3′-*nitrodiphenyl disulphide*, needles, m. p. 89—91°; 9-*anthryl*-4-*tolyl disulphide*, bright yellow needles, m. p. 98—99°; 3-*carboxyphenyl*-4-*tolyl disulphide*, crystals, m. p. 140°. F. G. P.

Preparation of Diphenyl. C. H. LOWE and C. JAMES (*J. Amer. Chem Soc.*, 1923, **45**, 2666—2669).—When using the apparatus previously described (*J. Amer. Chem. Soc.*, 1917, **39**, 933) for the preparation of diphenyl, difficulties arise owing to local heating and sagging of the filament of the heating element, with resulting short-circuiting. A filament support is now described in which these defects are eliminated. It is claimed that by maintaining the filament at a yellowish-red heat very good yields of diphenyl may be obtained from commercially pure benzene, which need not be anhydrous. The addition of more water does not hasten the reaction. W. S. N.

Anthracenemonosulphonic Acids. Sulphonation of Hydrocarbons in a Basic or Neutral Medium. M. BATTEGAY and P. BRANDT (*Bull. Soc. chim.*, 1923, **33**, [iv], 1667—1678; cf. A., 1922, i, 1001).—In the direct sulphonation of anthracene by means of fuming sulphuric acid or chlorosulphonic acid, the separation of the two isomeric anthracenemonosulphonic acids is effected by means of the barium in preference to the sodium salts. The position of the entering sulphonic group was determined by conversion of the acids into the corresponding α- and β-chloroanthraquinones under the influence of nascent chlorine. The two acids are formed in almost equal proportions; elevation of temperature does not appear to favour a greater production of the β-isomeride, as in the case of naphthalene (Fierz and Weissenbach, A., 1920, i, 430), although accurate observation is difficult by reason of the disulphonation of anthracene at temperatures above 100°. When, however, anthracene-α-sulphonic acid was heated in 96% sulphuric acid at temperatures ranging from 150—180° and subsequently transformed into dichloroanthraquinone, the product appeared to consist wholly of the 1 : 5- and 1 : 8-isomerides, thus indicating that no shifting of the sulphonic group from the α- to the β-position had occurred. Sulphonation in presence of mercury, mercurous sulphate, or mercurous oxide resulted in a slight increase in yield without any appreciable effect on the relative proportions of the isomerides. Attempts at sulphonation in a neutral or basic medium (cf. Battegay and Brandt, A., 1922, i, 1001) were made, pyridine being used as the medium in place of the acetic acid employed in the work described above. Experiments were carried out over a temperature range of 95—115° and with varying proportions of the solvent. The best yields were obtained when a portion of the pyridine was replaced by a neutral solvent of higher b. p. In the presence of petroleum at 165—175°, almost the whole of the resulting anthracenesulphonic acid is the α-isomeride, and the addition of mercury compounds has no appreciable influence on the yield or the course of the reaction. When nitrobenzene is used, the yield is considerably smaller. A brief note on the application of Wagner's theory (A., 1886, 708) to the mechanism of the reaction is appended.

Anthracene-α-sulphonic chloride, m. p. 90°, was prepared, but probably in an impure condition; on being heated with alcoholic ammonia, it yields the corresponding *sulphonamide*, brown crystals, m. p. 205° (cf. Heffter, A., 1895, i, 671). H. J. E.

Reactions of Strongly Electropositive Metals with Organic Substances in Liquid Ammonia Solution. IV. Action of the Alkali Metals on Triphenylmethyl and its Compounds. C. A. Kraus and T. Kawamura (*J. Amer. Chem. Soc.*, 1923, **45**, 2756—2763).—The strongly electropositive metals react with triphenylmethyl chloride in liquid ammonia forming the compound of the metal with the triphenylmethyl group, *e.g.*, $CPh_3{\cdot}Na$. The *sodium* compound has been obtained in red needles. With ammonium chloride in liquid ammonia the sodium derivative gives an immediate pink precipitate which turns white on standing owing to production of triphenylmethane, $CPh_3{\cdot}Na \longrightarrow CPh_3{\cdot}NH_4 \longrightarrow CPh_3H + NH_3$. The sodium compound is unstable, but the *potassium* derivative is stable even at 100°. Triphenylmethyl is obtained by the action of triphenylmethyl chloride on sodium triphenylmethyl in the presence of toluene; this reaction does not take place if the sodium compound is replaced by the potassium derivative. Bromobenzene converts sodium triphenylmethyl into tetraphenylmethane. The mechanism of the reduction of organic halides by means of the alkali metals in liquid ammonia solution is discussed. F. G. P.

The Preparation and Properties of Organic Stannichlorides. VI. The Action of Sulphuric Acid on certain Stannichlorides. The Formation of Stannisulphates. J. G. F. Druce (*Chem. News*, 1924, **128**, 33—34; cf. A., 1922, i, 1206).—Stannisulphates of some organic bases can be obtained by the action of concentrated sulphuric acid on the corresponding stannichloride. The stannisulphate crystallises from the sulphuric acid after the addition of ether. *Aniline stannisulphate*, $(PhNH_2)_2,H_2Sn(SO_4)_3$, forms grey, deliquescent crystals. m-*Phenylenediamine stannisulphate*,

$$C_6H_4(NH_2)_2,H_2Sn(SO_4)_3,$$

does not melt below 300°. *Quinoline stannisulphate*,

$$(C_9H_7N)_2,H_2Sn(SO_4)_3,$$

forms colourless, deliquescent needles, m. p. 124°. Potassium and calcium stannisulphates can be prepared in the same way from the stannichlorides. E. H. R.

The Mechanism of the Hofmann Rearrangement of Methylaniline Hydrochloride. J. W. Howard and C. G. Derick (*J. Amer. Chem. Soc.*, 1924, **46**, 166—177).—The investigation was undertaken to confirm Hofmann's original views as to the nature of the change (*Ber.*, 1871, **4**, 742). It was found that in the rearrangement methyl chloride dissociates from the methylaniline hydrochloride and combines with a second molecule, forming phenyltrimethylammonium chloride; this compound then undergoes rearrangement. No rearrangement takes place at 220—250° unless the heating is continued for ninety-six hours. At 300°, however, rearrangement takes place, and is somewhat affected by time, but temperature is the chief factor. Neither methylaniline nor dimethylaniline rearranges. A quantitative separation and determination of the three classes of amine by means of benzenesulphonyl chloride has been worked out. F. A. M.

***p*-Bromophenyltrimethylammonium Perhalides.** T. H. Reade (*J. Chem. Soc.*, 1924, **125**, 148—157; cf. T., 1923, **123**, 141).—The degradation of perhalides by acetone has yielded analogous quaternary ammonium salts in the case of this series, the corresponding *p*-iodo series, and the simple phenyltrimethylammonium series itself, the part removed by acetone being either iodine chloride or bromide or chlorine. The points of difference between the *p*-bromo-series and the unsubstituted series are that *p*-bromophenyltrimethylammonium bromide di-iodide yielded the *p*-bromophenyltrimethylammonium bromide on treatment with acetone, whereas its analogue in the unsubstituted phenyl series was not attacked, and that well-defined double perhalides have been obtained in several reactions. Chlorine replaces *N*-halogen in iodides and periodides, replaces *N*-bromine only when iodine is also present, and replaces added halogens in perbromides. Both bromine and iodine replace *N*-chlorine to an appreciable extent, and iodine replaces *N*-bromine in one instance. p-*Bromophenyltrimethylammonium methyl sulphate*, $C_6H_4Br{\cdot}NMe_3{\cdot}SO_4Me$, white crystals, m. p. 208°, when treated with bromine in hydrobromic acid solution, gives the *perbromide*, $C_6H_4Br\cdot NMe_3Br_3$, orange-red leaflets, m. p. 175°. When warmed with acetone this perbromide yields the *bromide*, $C_6H_4Br\cdot NMe_3Br$, m. p. 210°. Iodine in acetic acid gave $C_6H_4Br\cdot NMe_3Br,IBr$; chlorine similarly yielded

$$C_6H_4Br\cdot NMe_3Br\cdot Cl_2,$$

lemon-yellow plates, m. p. 158°. The bromo-dichloride, the perbromide, and the bromodi-iodide are obtained by the action of halogens on the simple bromide of m. p. 210°. Chlorine with the *p*-bromophenyltrimethylammonium iodide gives the *chloride iodotrichloride*, $C_6H_4Br\cdot NMe_3Cl,ICl_3$, m. p. 187°, bromine gives the *bromoiodobromide*, m. p. 185°, iodine the *tri-iodide*, m. p. 172°. The *chloride iodochloride*, $C_6H_4Br\cdot NMe_3Cl,ICl$, m. p. 177°, is obtained by the action of chlorine on the simple iodide, and on treatment with bromine gives a yellow double perhalide,

$$C_6H_4Br\cdot NMe_3Cl,ICl+C_6H_4Br\cdot NMe_3Br,ICl.$$

Acetone converts the chloride iodochloride into the simple *chloride*, m. p. 199°; this with iodine gives the double compound, $C_6H_4Br\cdot NMe_3I_3 + C_6H_4Br\cdot NMe_3I_5$. The *bromide iodobromide*, $C_6H_4Br\cdot NMe_3Br,IBr$, obtained by the action of bromine on the iodide, crystallises in orange plates, m. p. 189° (decomp.). With chlorine, it yields $C_6H_4Br\cdot NMe_3Cl,ICl_3$; bromine has no action, iodine gives a red double perhalide, $C_6H_4Br\cdot NMe_3Br,IBr+C_6H_4Br\cdot NMe_3BrI_2$. The *bromide di-iodide*, $C_6H_4Br\cdot NMe_3BrI_2$, obtained by the action of iodine on the bromide, has m. p. 172° (decomp.). With chlorine, it yields yellow needles of

$$C_6H_4Br\cdot NMe_3Cl,ICl_3,$$

m. p. 186°, with bromine, the *bromide iodobromide*, m. p. 189°, and with iodine the tri-iodide. The *bromide iodochloride*, $C_6H_4Br\cdot NMe_3Br,ICl$, is obtained by the action of iodine monochloride on the bromide, in the form of yellow crystals, m. p. 178—179°. With chlorine, it yields $C_6H_4Br\cdot NMe_3Cl,ICl_3$, m. p. 186°; with bromine a mixture of the bromide iodobromide and bromide iodochloride, and with iodine a mixture of bromide di-iodide and bromide iodochloride. The *bromide dichloride*, $C_6H_4Br\cdot NMe_3Br,Cl_2$, results by the action of chlorine on the bromide. It forms greenish-yellow crystals, m. p. 158°. Neither chlorine nor bromine has any action on it; with iodine, it yields the *bromide iodochloride*, m. p. 178°. F. G. P.

p-Iodophenyltrimethylammonium Perhalides. T. H. READE and S. A. SIM (*J. Chem. Soc.*, 1924, **125**, 157—160).—Chlorine converts *p*-iodophenyltrimethylammonium iodide into the chloride iodotrichloride, $C_6H_4INMe_3Cl\cdot ICl_3$, and this can be degraded by ethyl malonate, yielding the dichloro-iodide, $C_6H_4I\cdot NMe_3Cl\cdot ICl$. With hot glacial acetic acid, the dichloro-iodide yields a double perhalide, $C_6H_4I\cdot NMe_3Cl_2I+C_6H_4I\cdot NMe_3ClI_2$. p-*Iodophenyltrimethylammonium chloride iodotrichloride*,

$$C_6H_4I\cdot NMe_3Cl\cdot ICl_3,$$

crystallises in yellow needles, m. p. 187°; on treatment with ethyl malonate under reduced pressure it gives the *chloride–iodochloride*, yellow crystals, m. p. 184°. The *tri-iodide* crystallises in brown leaflets, m. p. 189°. A method for determining the ionisable halogen in the perhalides is given. F. G. P.

Synthesis of Indanylamine and of its *N*-Substituted Derivatives. C. Courtot and A. Dondelinger (*Compt. rend.*, 1924, **178**, 493—495; cf. A., 1923, i, 1090).—1-Chloroindane is converted by dry liquid ammonia in a closed vessel, at the ordinary temperature, into 1-indanylamine, b. p. 96—97°/8 mm., and a little di-indanylamine, m. p. 84—85°. Methyl-, dimethyl-, ethyl- and diethyl-amines similarly convert chloroindane into *methylindanylamine*, b. p. 106—107°/15 mm., *dimethylindanylamine*, b. p.1 00°/10 mm., *ethylindanylamine*, b. p. 106—107°/7 mm., and *diethylindanylamine*, b. p. 112—113°/8 mm., respectively, all four amines being colourless liquids.

Indene, on hydrogenation in presence of platinum black, affords indane (in 97% yield), which does not react with magnesium ethyl bromide at 135° (cf. Grignard and Courtot, A., 1911, i, 193). The reactivity of the methylene group in indene is therefore due to the presence of unsaturation in the 5-membered ring. E. E. T.

Preparation of 3 : 3′-Diaminodiphenylsulphone by Electrolytic Reduction of 3 : 3′-Dinitrodiphenylsulphone. J. Lacroix (*Compt. rend.*, 1924, **178**, 483—486).—The electrolytic reduction of 3 : 3′-dinitrodiphenylsulphone to the diamino-derivative is best effected (yield, 94·5%) by the use of an alcoholic solution of the dinitro-compound acidified wth hydrochloric acid as the cathode liquid, with a cathode consisting of nickel foil covered with spongy tin. The anode is of lead immersed in 10% sulphuric acid. The cathode liquid is maintained at a temperature of 68—72° and well agitated. A. B. H.

Chloronitrobenzenes and Thiocarbamides. J. Taylor and A. E. Dixon (*J. Chem. Soc.*, 1924, **125**, 243—250).—Neither *o*- nor *p*-chloronitrobenzene nor 2 : 5-dichloronitrobenzene combines with thiocarbamide. 1-Chloro-2 : 4-dinitrobenzene unites with thiocarbamide and with phenylthiocarbamide to form additive salts, from which alkali hydroxides eliminate hydrogen chloride, the dinitrophenyl residue breaking off as dinitrophenyl mercaptan. With thiocarbanilide, chlorodinitrobenzene gives mainly phenylthiocarbimide and dinitrodiphenylamine, $(NO_2)_2C_6H_3$·NHPh. Picryl chloride unites with thiocarbamide to form an *additive* compound, from which a *picrate* and a *salicylate* were obtained. Phenylthiocarbamide gave little additive salt, thiocarbanilide none. The picryl compounds are unstable, decomposing readily into dipicryl sulphide and a dark-coloured powder. In no case was an *N*-substituted thiocarbamide obtained, the behaviour of dinitrochlorobenzene and picryl chloride thus more resembling that of an alkyl halide than of an acid chloride. The *picrates* of the compounds obtained from 1-chloro-2 : 4-dinitrobenzene with thiocarbamide and phenylthiocarbamide are yellow compounds, m. p. 192—193° and 160—161°, respectively. The *picrate* derived from picryl chloride and thiocarbamide has m. p. 149—150°, the *salicylate*, m. p. 76°. F. G. P.

The Decomposition of Substituted Carbamyl Chlorides by Hydroxy-compounds. I. The Reaction between Phenylmethylcarbamyl Chloride and Ethyl Alcohol at Different Temperatures. T. W. PRICE (*J. Chem. Soc.*, 1924, **125**, 115—129).—The reaction between phenylmethylcarbamyl chloride (m. p. 87·5°) and alcohol is very slow at temperatures below the boiling point of alcohol, and was consequently studied in sealed tubes at 100°, 90°, 80°, and 70°. Under these conditions, the carbamyl chloride first reacts with the alcohol to form phenylmethylurethane together with hydrogen chloride, which then reacts further with alcohol to form ethyl chloride and water. The first reaction was studied separately by adding dimethylaniline to the reaction mixture to combine with the hydrogen chloride and prevent the formation of ethyl chloride. The velocity of the reaction between the alcohol and the carbamyl chloride was found to vary with the amount of dimethylaniline added, being slower in presence of more base. Three series of experiments were therefore made at 100° with different amounts of dimethylaniline, and the velocity constant of the reaction in absence of dimethylaniline was found by extrapolation to be $k_1=0{\cdot}0426$ at 100°. As this value was in good agreement with the value obtained by calculation from the study of the combined reaction, measurements in presence of varying quantities of dimethylaniline were omitted at the other temperatures. The position of the reaction under these conditions was determined by titration of the dimethylaniline hydrochloride present at any given moment, the initial concentration of the carbamyl chloride in the alcohol being in all cases $N/2$. The action of hydrogen chloride ($N/2$) on ethyl alcohol was investigated separately. The velocity constant fell steadily at each temperature, the means of the first three values being $k_2 = 0{\cdot}0102$ at 100°, 0·00443 at 90°, 0·00162 at 80°, and 0·000521 at 70°.

The whole reaction was then studied by determining the amounts of carbamyl chloride, hydrogen chloride, and ethyl chloride present at any instant. The hydrogen chloride was determined by direct titration, and the carbamyl chloride by hydrolysis with excess of potassium hydroxide after removal of the ethyl chloride, followed by titration with silver nitrate. The velocity constants of the first reaction, calculated from the amounts of carbamyl chloride present, were $k_1=0{\cdot}0427$ at 100°, 0·0196 at 90°, 0·00873 at 80°, and 0·00329 at 70°. Expressions deduced for the amounts of the various reactants present at any time from the values of k_1 and k_2, as well as for the maximum amount of hydrogen chloride present and the time taken for this maximum to be reached, gave satisfactory agreement with experimental results, and the variation of temperature coefficient for each reaction was shown to be in accordance with Lewis' deductions. F. G. W.

Esterification of *cyclo*Hexanol and of some of its Homologues. (MLLE.) G. CAUQUIL (*Compt. rend.*, 1924, **178**, 323—326).—*cyclo*Hexanol, 2-methyl*cyclo*hexanol, or 3 : 4-dimethyl*cyclo*hexanol was heated, at 95°, with an equivalent weight of acetic acid until equilibrium was attained, when it was found that 55·6%, 49·8%, and 47·5% of the three alcohols, respectively, had undergone esterification. E. E. T.

The Catalytic Hydrogenation of Organic Fluoro-derivatives. III. The Hydrogenation of ω-Trifluoro-*m*-cresol. F. SWARTS (*Bull. Soc. chim. Belg.*, 1923, **32**, 367—376; cf. A., 1921, i, 656).—The hydrogenation of ω-trifluoro-*m*-cresol in the presence of platinum black proceeds in two directions, one resulting in the formation of ω-trifluoromethyl*cyclo*hexanol, the other in the production of ω-trifluoromethyl*cyclo*hexane and water, the group CF_3– being unaffected. The relative proportions of the *cyclo*hydrocarbon and *cyclo*alcohol are not constant, increase of temperature favouring the production of the hydrocarbon. In the case of ω-trifluoro-*m*-cresol, a thermal coefficient of acceleration is observed, whilst the velocity of absorption of the hydrogen by the trifluoromethyl*cyclo*hexane varies little with the temperature. An attempt is made to deduce a formula by means of which the thermal coefficient of the reaction can be calculated.

*Trifluoromethyl*cyclo*hexan-3-ol,* $CF_3{\cdot}C_6H_{10}{\cdot}OH$, is a viscous liquid, b. p. 183—184°; its *benzoyl* derivative crystallises in prisms, m. p. 55°, d^{17} 1·2611. The *acetyl* derivative has b. p. 192·5—194°. *Trifluoromethyl*cyclo*hexan-3-one* is obtained by oxidising the corresponding *cyclo*hexane with chromic acid; it boils at 173—174°/746 mm., d^{16} 1·242. Its *semicarbazone* melts at 190°. F. G. P.

The Lead Derivative of Trinitroresorcinol. C. A. TAYLOR and W. H. RINKENBACH (*U.S. Bur. Mines, Repts. Investigations*, 1923, No. 2533).—The *lead* derivative of trinitroresorcinol is obtained in 94·4% yield, as fine, light orange-coloured crystals, *d* 3·09, by mixing boiling solutions of lead nitrate, trinitroresorcinol, and sodium carbonate, to which glacial acetic acid has been added. Its explosion temperature is 293° and rate of detonation 2097—2209 m. per second. CHEMICAL ABSTRACTS.

The Influence of Hydrogen Concentration on the Autoxidation of Quinol. A Note on the Stability of the Quinhydrone Electrode. V. K. LAMER and E. K. RIDEAL (*J. Amer. Chem. Soc.*, 1924, **46**, 223—231).—The rate at which quinol reacts with molecular oxygen has been followed by shaking borate buffers, $0{\cdot}01M$ with respect to quinol, with oxygen. The rate does not become appreciable until the solution is more alkaline than p_H 7·3 or 7·8 for air. The rate of reaction is highly sensitive to further increase of p_H value, being proportional to $[H^+]^{3/2}$, where $[H^+]$ is the hydrogen-ion concentration, for the region investigated. A mechanism involving complex formation of the primary and secondary ions is suggested to explain this relationship, such as: $2H_2C_6H_4O_2 \longrightarrow 3H^+ + HC_6H_4O^- + C_6H_4O^= \longrightarrow$ complex ion; complex$+2O_2 \longrightarrow 2$ quinone$+H_2O_2$. F. A. M.

Arylazides. III. Quinol Ethers from *p*-Methylated Arylazides. E. BAMBERGER and J. BRUN (*Helv. Chim. Acta*, 1924, **7**, 112—122).—A detailed account of experiments the results of which have already been recorded (A., 1921, i, 721). E. H. R.

Arylazides. IV. Iminoquinol Ethers from *p*-Methylated Arylazides. E. BAMBERGER, J. BRUN, and A. HARTMANN (*Helv. Chim. Acta*, 1924, 7, 123—131).—A detailed account of work already published (A., 1921, i, 721). E. H. R.

Electrochemical Oxidation of Alkyl Ethers of Phenol and of the Three Isomeric Dihydroxybenzenes. F. FICHTER and W. DIETRICH (*Helv. Chim. Acta*, 1924, 7, 131—143).—Anodic oxidation of anisole in suspension in dilute sulphuric acid, using a lead peroxide anode, results in a high yield of benzoquinone, up to 71% of theory under favourable conditions. This result is obtained using a diaphragm; in absence of a diaphragm, a mixture of quinhydrone and quinol is obtained. Quinol monomethyl ether is probably formed as an intermediate product, since this is converted practically quantitatively into benzoquinone by anodic oxidation. The methyl group is oxidised to methyl alcohol. When a platinum anode is used the yield of benzoquinone is very small; some formaldehyde is formed but the principal product is carbon dioxide. Phenetole and phenyl *iso*amyl ether give smaller yields of benzoquinone, whilst the alkyl group is in each case oxidised to the corresponding acid. Quinol dimethyl ether gives benzoquinone, the best yield being 48·6% of theory.

By the oxidation of guaiacol, using a diaphragm, at first only fumaric acid could be obtained; this, in absence of a diaphragm, was reduced to succinic acid. By stopping the oxidation at an early stage, however, an oily product was obtained from which a diphenyl derivative, *diguaiacol*, was isolated. This is probably 4 : 4′-*dihydroxy*-3 : 3′-*dimethoxydiphenyl*; it crystallises in slender needles, m. p. 166°, and gives an orange colour with ferric chloride. Its *diacetyl* derivative crystallises in leaflets, m. p. 198°, and its *dibenzoyl* derivative in white needles, m. p. 203°. By demethylation, it gives a *tetrahydroxydiphenyl* (? 3 : 4 : 3′ : 4′), needles, m. p. 134°, giving an emerald-green coloration with ferric chloride. Its *tetra-acetyl* derivative has m. p. 161°. Further methylation of diguaiacol converts it into *diveratrole*, or *tetramethoxydiphenyl*, colourless tablets or leaflets, m. p. 130°. Anodic oxidation of veratrole gives rise to some diveratrole, but in addition, partial demethylation occurs with formation of a *hydroxytrimethoxydiphenyl*, which gives an *acetyl* derivative, pale yellow leaflets, m. p. 116°. Anodic oxidation of resorcinol monomethyl ether gives an amorphous *dihydroxydimethoxydiphenyl* which, when demethylated, gives 2 : 4 : 2′ : 4′-tetrahydroxydiphenyl (2 : 4 : 2′ : 4′-diresorcinol). E. H. R.

The Catalytic Condensation of Acetylene with Phenols. H. H. WENZKE and J. A. NIEUWLAND (*J. Amer. Chem. Soc.*, 1924, 46, 177—181).—Acetylene condenses with phenols and cresols in 95% alcoholic solution, in presence of sulphuric acid and mercury salts, to form uncrystallisable resins. The di- and trihydroxybenzenes react even more readily. With β-naphthol, acetylene condenses to form an acetal and some ethylidenedi-β-naphthol. Resorcinol condenses with acetylene to form ethylidenediresorcinol (as-2 : 4 : 2′ : 4′-*tetrahydroxydiphenylethane*), which loses water spontaneously to form 3 : 6-*dihydroxy-9-methylxanthene*, soluble in water and alkalis (decomp. 230—240°). On heating with stannic chloride at 160—180°, it oxidises to form 6-*hydroxy-9-methylfluorone*, the solutions of which resemble that of fluorescein.

The presence of nitro- and sulphonic groups prevents the absorption of acetylene by a phenolic compound. No cases have been noted where the acetylene substitutes in a meta-position to another group. Phenetole does not react with acetylene under the above conditions. F. A. M.

The Hydrobenzoin Rearrangement. I. Hydroanisoin. M. Tiffeneau and A. Orékhoff (*Bull. Soc. chim.*, 1923, **33**, [iv], 1832—1838).—According to Russell (*Annalen*, 1869, **151**, 25), hydroanisoin, on dehydration, affords deoxyanisoin (m. p. 95°). Irvine and Moodie (T., 1907, **91**, 536) found for the latter compound the m. p. 108—109°. It is now shown that Russell's compound is *dianisylacetaldehyde*, $(OMe\cdot C_6H_4)_2CH\cdot CHO$, as would have been expected (cf. Orékhoff and Tiffeneau, A., 1921, i, 566). The aldehyde (needles, m. p. 104—105°; *semicarbazone*, m. p. 140—141°) is also obtained by treating magnesium *p*-anisyl bromide with ethyl ethoxyacetate, and the product of this interaction with formic acid. On oxidation, the aldehyde affords dianisyl ketone, and with magnesium phenyl bromide gives *α-phenyl-*ββ-di-*p-anisylethyl alcohol* (needles, m. p. 139—140°). Hydroanisoin (m. p. 170—171°), on heating with 50% sulphuric acid, affords the above aldehyde, *iso*hydroanisoin (m. p. 125—126°) behaving similarly.

Dianisyl ketone with magnesium methyl iodide is converted into *dianisylethylene*, $(OMe\cdot C_6H_4)_2C{:}CH_2$ (m. p. 142—143°), the latter, when treated with mercuric oxide in presence of water and iodine, affording an iodohydrin (not isolated) which is converted by silver nitrate into deoxyanisoin. E. E. T.

Semi-pinacolic Transformation. Necessity for the Presence of the Phenyl Group in Semi-pinacolic Transformations. (Mlle.) J. Lévy (*Bull. Soc. chim.*, 1923, **33**, [iv], 1655—1666; cf. Tiffeneau and Lévy, A., 1923, i, 788, 789).—In the aromatic series, the stability of the secondary hydroxyl group in respect of semi-pinacolic transformations appears to be conditioned by the nature of the aryl group linked to the secondary carbon atom. The author has studied the dehydration of six tri-substituted glycols and draws the conclusion that in addition to transpositions involving only phenylic groups in which the shifting of a group occurs only when the group capable of migration is arylic, others take place only in the cyclic series, but this is limited to cases in which the aryl group occupies one definite position. In these cases, the migratory group may be either cyclic or acyclic. Experimental details of the dehydration of the glycols are given (cf. A., 1921, i, 860). The following substances are described: βγ-*di-*

hydroxy-α-phenyl-γ-methylbutane, needles, m. p. 64—65°; *ethyl benzylglycollate*, b. p. 170—173°/30 mm.; *benzyl* iso*propyl ketone*, b. p. 234—235°; *semicarbazone*, m. p. 140—141°; *α-phenyl-γ-ethylpentane-βγ-diol*, small needles, m. p. 79—80°, yielding on dehydration by means of sulphuric acid an oil, b. p. 160—170°/50 mm., which forms a semicarbazone, m. p. 160—161°; *αδ-diphenyl-γ-benzylbutane-βγ-diol*, crystals, transformed by concentrated sulphuric acid into a substance, $C_{23}H_{20}$, m. p. 94—95°, of unknown constitution; *α-methylhexane-β-ol*, b. p. 140—142°/760 mm., prepared by the action of magnesium butyl bromide on acetone, yields on dehydration a *methyl-Δ^{β}-hexene*, b. p. 95—98°/760 mm., which on treatment with hypoiodous acid yields an *iodohydrin*; this is converted into a ketone on treatment with silver nitrate without undergoing any transposition. H. J. E.

3 : 4-Dihydroxyphenylmethylaminoethanol (Adrenaline). I. HOSHINO and DAIICHI SEIYAKU KABUSHIKI KAISHA (Japan. Pat. 42351).—Adrenaline is prepared from methylaminoacetyl-3 : 4-dihydroxybenzene by reducing with hydrogen, using as a catalyst colloidal solutions of metals of the platinum group, the finely powdered metals, or nickel or carbon bearing these metals. The product is purer than that obtained by Stolz's method and the yield almost theoretical. K. K.

Cyclic Trimethylene [*cyclo*Propane] Compounds. P. BRUYLANTS (*Bull. Soc. chim. Belg.*, 1923, **32**, 358—367).—Bromination (in direct sunlight) of *cyclo*propane-1-carboxylic chloride, until the liquid boils at 135—140°, followed by treatment of the product with methyl alcohol, gives a mixture of methyl *cyclo*propane-1-carboxylate, *methyl* 1-*bromo*cyclo*propane*-1-*carboxylate* (a colourless, mobile liquid, b. p. 168°/702 mm., d_4^{20} 1·545, n_D^{20} 1·4784), and *methyl αγ-dibromobutyrate*. The latter (b. p. 113—114°/14 mm.) is the only product of bromination in the dark, and was identified by conversion into αγ-dibromobutyramide (m. p. 80—82°). cyclo*Propane*-1-*carboxylic anhydride*, which, on bromination, gives only open-chain derivatives, is a colourless liquid, b. p. 232°/752 mm., d_4^{20} 1·1132, n_D^{20} 1·4628. The corresponding *ethyl* ester has b. p. 178°/758 mm., d_4^{20} 1·428, n_D^{20} 1·4678. The esters are converted by ammonia into the *amide* (needles, m. p. 108°), and by concentrated sodium hydroxide into the *acid*, m. p. 77°. Magnesium methyl bromide converts the methyl ester into the *bromohydrin* (b. p. 171—172°/762 mm.), the latter with acetic anhydride giving the *bromo-acetin* (b. p. 180—182°, d_4^{20} 1·327, n_D^{20} 1·4731), and with alkali hydroxide the *oxide*,  $\left.\begin{matrix}CH_2\\|\\CH_2\end{matrix}\right>C\underset{\diagdown O \diagup}{—}CMe_2$, b. p. 121—125°, d_4^{20} 0·886, n_D^{20} 1·419. Digestion of the oxide with dilute sulphuric acid, followed by addition of semicarbazide, gives a *semicarbazone* (?), m. p. 115—140° (very indefinite). Electrolysis of potassium *cyclo*propanecarboxylate yields the free acid and a little *cyclo*propane.

F. G. P.

Preparation and Properties of some Organic Uranyl Salts and, in particular, of Uranyl Benzoates and Salicylates. G. COURTOIS (*Bull. Soc. chim.*, 1923, **33**, [iv], 1761—1773).—A continuation of previous work (A., 1914, i, 799, 802). When the hydroxide, UO_3,H_2O, is dissolved in a hot aqueous solution of benzoic acid, and the solution evaporated, *uranyl benzoate*, $(Ph{\cdot}CO_2)_2UO_2$ (yellow crystals, stable at 100°), separates, together with benzoic acid, which may be extracted with benzene. On further evaporation, the *acid* salt, $(Ph{\cdot}CO_2)_2UO_2,Ph{\cdot}CO_2H$, separates, the latter salt also being obtained if uranyl hydroxide is dissolved in boiling benzoic acid. Uranyl benzoate is sparingly soluble in water, the solution depositing a basic salt on standing. Below 5°, the saturated aqueous solution deposits the *dihydrate*, which becomes anhydrous on keeping at the ordinary temperature, and dissolves in ether to give a solution which rapidly deposits a yellow, crystalline compound, $(Ph{\cdot}CO_2)_2UO_2,2Et_2O$. The latter is also formed when a concentrated aqueous solution of the benzoate is shaken with ether, and slowly loses ether of crystallisation on keeping (rapidly at 100°).

Uranyl hydroxide dissolves in a hot alcoholic solution of benzoic acid, the *compound*, $(Ph{\cdot}CO_2)_2UO_2,EtOH$ (pale yellow crystals, from which ether displaces the alcohol of crystallisation), separating on cooling. This salt, on crystallisation from water or from chloroform, or on heating at 100°, loses its alcohol of crystallisation.

When aqueous solutions of uranyl benzoate are concentrated by protracted (hot) evaporation, a yellow, crystalline, *basic* salt, $(PhCO_2)_2UO_2,UO_3,H_2O$, separates, and may be freed from accompanying uranyl benzoate by extracting the latter with alcohol. Prolonged heating with water converts the basic salt into uranyl hydroxide.

Aqueous solutions of uranyl benzoate are unaffected by sunlight, whilst alcoholic solutions afford a violet precipitate of uranoso-uranic oxide, the latter becoming yellow on washing with water containing dissolved air.

Uranyl salicylate, $(OH{\cdot}C_6H_4{\cdot}CO_2)_2UO_2$, separates as orange-yellow crystals, readily soluble in methyl or ethyl alcohol, from the warm solution obtained by heating uranyl hydroxide with aqueous salicylic acid. The mother-liquors, on cooling, deposit the *dihydrate* of the above salt in the form of yellow crystals, giving red solutions in methyl or ethyl alcohol and becoming anhydrous at 140—150°, with slight decomposition. Aqueous solutions of uranyl salicylate, on boiling, acquire a red colour. Neither aqueous nor alcoholic solutions of the salt are affected by sunlight, a fact that distinguishes the salt from all other uranyl salts studied. E. E. T.

Stability of Solutions of some Organic Uranyl Salts in Absence or in Presence of Light. G. COURTOIS (*Bull. Soc. chim.*, 1923, **33**, [iv], 1773—1785).—Previous results (A., 1914, i, 799 and 802; and preceding abstract) are re-stated and slightly extended. It is shown that saturated aqueous solutions of the following uranyl salts are unstable even in absence of light, giving crystalline basic salts (already described): Formate, acetate, benzoate, glycollate, and citrate. The other uranyl salts examined (propionate, butyrate, lactate, quinate, salicylate, oxalate, and tartrate) are stable in the dark in aqueous solution.

Sunlight, in absence of air, causes the reduction of all the above salts, with the exception of the benzoate and salicylate. The stability of the latter may be due to the "antioxygen" property of the salicylate residue. Contrary to the view of Aloy and Rodier (A., 1920, ii, 182), decomposition by sunlight does not depend on the hydroxylic character of the salt, as in the case of the tartrate, since uranyl propionate, butyrate, etc., are decomposed in aqueous solution under the influence of sunlight. In these cases, the violet hydrated uranoso-uranic oxide (converted by washing with water into the oxide, $UO_3,2H_2O$), is precipitated. Alcohol (or ether) accelerates these decompositions, but does not initiate them. In the decomposition of uranyl salts of monobasic aliphatic acids, carbon dioxide and a hydrocarbon result (the formate giving carbon monoxide and dioxide). The other salts examined give rise to carbon dioxide, except the oxalate, which also affords the monoxide. In the case of the glycollate (lactate), formic acid and formaldehyde (acetaldehyde) are first formed. E. E. T.

The Isoelectric Point of *m*-Aminobenzoic Acid and its Equilibrium with Water, Acetic Acid, and Sodium Acetate. J. Barbaudy (*Bull. Soc. chim.*, 1924, [iv], **35**, 31—37).—The equilibria in the systems: (1) *m*-aminobenzoic acid, acetic acid, and water, and (2) *m*-aminobenzoic acid, acetic acid, sodium acetate, and water have been studied at 25°, by determinations of hydrogen ion concentration, density, and viscosity in addition to solubility. From the solubility of *m*-aminobenzoic acid in pure water, the p_H of the isoelectric point for this acid is found to be 3·886. System (1) gave concordance between calculated and found isoelectric points, whilst in system (2) concordance was less good. [Cf. Michaelis and Davidsohn, A., 1911, ii, 192.] E. E. T.

Preparation of Benzyl Diphenylalkylacetates and the Corresponding Acids by Means of Sodamide and Alkyl Iodides. (Mme.) P. Ramart (*Compt. rend.*, 1924, **178**, 396—397; cf. this vol., i, 171).—Benzyl diphenylacetate was dissolved in ether and heated with powdered sodamide for several hours, an alkyl halide then being added and so on. The following new compounds (in addition to some previously known) have been prepared by this method: *Benzyl αα-diphenylpropionate*, prisms, m. p. 71—72°, b. p. 230—233°/10 mm.; *benzyl αα-diphenyl-β-methylbutyrate*, m. p. 73—74°, b. p. 225°/2 mm.; *αα-diphenyl-*Δ^{γ}*-pentenoic* acid, prisms, m. p. 142° (*benzyl* ester, b. p. 240—242°/10 mm.; *amide*, m. p. 90—92°). E. E. T.

The Methods of Preparation of 6-Chloro-3-hydroxybenzoic Acid. V. I. Minaev and K. M. Ripper (*J. Russ. Phys. Chem. Soc.*, 1924, **54**, 673—679).—A further account of work already published (A., 1922, i, 162). G. A. R. K.

β-Phenoxypropionic Acid and some of its Derivatives. Chromanone. S. G. POWELL (*J. Amer. Chem. Soc.*, 1923, **45**, 2708—2711).—In preparing γ-phenoxypropyl alcohol,

$$Ph\cdot O\cdot[CH_2]_2\cdot CH_2OH,$$

(Rindfusz, A., 1919, i, 342), an aqueous solution of sodium phenoxide, in which trimethylenechlorohydrin is completely soluble, may be used in place of an absolute-alcoholic solution; in fact, a slightly better yield (80%) is actually obtained by this method. β-Phenoxypropionic acid, $Ph\cdot O\cdot[CH_2]_2\cdot CO_2H$, may be obtained in yield varying between 32% and 45% by the gradual addition of potassium permanganate solution to a suspension of β-phenoxypropyl alcohol in a solution of magnesium sulphate. Its *ethyl* ester, a colourless oil, has b. p. 170°/40 mm. The acid *chloride*, a liquid of irritating odour, is obtained when the acid is gently warmed for a few seconds with only a slight excess of thionyl chloride; it reacts with aqueous ammonia, giving the *amide*, glistening needles, m. p. 119°. The action of phosphoric oxide in boiling benzene solution on the acid gives *chromanone*,  $C_6H_4<\begin{matrix}O-CH_2\\ \quad\ \mid\\ CO\cdot CH_2\end{matrix}$, a colourless, highly refracting liquid, b. p. 160°/50 mm., with a pleasant, lemon-like odour; it solidifies on keeping to a mass of crystals, m. p. 38·5°. Chromanone is also formed, together with a fraction of b. p. 237°/50 mm. (which is free from halogen), by the prolonged action of an excess of thionyl chloride on β-phenoxypropionic acid. Chromanone forms an *oxime*, glistening needles, m. p. 140°, and a *benzylidene* derivative, long, yellow needles, m. p. 112°. W. S. N.

The Isomeric Esters of *p*-Methoxybenzoylacrylic Acid. G. P. RICE (*J. Amer. Chem. Soc.*, 1924, **46**, 214—223; cf. A., 1923, i, 218).—In continuation of previous work on the isomeric esters of benzoylacrylic acid, the isomeric methyl and ethyl esters of *p*-methoxybenzoylacrylic acid have been examined. The stable yellow forms when exposed to sunlight in benzene solution are converted into colourless isomerides, the reverse change taking place on exposing solutions of the colourless solids, containing a crystal of iodine, to sunlight. *p*-Methoxybenzoylacrylic acid itself is transformed by sunlight to a polymeric acid. The yellow unsaturated esters are much more readily hydrolysed by sodium carbonate than the colourless isomerides, the product being methoxybenzoylacrylic acid. With cold concentrated or boiling dilute hydrochloric acid, both isomeric esters give a mixture of unsaturated acid and α-hydroxy-*p*-methoxybenzoylacrylic acid.

The esters of the *p*-methoxy-acid do not behave in the same way as the esters of the unsubstituted acid on treatment with semicarbazide. *p*-Methoxybenzoylacrylic acid itself yields a semicarbazone; the colourless esters react with semicarbazide to form additive products and semicarbazones of these additive products.

Methyl p-*methoxybenzoylacrylate*, yellow needles, m. p. 71—72°; *colourless isomeride*, needles, m. p. 62°. *Ethyl* p-*methoxybenzoylacrylate*, large, yellow crystals, m. p. 42—43°, b. p. 210—215°/11 mm.; *colourless isomeride*, m. p. 46—47°. *Methyl* αβ-*dibromo-*

p-*methoxybenzoylpropionate* from the yellow ester, m. p. 115°. *Ethyl* αβ-*dibromo*-p-*methoxybenzoylpropionate* from the yellow ester, 1st isomeride, m. p. 51°; 2nd isomeride, m. p. 66°.

Bromination of *p*-methoxybenzoylacrylic acid yielded two isomeric forms of αβ-*dibromo*-p-*methoxybenzoylpropionic acid*, m. p. 140° and 164°, respectively. The *polymeric acid*, $C_{20}H_{20}O_8$, from *p*-methoxybenzoylacrylic acid, has m. p. 180°.

α-*Hydroxy*-p-*methoxybenzoylacrylic acid* (from hydrolysis of unsaturated acid) has m. p. 122°.

The yellow methyl *p*-methoxybenzoylacrylate reacts with 1 mol. of semicarbazide and yields two isomeric *semicarbazones*, yellow needles, m. p. 165°, and colourless plates, m. p. 178°. The same yellow methyl ester on treatment with two molecular proportions of semicarbazide yields the *semicarbazone* of *methyl* α-*semicarbazido*-p-*methoxybenzoylpropionate*, m. p. 178° (decomp.). *Methyl* α-*semicarbazido*-p-*methoxybenzoylpropionate*, m. p. 161—162°, is obtained as a by-product in preparation of the semicarbazone, m. p. 178°, and also by treating the semicarbazone of methyl α-semicarbazido-*p*-methoxybenzoylpropionate with concentrated hydrochloric acid.

Treatment of the solid, m. p. 161°, with nitrous acid gave *methyl nitroso*-α-*semicarbazido*-p-*methoxybenzoylpropionate*, m. p. 132° (decomp.).

In a similar manner, the yellow ethyl ester of *p*-methoxybenzoylacrylic acid yields two isomeric *semicarbazones*, colourless crystals, m. p. 165°, and yellow crystals, m. p. 124°.

The *semicarbazone* of *ethyl* α-*semicarbazido*-p-*methoxybenzoylpropionate*, m. p. 182° (decomp.), and *ethyl* α-*semicarbazido*-p-*methoxybenzoylpropionate*, m. p. 173°, and the *nitroso*-compound, m. p. 124—125° (decomp.), are described.

Methoxybenzoylacrylic acid itself yields a *semicarbazone*, pale yellow solid, m. p. 216° (decomp.). F. A. M.

Constitution of Phthalonic Acid. CORNILLOT (*Compt. rend.*, 1924, **178**, 490—492).—Phthalonic anhydride is rapidly converted by acetic acid at 100° into the acetyl-ψ-phthalonic acid described by Kuroda and Perkin (T., 1923, **123**, 2094), who concluded that phthalonic acid has the phthalide structure. With this conclusion the author disagrees, since the anhydride possesses the normal structure. Acetyl chloride or acetic anhydride converts phthalonic acid into a mixture of phthalonic anhydride and acetyl-ψ-phthalonic acid, the proportions of the two products varying with the conditions of experiment. In boiling ethyl acetate solution (with acetic anhydride) or in suspension in acetyl chloride, almost pure phthalonic anhydride results, whilst the latter, on boiling for an hour with acetic anhydride, is entirely converted into the acetyl-ψ-acid. In any case (as in the work of Kuroda and Perkin), the secondary reaction is responsible for the production of the acetyl-ψ-acid. [See also Tcherniac, T., 1916, **109**, 1236.] E. E. T.

Condensations of Aldehydes with Resorcinol and some other Aromatic Hydroxy Compounds. R. N. SEN and N. N. SINHA (*J. Amer. Chem. Soc.*, 1923, **45**, 2984—2996).—The benzein type of compound has been prepared by condensing aldehydes with resorcinol and similar substances in the presence of concentrated sulphuric acid at 100—130°. The intensity of the fluorescence of alkali solutions of these compounds varies with the number and the position of hydroxyl and carboxyl groups, the influence of hydroxyl groups being greater when they occur in the benzene nuclei associated with the pyrone ring than when they occur in the phenyl residue, whereas the opposite is the case with the carboxyl group. *Resorcinol-1′-hydroxybenzein*, $C_{19}H_{12}O_4$, has m. p. above 260°. Its *tetrabromo*-derivative forms red crystals. *Resorcinol-2′-methoxy-3′-hydroxybenzein*, $C_{20}H_{14}O_5$, is obtained from vanillin and resorcinol as a greyish-black powder, m. p. above 295°. *Gallic acid benzein*, $C_{21}H_{12}O_9$, from gallic acid and benzaldehyde, is a green, microcrystalline powder. *Resorcinolethein*, $C_{14}H_{10}O_3$, from resorcinol and paraldehyde, is a black, microcrystalline powder, m. p. above 290°. *Resorcinolphenetoleazobenzeinsulphonic acid*, $C_{27}H_{20}O_7N_2S$, from phenetoleazobenzaldehydesulphonic acid and resorcinol, does not fluoresce. *Resorcinol*-p-*hydroxybenzein*-m-*carboxylic acid*, $C_{20}H_{12}O_6$, is a yellow powder, m. p. above 295°. β-*Resorcylic acid benzein*, $C_{21}H_{12}O_7$, from β-resorcylic acid and benzaldehyde, is a yellow powder. *Resorcinol-3′-methoxybenzein*, $C_{20}H_{14}O_4$, from anisaldehyde and resorcinol, gives a red *tetrabromo*-derivative, decomposing at 200°. F. G. P.

Reduction Products of some Acids Derived from Camphor. L. PALFRAY (*Ann. Chim.*, 1923, **20**, [ix], 297—385).—A republication of work previously described (A., 1921, i, 418; 1922, i, 548; also Haller and Palfray, A., 1923, i, 577) with additional matter. Reduction of the dimethyl ester of carboxycamphoracetic acid by means of sodium and absolute alcohol resulted in the formation of a mixture of borneol, *camphoracetic glycol*,

$C_8H_{14}<\begin{array}{l}CH\cdot CH_2\cdot CH_2OH\\ |\\ CH\cdot OH\end{array}$,

an oil, b. p. 195—198°/14 mm., α_D^{15} +19° 57′, yielding a *phenylurethane*, colourless spangles, and the *monomethyl* ester,

$$C_8H_{14}<\begin{array}{l}C(CO_2Me)\cdot CH_2\cdot CO_2H\\ |\\ CH\cdot OH\end{array},$$

α_D^{20} +49° 22′. Similar reduction of the diethyl ester also yields borneol, the same glycol, and a substance of the formula $C_{15}H_{23}O_3$, probably a lactone, crystals, m. p. 50—51°, α_D^{14} +62° 22′. A discussion on the molecular refraction of the substances dealt with is appended. The following additional data are given. Ethyl hydrogen camphorate has m. p. 56—56·5°; the diethyl ester of carboxycamphoracetic acid has b. p. 202—204°/18 mm., $d_4^{24\cdot9}$ 1·09635, n_α^{24} 1·47354, n_D^{24} 1·47595, n_β^{24} 1·48708; the dimethyl ester $d_4^{25\cdot1}$ 1·14245, $n_\alpha^{25\cdot1}$ 1·48086, $n_D^{25\cdot1}$ 1·48347, $n_\beta^{25\cdot1}$ 1·49440. To obtain any considerable yield of reduction products from cyanocamphoric and homocamphoric esters, the reaction should be carried out at a temperature approaching 150°. This is also the case with the esters of carboxycamphoracetic acid, but only the ketonic group and the α-carbalkoxy-group are completely hydrogenated, the final product being the glycol. H. J. E.

Derivatives of Camphoronic Acid. W. F. GOEBEL and W. A. NOYES (*J. Amer. Chem. Soc.*, 1923, **45**, 3064—3070).—The investigation was undertaken in order to establish the structure of the various derivatives of camphoronic acid. The attempts to prepare either a dibasic amide or an anhydro-amide which would react with sodium hypobromite failed. Isomeric imide-amides were, however, obtained from the corresponding imides and have been found to react with sodium hypobromite. β-Anhydrocamphoronyl chloride reacts with ammonia to give transparent crystals of an *imide*, $C_9H_{13}O_4N$, m. p. 234·5—235°, $[\alpha]_D^{20}$ −5·40°. A *bromo-imide*, m. p. 220°, is similarly obtained from α-anhydrobromocamphoronyl chloride. *α-Camphoronamide-imide* is obtained by the action of phosphorus pentachloride and then anhydrous ammonia on α-camphoronimide. It forms transparent crystals, m. p. 235—236°, $[\alpha]_{5416}^{28}$ +11·87°. The *acid chloride* of β-camphoronimide is obtained from the imide and phosphorus pentachloride. It is a crystalline solid, m. p. 175·5—176·5° $[\alpha]_{5416}^{26}$ −18·32°. β-*Camphoronimide-amide* obtained by the action of ammonia on the β-imide chloride, is a crystalline solid, m. p. 205°, $[\alpha]_{5416}^{28}$ −13·73°. It reacts readily with sodium hypobromite. Potassium hydroxide fails to open the ring of either α- or β-camphoronimide, partial hydrolysis to the parent acid being the only reaction involved. F. G. P.

Oxidations with Ozone. I. The Preparation of Vanillin. E. BRINER, R. PATRY, and E. DE LUSERNA (*Helv. Chim. Acta*, 1924, **7**, 62—74).—The possibility of utilising ozone for technical oxidations is discussed, and experiments on the oxidation of *iso*eugenol to vanillin are recorded. The oxidations were carried out by conducting a current of ozonised air at varying concentrations of ozone (5% to 19%) into a solution of *iso*eugenol in carbon tetrachloride, at temperatures from −15° to +50°. The highest oxidation efficiency obtained, in terms of ozone consumed, was 20%, at the lowest temperature. At higher temperatures, the efficiency falls off rapidly and the quantity of resinous by-product formed increases. [Cf. *B.*, Apr.] E. H. R.

Phthalaldehyde. II. L. SEEKLES (*Rec. trav. chim.*, 1924, **43**, 93—102; cf. A., 1923, i, 931).—Attempts were made unsuccessfully to utilise the blue colour obtained by the reaction between phthalaldehyde, ammonia, and acetic acid for the determination of small quantities of ammonia. The reaction product appears to contain at least three different coloured substances, and the tint produced varies with the proportions of the reactants.

The dioxime of phthalaldehyde has not hitherto been prepared. It is now obtained in small yield by the action of hydroxylamine on phthalaldehyde in cold alcohol. *Phthalaldioxime* forms light yellow crystals containing $2H_2O$, m. p. 105° (indistinct), decomposing at 150°. The *di*-p-*nitrophenylhydrazone* of phthalaldehyde forms an orange precipitate (α-form), m. p. 244—245° (decomp.). By treatment with gaseous hydrogen chloride in chloroform solution it is converted into a red *isomeride* (β-form), decomposing violently at

208°. Attempts to prepare *iso*quinoline by the interaction of methylamine and phthalaldehyde were not successful. E. H. R.

Amino- and Oximo-derivatives of Thymoquinone. R. M. Hixon (*J. Amer. Chem. Soc.*, 1923, **45**, 2333—2341).—It is pointed out that quinones may be expected to add ammonia (or an amine), (*a*) at the carbonyl group, by analogy with the formation of aldehyde-ammonia, or (*b*) at the ethylenic bond, as do certain unsaturated aliphatic acids, and that actually both reactions probably occur with the quinones. The intermediate additive compound, derived from an amine and a quinone, is structurally analogous to an ammonium salt; this undergoes rearrangement, the amine becoming attached in either of the two ways mentioned. Such an intermediate complex, if formed from a tertiary amine, would be incapable of rearrangement. Actually Jackson and Clarke (A., 1905, i, 908) have reported that dimethylaniline yields coloured additive products with quinones. This is now qualitatively confirmed, since an additive compound appears to be formed when thymoquinone is dissolved in dimethylaniline (2 mols.). This is apparently stable when air and solvents are excluded, but otherwise a purple tar is produced, which, on hydrolysis by means of 50% sulphuric acid, gives both mono- and di-hydroxythymoquinone. This indicates to some extent that tertiary amines may react with quinones just as do primary and secondary amines.

Directions are given for the purification of nitrosothymol and of nitrosocarvacrol. Their benzoates are, in effect, hydrolysed when treated in dry heptane solution with dry methylamine gas. The reaction, which cannot be an ordinary hydrolysis, is explained by assuming the formation of an intermediate compound, structurally similar to aldehyde-ammonia, which undergoes rearrangement to give the nitroso-derivative and *N*-methylbenzamide. These benzoates form unstable *additive* compounds with concentrated nitric acid, having the formulæ and m. p., respectively, $C_{17}H_{17}O_2N,3HNO_3$, 53°, and $C_{17}H_{17}O_2N,2HNO_3$, 65°. Thymoquinone dioxime may be prepared more conveniently by the action of hydroxylamine hydrochloride on nitrosocarvacrol, yield 70%, than by using nitrosothymol, yield 6—10%. It forms a *dibenzoate*, colourless needles, m. p. 199—200° (becomes discoloured at 170°). W. S. N.

The Addition of Mercuric Salts to αβ-Unsaturated Ketones. E. B. Middleton (*J. Amer. Chem. Soc.*, 1923, **45**, 2763—2769).—αβ-Unsaturated ketones such as benzylideneacetophenone (phenyl styryl ketone) react with but one molecule of mercuric acetate, whilst dibenzylideneacetone (distyryl ketone) containing two double linkages reacts with 2 mols. of mercuric acetate. The products obtained in alcoholic solution show that the groups ·OR and $HgOCOCH_3$ have been added. The reactions of the additive compounds show that the mercury compounds of phenyl styryl ketone have the structure Ph·CH(OR)·CH(HgX)·COPh, whilst the derivatives of distyryl ketone are

Ph·CH(OR)·CH(HgX)·CO·CH(HgX)CH(OR)·Ph.

Substitution in the nuclei does not affect the reaction of the unsaturated ketones with mercuric acetate. Ketones of the *cyclo*propane series do not yield additive compounds. A comparison is made between the mercuric acetate additive compounds and the compounds obtained by Vorländer and Eichwald (A., 1923, i, 684), using the mercury halides. *α-Acetoxymercuri-β-methoxy-β-phenylpropiophenone*, $C_{18}H_{18}O_4Hg$, obtained by the action of mercuric acetate on phenyl styryl ketone in methyl alcohol, has m. p. 115°. The corresponding *ethoxy*-derivative has m. p. 134°. *α-Bromomercuri-β-methoxy-β-phenylpropiophenone*, $C_{16}H_{15}O_2BrHg$, m. p. 141°, is prepared by the action of potassium bromide on the acetoxy-compound. The *ethoxy*-compound has m. p. 138°. *α-Bromo-β-methoxy-β-phenylpropiophenone,* m. p. 76°, is obtained by adding bromine to the acetoxymercuric–methoxy-derivative of phenyl styryl ketone. The *ethoxy*-compound has m. p. 60—61° and the corresponding *iodo*-compounds 96° and 75—76°. Sodium methoxide converts α-bromo-β-methoxy-β-phenylpropiophenone into an oil, b. p. 200—205°/6 mm., addition of mercuric acetate to the oil yielding *diacetoxymercuridibenzoylmethane*, $C_{19}H_{16}O_6Hg_2$, m. p. 237°. The bromomethoxyphenylpropiophenone reacts with ethyl magnesium bromide to yield β-phenylvalerophenone, $C_{17}H_{18}O$, m. p. 63°. Distyryl ketone reacts with mercuric acetate to form the dimercurated compound containing two methoxy- and two mercuri-groups, m. p. 183°. *α-Acetoxymercuri-β-methoxy-β-phenyl-p-chloropropiophenone,* m. p. 124°, is obtained from mercuric acetate and *p*-chlorophenyl styryl ketone in methyl alcohol solution. F. G. P.

Preparation of 2 : 4 : 2′ : 4′-Tetrahydroxybenzophenone. J. B. Shoesmith and J. Haldane (*J. Chem. Soc.*, 1924, **125**, 113—115).—2 : 4-Diacetoxybenzonitrile is condensed with resorcinol by means of zinc chloride and dry hydrogen chloride, the resulting imine hydrochloride, $(AcO)_2C_6H_3\cdot C(:NH,HCl)\cdot C_6H_3(OH)_2$, being readily hydrolysed to the required benzophenone in acid solution. A certain amount of resacetophenone and of β-resorcylamide may be recovered from the reaction mixture. 2 : 4-*Diacetoxy-2′ : 4′-dihydroxybenzophenoneimine hydrochloride* gives crystals decomposing at 195°. F. G. P.

The Benzil Rearrangement. V. Cannizzaro's Reaction. A. Lachman (*J. Amer. Chem. Soc.*, 1923, **45**, 2356—2363).—In the Cannizzaro reaction, benzyl benzoate is formed from benzaldehyde, even in the presence of water, provided an excess of alkali is avoided and any considerable rise in temperature is prevented. It is suggested that dihydroxydibenzyl ether, $[CHPh(OH)]_2O$, is formed as an intermediate stage, and by a glycol rearrangement is converted into the benzoate. In the course of the investigation it was shown that by heating benzyl alcohol in a sealed tube at 210—215°, dibenzyl ether is obtained, and that bromine reacts with dibenzyl ether to produce benzyl bromide and benzoyl bromide. F. G. P.

The Isomerism of the Oximes. XV. The Alleged Fourth Benzildioxime. O. L. Brady and F. P. Dunn (*J. Chem. Soc.*, 1924, **125**, 291—296).—The work of Atack and Whinyates (T., 1921, **119**, 1184) has been repeated, but the authors have been unable to confirm the results, no evidence of the existence of the fourth dioxime being obtained. The purely structural theory of the isomerism of the oximes suggested by Atack is criticised and the principal objections to it are stated, particularly the existence of two *O*-ethers. F. G. P.

Dioximes. XVI. G. PONZIO and V. BERNARDI (*Gazzetta*, 1923, **53**, 813—817; cf. this vol., i, 54, 56).—The formation of the two benzildioximes from the two forms of phenylglyoxime by the action of phenyldiazonium chloride (A., 1923, i, 856) proves to be a reaction of general application constituting a new method of synthesising symmetrical and unsymmetrical, disubstituted glyoximes. Not only a glyoxime of the type $NOH{:}CAr{\cdot}CH{:}NOH$, in which Ar is an aryl radical, but also methylglyoxime, reacts with many aryldiazonium chlorides with liberation of nitrogen and formation of the glyoximes, $NOH{:}CR{\cdot}CR_1{:}NOH$. This reaction, which gives a yield of about 45%, is not so simple as is represented by the scheme,

$$NOH{:}CR{\cdot}CH{:}NOH+Ar{\cdot}N_2{\cdot}OH-H_2O \longrightarrow NOH{:}CR{\cdot}C(NOH){\cdot}N_2Ar-N_2 \longrightarrow NOH{:}CR{\cdot}CAr{:}NOH,$$

since there is entire lack of experimental evidence of the formation of an intermediate unstable compound with the N_2Ar group in direct union with a carbon atom. Participation in the reaction of the oximino-groups may, however, be excluded, since these pass with unaltered properties into the final products. Of special interest is the behaviour of methylglyoxime, which yields only the β-forms of glyoximes, $NOH{:}CMe{\cdot}CAr{:}NOH$; the conclusion that it is a β-modification is thus confirmed. Thus, β-phenylmethylglyoxime (A., 1922, i, 17) may be obtained by the action of phenyldiazonium chloride on methylglyoxime in 10% sodium hydroxide solution cooled with ice.

β-o-*Tolylmethylglyoxime*, $NOH{:}CMe{\cdot}C(NOH){\cdot}C_6H_4Me$, prepared from methylglyoxime and *o*-tolyldiazonium chloride, crystallises in white needles, m. p. 236° (slight decomp., and sublimation); its *nickel* salt, $(C_{10}H_{11}O_2N_2)_2Ni$, forms red prisms, m. p. 222°, and its *dibenzoyl* derivative, $C_{24}H_{20}O_4N_2$, prisms, m. p. 144°.

β-*p*-Tolylmethylglyoxime crystallises in white laminæ, m. p. 234—235°; Borsche (A., 1907, i, 326) gave m. p. above 230° (decomp.). Its *nickel* salt, $(C_{10}H_{11}O_2N_2)_2Ni$, forms blood-red prisms, m. p. 250—251° (decomp.), with previous browning, and its *dibenzoyl* compound, white needles, m. p. 148·5—149·5°.

β-*p*-Anisylmethylglyoxime, prepared from *p*-methoxyphenyldiazonium chloride and methylglyoxime, forms white prisms, m. p. 213° (slight decomp.). Boeris (A., 1894, i, 72) gave m. p. 206°, and Tschugaev (A., 1908, i, 554), m. p. 207°; cf. also Wieland (A., 1903, i, 837). Its nickel salt, $C_{20}H_{22}O_6N_4Ni$, crystallises in scarlet needles, m. p. 224° (cf. Tschugaev, *loc. cit.*), and its *dibenzoyl* derivative in needles, m. p. 148·5°.

β-*Phenyl*-p-*tolylglyoxime*, $NOH{:}CPh{\cdot}C(NOH){\cdot}C_6H_4Me$, prepared by the interaction either of *p*-tolyldiazonium chloride and β-phenylglyoxime, or of phenyldiazonium chloride and β-*p*-tolylglyoxime, crystallises in lustrous laminæ, m. p. 223—224° (partial sublimation). Its *nickel* salt, $(C_{15}H_{13}O_2N_2)_2Ni$, forms microscopic, brick-red needles, m. p. 295—297° (decomp.), and its *dibenzoyl* derivative, laminæ, m. p. 184° (slight decomp.).

β-*Phenyl*-p-*anisylglyoxime*, $C_{15}H_{14}O_3N_2$, prepared similarly, crystallises in white laminæ, m. p. 223° (slight decomp.). Its *nickel* salt forms a microcrystalline, blood-red powder, m. p. 264° (decomp.), and its *dibenzoyl* derivative, laminæ, m. p. 162°.

T. H. P.

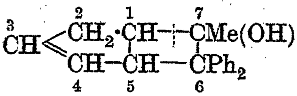
Dioximes. XVIII. L. Avogadro (*Gazzetta*, 1923, **53**, 824—828).—The dehydrogenating action of nitrogen tetroxide on the α-modifications of arylglyoximes proceeds similarly to that of the same reagent on α-phenylglyoxime (A., 1923, i, 1019, 1137). Thus, α-*p*-tolylglyoxime yields a compound which must be regarded as the oxide of *p*-toluoyl cyanide oxime since (1) with acetic anhydride it yields a monoacetyl derivative, (2) it is reduced by means of zinc and acetic acid, giving *p*-toluoyl cyanide oxime, (3) when heated with xylene it undergoes isomerisation to 5-hydroxy-3-*p*-tolyl-1 : 2 : 4-oxadiazole, (4) it unites with a molecule of ammonia to form amino-α-*p*-tolylglyoxime, and (5) it reacts with magnesium methyl iodide to form *p*-tolylmethylglyoxime.

The *oxide* of p-*toluoyl cyanide oxime*,  $NOH{:}C(C_6H_4Me){\cdot}C{<}\begin{smallmatrix}O\\|\\N\end{smallmatrix}$, or $NOH{:}C(C_6H_4Me){\cdot}C{:}N{:}O$, crystallises in silky, white needles, m. p. 108° with previous softening, and is highly stable towards acids, but is readily decomposed by bases or even by boiling water, giving *p*-toluonitrile and substances having the odour of carbylamine. Its *acetyl* derivative forms white prisms, m. p. 157—158°.

Amino-α-p-*tolylglyoxime*, $C_6H_4Me{\cdot}C({:}NOH){\cdot}C({:}NOH){\cdot}NH_2$, crystallises in white laminæ, m. p. 173—174°, and, when treated in aqueous alcoholic solution with nickel acetate, gives a greyish-green precipitate soluble in dilute acetic acid. When boiled with dilute acetic acid it slowly undergoes isomerisation into amino-β-*p*-tolylglyoxime, which has not been investigated further. T. H. P.

Ketens. XLVII. The Constitution of Dimeric Ketens, a Contribution to the Valency Problem of Organic Chemistry. H. Staudinger (*Helv. Chim. Acta*, 1924, 7, 3—8).—A reply to Schroeter (A., 1920, i, 852), who criticises the author's conception of the dimeric ketens as *cyclo*butan-1 : 3-diones or 1 : 3-*cyclo*butenolones, and considers them to be molecular compounds. The conception of dimeric aldoketens as 1 : 3-*cyclo*butenolone derivatives is supported by their physical properties and absorption spectra. Schroeter considers the more stable dimeric ketens to be true *cyclo*butandiones, the less stable to be molecular compounds, but it is pointed out that *cyclo*butane derivatives differ much in their stability to heat; substitution, including the keto-group, weakens the ring, and heavily substituted compounds such as ethyl diethyl*cyclo*butandionedicarboxylate are especially labile. The author's view is also supported by preparation of *cyclo*butane derivatives by the combination of diphenylketen with ethylenic compounds (A., 1920, i, 556, and following abstract). E. H. R.

Ketens. XLVIII. *cyclo*Butane Derivatives from Diphenylketen and Ethylenic Compounds. H. STAUDINGER and A. RHEINER (*Helv. Chim. Acta,* 1924, 7, 8—18).—The compound formed by diphenylketen with styrene is now found to be 1 : 1 : 4-*triphenyl*cyclo*butan-2-one*,  $\begin{array}{l}CHPh\cdot CPh_2\\ CH_2—CO\end{array}$, instead of the 1 : 1 : 3-compound as previously stated (Staudinger and Suter, A., 1920, i, 556). It follows that the acid obtained by treating it with sodium hydroxide in alcoholic solution is αα*β-triphenyl*-n-*butyric acid* instead of the ααγ-compound. Evidence for the constitution of the triphenyl*cyclo*butanone was obtained through the action of methyl magnesium iodide, by means of which the tertiary alcohol, 1-*methyl*-2 : 2 : 3-*triphenyl*cyclo*butan*-1-*ol* was obtained, colourless crystals, m. p. 132°; the yield was 87% of the theoretical. When rapidly distilled at the ordinary pressure, the tertiary alcohol decomposes to the extent of 80% into *as*-diphenylacetone and styrene and 20% into acetone and triphenylethylene. These products establish its constitution. When distillation is carried out in a high vacuum, decomposition does not take place, but an *isomeride* is formed, m. p. 137°; in all probability the ring has opened with formation of a triphenyl-*n*-propyl methyl ketone. By the action of phenyl magnesium bromide on the triphenyl*cyclo*butanone there is obtained, not the expected tertiary alcohol, but *benzylidenediphenylacetone*, $CHPh_2\cdot CO\cdot CH:CHPh$ [*benzhydryl styryl ketone*], m. p. 112°, b. p. 250°/18 mm. The same compound was synthesised from diphenylacetone and benzaldehyde (cf. Rack, A., 1923, i, 681).



$\overset{3}{CH}<\begin{array}{l}\overset{2}{CH_2}\cdot\overset{1}{CH}-\vdots-\overset{7}{C}Me(OH)\\ \underset{4}{CH}-\underset{5}{CH}—\underset{6}{C}Ph_2\end{array}$

As previously described (*loc. cit.*), diphenylketen combines with *cyclo*pentadiene to form a compound, which can be reduced to a saturated compound, for which the formula  $CH_2<\begin{array}{l}CH_2\cdot CH-\vdots-CO\\ CH_2\cdot CH—CPh_2\end{array}$, is now proposed. When this is submitted to prolonged boiling with sodium hydroxide, hydrolysis takes place at the dotted line with formation of *diphenyl*cyclo*pentylacetic acid*, m. p. 85°; *anilide*, m. p. 139°. The compound of diphenylketen with *cyclo*pentadiene reacts with methyl magnesium iodide to give the tertiary alcohol having the annexed formula, designated 6 : 6-*diphenyl*-7-*methyl*-0 : 2 : 3-bicyclo-3 : 4(?)-*hepten*-7-*ol*, m. p. 130°. When boiled with alcoholic potassium hydroxide the heptane ring opens, probably at the dotted line, forming a *ketone*; its semicarbazone has m. p. 115°. By treatment with hydrogen and platinum black, the above heptenol is reduced to the corresponding *heptanol*, m. p. 99°. By the action of phenyl magnesium iodide on the diphenylketen–*cyclo*pentadiene compound, a *substance* was obtained, m. p. 214°, having the same empirical composition as the original compound. It may be a dimeride. Diphenylketen and di*cyclo*pentadiene form a *compound*, m. p. 95°. E. H. R.

Ketens. XLIX. *cyclo*Butane Derivatives from Dimethylketen and Ethylenic Compounds. H. STAUDINGER and P. J. MEYER (*Helv. Chim. Acta*, 1924, **7**, 19—22).—Dimethylketen combines less readily with ethylenic compounds than diphenylketen, but the compounds when formed are more stable than those from diphenylketen. The four-membered ring is relatively stable and the ketonic group has normal properties. Dimethylketen does not combine with styrene, but with vinyl ethyl ether it forms 3(or 4)-*ethoxy*-1 : 1-*dimethyl*cyclo*butan*-2-*one*, a colourless oil, b. p. 166—169°; the *phenylhydrazone* forms white needles, m. p. 70°, and quickly decomposes in the air. With *cyclo*pentadiene, dimethylketen forms a *compound* probably having the formula $CH{<}^{CH_2\cdot CH\cdot CO}_{CH{-}{-}CH\cdot CMe_2}$, but the position of the double bond is uncertain; it is an oil with a camphor-like odour, b. p. 175—178°; when superheated it decomposes into dimethylketen and *cyclo*pentadiene. Its *semicarbazone* has m. p. 215°. When reduced with hydrogen and platinum black it gives the saturated compound, 6 : 6-*dimethyl*-0 : 2 : 3-bicyclo*heptan*-7-*one*, also having the odour of camphor, b. p. 176—178°; it gives dimethylketen when superheated. Its *semicarbazone* has m. p. 224°. E. H. R.

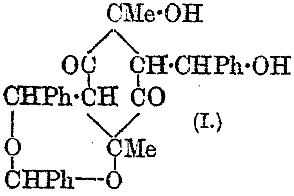
Reaction Products from Aldehydes and 1 : 2-Diketones. O. DIELS [with R. W. POINDEXTER, K. ILBERG, and W. GÄDKE] (*Annalen*, 1923, **434**, 1—20).—When a mixture of benzaldehyde and diacetyl is treated at − 10° with 25% methyl-alcoholic potassium hydroxide solution, the diketone first polymerises to its dimeride, 1 : 4-dihydroxy-1 : 4-dimethyl*cyclo*hexan-3 : 6-dione (Diels, Blanchard, and v. d. Heyden, A., 1914, i, 1052); this then undergoes condensation with the aldehyde (3 mols.), 1 mol. of water being eliminated, with the formation of the same *compound* (I), slender, white needles, m. p. 198° (decomp.), which is obtained if the dimeride itself is used. The structure of this substance is evident from the following reactions. Although, probably owing to steric hindrance, the ketone groups are not reactive, the hydroxyl group next to the phenyl radical can be esterified. The *benzoate* forms thick, transparent prisms, m. p. 192°; the *acetate*, four-sided tablets or prisms, has m. p. 197—198°. But if, in preparing the acetate, the action of acetic anhydride is continued, water is eliminated, with the production of the unsaturated *acetate*, $-OC\cdot CMe{:}C(CHPh\cdot OAc)\cdot CO-$, m. p. 237°. This compound reacts immediately with potassium permanganate in glacial acetic acid solution, or with bromine in cold chloroform solution; the subsequent spontaneous elimination of hydrogen bromide from the dibromide produced in the latter reaction gives two *bromo*-derivatives, $C_{31}H_{27}O_6Br$, (*a*) colourless needles, or



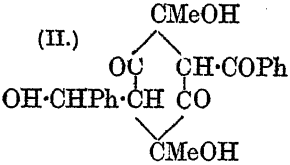
(I.)

small, elongated plates, m. p. 193°, (*b*) small, transparent prisms, m. p. 210°. The action of phenylhydrazine in methyl-alcoholic glacial acetic acid solution at 65° on the unsaturated acetate gives the corresponding unsaturated *alcohol*, m. p. 198—203°, $+x\mathrm{EtOH}$, long prisms, which is readily converted into the compound (I) by boiling with hydrochloric, acetic, or propionic acid, and gives the saturated *methyl* ether, $-\mathrm{OC{\cdot}CMe(OMe){\cdot}CH(CHPh{\cdot}OH){\cdot}CO}-$ (felted needles, m. p. 240°, after decomposing at 218°), when boiled with methyl alcohol containing a trace of hydrochloric acid. Similarly, the action of acids on the unsaturated acetate gives the saturated acetate, which, like the analogous benzoate, is readily hydrolysed to the compound (I) by means of boiling alcoholic potassium hydroxide solution. By the action of a boiling mixture of glacial acetic acid and concentrated nitric acid on the compound (I), the secondary alcohol group is oxidised to a ketone group,

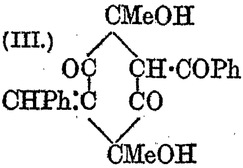
$$-\mathrm{CO{\cdot}CMe(OH){\cdot}CH(COPh){\cdot}CO}-,$$

with the formation of a *compound*, m. p. 203—204° (decomp.), which crystallises from acetonitrile with 1MeCN, in rhombic crystals, readily soluble in alkali. In 25% methyl-alcoholic potassium hydroxide solution, benzaldehyde is rapidly eliminated, with the production of the *compound* (II), thin, felted needles, m. p. 151—153° after sintering at about 146°. The latter is soluble in aqueous alkali, but soon resinifies, more rapidly on warming, with the elimination of benzaldehyde. It is converted by the action of methyl alcohol containing hydrogen chloride into its *methyl* ether, compact, snow-white crystals, m. p. 169—171° (slight decomp.); methyl hydrazinecarboxylate gives a *salt*, felted needles, m. p. 130—132° (decomp.), in the formation of which, presumably, the benzoyl group has taken part in its enolic form. The ketonic groups are not reactive. The compound (II) forms an additive *compound* with cold formic acid, but the boiling, anhydrous reagent causes the elimination of water, to give 2-*benzoyl*-1 : 4-*dihydroxy*-5-*benzylidene*-1 : 4-*dimethyl*cyclo*hexan*-3 : 6-*dione* (III), a bright sulphur-yellow compound, m. p. 238—243°, one of the ketone groups of which is reactive; the *oxime*, m. p. 221—222°, *semicarbazone*, long, colourless needles, decomp. about 235°, m. p. 245—248°, and the *carbomethoxyhydrazone*, long, colourless prisms, decomp. 220°, m. p. 240—243°, are described. The compound (III) is decomposed at 250—270° into benzoyldiacetyl and benzylidenediacetyl.

(II.)



(III.)



Compounds are also prepared by condensing diacetyl with furfurol and anisaldehyde. The first forms thick, colourless needles, m. p. 203° (decomp.) after sintering at 180°; the second forms small needles, and has m. p. 203—205° (decomp.). With concentrated sulphuric acid they give, respectively, a dark reddish-purple coloration, which changes to brown, and an intense carmine coloration, which persists during twenty-four hours. W. S. N.

Trihydroxymethylanthraquinones. I. G. D. GRAVES and R. ADAMS (*J. Amer. Chem. Soc.*, 1923, **45**, 2439—2455).—3 : 6-Dimethoxyphthalic anhydride is prepared by the action of boiling 98% sulphuric acid on the dimethyl ether of 2 : 3-dicyanoquinol, which is obtained by the action of potassium hydroxide solution and methyl sulphate on 2 : 3-dicyanoquinol.

The action of an excess of *p*-cresol on 3 : 6-dimethoxyphthalic anhydride in the presence of aluminium chloride at 70° gives 3 : 6-*dimethoxy*-2-(2′-*hydroxy*-5′-*methylbenzoyl*)*benzoic acid*, white plates, m. p. 218° (corr.), together with 12 : 15-*dimethoxy*-2 : 7-*dimethylfluoran*, white crystals, m. p. 290° (corr.). When the benzoic acid derivative is boiled with potassium hydroxide solution and methyl sulphate, the product is 3 : 6-*dimethoxy*-2-(2′-*methoxy*-5′-*methylbenzoyl*)*benzoic acid*, white needles, or colourless, truncated prisms, m. p. 203—204° (corr.), which is identical with the product from 3 : 6-dimethoxyphthalic anhydride and *p*-cresyl methyl ether (cf. following abstract). When the substituted benzoic acid and concentrated sulphuric acid are heated at 100° with a small quantity of boric acid, the colour changes from green to bluish-red, owing to the formation of 1-*hydroxy*-5 : 8-*dimethoxy*-4-*methylanthraquinone*, red needles, m. p. 224° (corr.). The latter is demethylated by boiling with glacial acetic acid and hydrobromic acid (constant-boiling), giving 1 : 5 : 8-*trihydroxy*-4-*methylanthraquinone*. When 3 : 6-dimethoxyphthalic anhydride is heated at 75° with an excess of *o*-cresol in the presence of aluminium chloride, the products are 3 : 6-*dimethoxy*-2-(2′-*hydroxy*-3′-*methylbenzoyl*)*benzoic acid*, white needles, m. p. 194° (corr.), and o-*cresol*-3 : 6-*dimethoxyphthalein*, white needles, m. p. 258° (corr.). The latter is an indicator, changing from colourless to red at p_H 9·1. The methylation of the benzoic acid gives 3 : 6-*dimethoxy*-2-(2′-*methoxy*-3′-*methylbenzoyl*)-*benzoic acid*, white needles, m. p. 178° (corr.), which is not identical with the acid formed by condensing 3 : 6-dimethoxyphthalic anhydride with *o*-cresyl methyl ether; in the latter reaction, there is also formed the *dimethyl ether* of *o*-cresol-3 : 6-dimethoxyphthalein, white needles, m. p. 202° (corr.), which is likewise produced by the methylation of the phthalein. The action of sulphuric acid, containing boric acid, on the benzoic acid derivative, gives 1-*hydroxy*-5 : 8-*dimethoxy*-2-*methylanthraquinone*, red needles, m. p. 165° (corr.), which may be demethylated to give 1 : 5 : 8-*trihydroxy*-2-*methylanthraquinone*, red needles, which sublime at 250—260°. When *o*-cresol-3 : 6-dimethoxyphthalein and 3 : 6-dimethoxyphthalic anhydride are heated at 125° with concentrated sulphuric acid, the product is 2 : 5 : 8-*trihydroxy*-1-*methylanthraquinone*, dark red needles, m. p. 270° (corr.), which is identical with the product obtained by condensing 3 : 6-dimethoxyphthalic anhydride with *o*-cresyl methyl ether, dehydrating the benzoylbenzoic acid thus obtained, and hydrolysing the resulting anthraquinone. The interaction of 3 : 6-dimethoxyphthalic anhydride and *m*-cresol at

75° in the presence of aluminium chloride gives 3 : 6-*dimethoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid*, white needles, m. p. 233° (corr.), and 3-*hydroxy-6-methoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid*, white needles, m. p. 189° (corr.). A third substance formed in the above reaction is m-*cresol-3 : 6-dimethoxyphthalein*, white needles, m. p. 271° (corr.), a solution of which changes from colourless to red at p_H 9·8. The conversion of 3 : 6-dimethoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid into 1-*hydroxy-5 : 8-dimethoxy-3-methylanthraquinone*, red needles, m. p. 172° (corr.), can only be accomplished by the use of fuming sulphuric acid at 100° in the presence of boric acid. The demethylation of this dimethoxyanthraquinone by means of glacial acetic acid and hydrobromic acid gives 1 : 5 : 8-*trihydroxy-3-methylanthraquinone*, red needles, m. p. 227° (corr.).

The condensation of 3 : 5-dimethoxyphthalic anhydride with *m*-cresol by heating with aluminium chloride at 70° gives 3 : 5-*dimethoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid*, white needles, m. p. 233° (corr.), and m-*cresol-3 : 5-dimethoxyphthalein*, which cannot be purified. The former gives, on methylation, 3 : 5-*dimethoxy-2-(2′-methoxy-4′-methylbenzoyl)benzoic acid*, white needles, m. p. 219° (corr.), whereas the condensation of 3 : 5-dimethoxyphthalic anhydride with *m*-cresyl methyl ether gives 3 : 5-*dimethoxy-2-(4′-methoxy-2′-methylbenzoyl)benzoic acid*, m. p. 233° (corr.). The action of fuming sulphuric acid and boric acid at 100° on 3 : 5-dimethoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid leads to sulphonation, a poor yield of the expected *anthraquinone*, yellow needles, m. p. about 185°, being obtained. This substance gives a red solution in alkali, which reacts with methyl sulphate at 100° to give a *trimethoxy* compound, yellow needles, m. p. about 175—180°, which gives a red solution in concentrated sulphuric acid, and should be the trimethyl ether of emodin, if the latter has the structure suggested (*Arch. Pharm.*, 1912, **250**, 301). The action of concentrated nitric acid in glacial acetic acid solution at 50—60° on 3 : 5-dimethoxy-2-(2′-hydroxy-4′-methylbenzoyl)benzoic acid gives the 5′-*nitro*-derivative, pale yellow needles, m. p. 241° (corr.), but the product of the condensation of 3 : 5-dimethoxyphthalic anhydride and *o*-nitro-*m*-cresol is 3 : 5-*dimethoxy-2-(4′-hydroxy-5′-nitro-2′-methylbenzoyl)benzoic acid*, white needles, m. p. 181° (corr.).

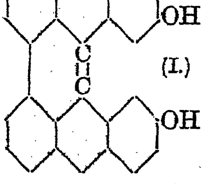
3 : 5-Dimethoxyphthalic acid is obtained by the action of cold, alkaline, potassium permanganate solution on 3 : 5-dimethoxyphthalide, which is prepared by heating its carboxylic acid. The latter is made by the action of warm sodium hydroxide solution on 3 : 5-dimethoxytrichloromethylphthalide, which is formed when a mixture of chloral hydrate and ethyl 3 : 5-dimethoxybenzoate is treated with somewhat concentrated sulphuric acid. W. S. N.

Trihydroxymethylanthraquinones. II. J. H. GARDNER and R. ADAMS (*J. Amer. Chem. Soc.*, 1923, **45**, 2455—2462; cf. preceding abstract).—The action of an excess of *p*-cresyl methyl ether on 3 : 6-dimethoxyphthalic anhydride at 70° in the presence of aluminium chloride gives 3 : 6-dimethoxy-2-(2′-methoxy-5′-methylbenzoyl)benzoic acid, together with the *dimethyl ether* of *p*-cresol-3 : 6-dimethoxyphthalein, colourless needles, m. p. 187·5° (corr.). When the trimethoxybenzoic acid is rapidly heated with concentrated sulphuric acid at 150°, and then cooled, the products are 1-hydroxy-5 : 8-dimethoxy-4-methylanthraquinone and 1 : 5 : 8-*trihydroxy-4-methylanthraquinone*, slender, red needles, m. p. 276—278° (corr.) (with sublimation); the latter is the sole product if the reaction mixture is kept at 145—155° for twenty minutes. When a mixture of 3 : 6-dimethoxyphthalic anhydride and an excess of *o*-cresyl methyl ether is treated at 65° with aluminium chloride, there are formed 3 : 6-*dimethoxy-2-(4′-methoxy-5′-methylbenzoyl)benzoic acid*, a white powder, m. p. 192° (corr.), and the *dimethyl ether* of *o*-cresol-3 : 6-dimethoxyphthalein, colourless needles, m. p. 202—203° (corr.). When the acid is rapidly heated with concentrated sulphuric acid at 150°, and immediately cooled, the chief product is 5 : 8-*dihydroxy-2-methoxy-1-methylanthraquinone*, dark red needles, m. p. 249—249·5° (corr.), which is accompanied by a small quantity of 2 : 5 : 8-trihydroxy-1-methylanthraquinone. The latter may more conveniently be prepared by heating a mixture of concentrated sulphuric acid, 3 : 6-dimethoxyphthalic anhydride, and *o*-cresol-3 : 6-dimethoxyphthalein, or its dimethyl ether, at 125°. The structure of the original benzoic acid is proved by distilling the trihydroxyanthraquinone with zinc dust, the resulting methylanthracene being then oxidised to 1-methylanthraquinone. 3-*Hydroxy-6-methoxy-2-(4′-methoxy-1′-methylbenzoyl)benzoic acid*, colourless prisms, m. p. 194—195° (corr.), and not the dimethoxy-acid, is obtained when 3 : 6-dimethoxyphthalic anhydride is treated with an excess of *m*-cresyl methyl ether and aluminium chloride at 75°; a phthalein is not produced. A pure derivative of anthraquinone has not been obtained by the dehydration of this acid.

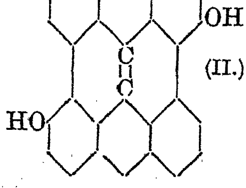
W. S. N.

Reduction Products of the Hydroxyanthraquinones. IV.

J. W. E. Haller and A. G. Perkin (*J. Chem. Soc.*, 1924, **125**, 231—239).—Reduction of 2-hydroxyanthraquinone with glucose and alkali in the presence of sodium nitrate yields 2-hydroxybenzanthronecarboxylic acid, and two compounds which are now shown to be 3 : 6′-dihydroxyhelianthrone, $C_{28}H_{14}O_4$ (I), and 3 : 6′-dihydroxy-*meso*naphthadianthrone, $C_{28}H_{12}O_4$ (II). Better yields of (I) are obtained by the oxidation of dihydroxydianthrone with potassium ferricyanide. (II) may be obtained by exposing the diacetyl derivative of (I) (in benzene or acetic acid solution) to sunlight for some weeks, when an almost quantitative yield of the diacetoxynaphthadianthrone



(I.)



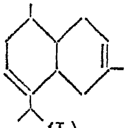
(II.)

results. Oxidation of the acetyl compound of (I) with chromic acid yields *diacetoxy*-1 : 1′-*dianthraquinonyl*, $C_{28}H_{12}O_6Ac_2$, small plates, m. p. 277°. The corresponding *dihydroxy* compound crystallises in prisms or leaflets, m. p. >350°. The *dimethyl ether*, $C_{30}H_{18}O_6$, crystallises in yellow prisms, m. p. 343—344°. With iodine in pyridine solution, (I) yields 5-*iodo*-3 : 6′-*diacetoxyhelianthrone*, $C_{32}H_{17}O_6I$, yellow needles, m. p. 282°, and from this by hydrolysis the *dihydroxy* compound is obtained in the form of scarlet needles, m. p. >350°. 3 : 6′-*Dihydroxynaphthadianthrone*, $C_{28}H_{12}O_4$, is an orange-brown powder, m. p. >350°. Its *diacetyl* derivative crystallises in yellow needles. F. G. P.

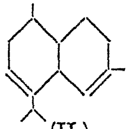
Camphorylcarbamates and their Physiological Action. H. E. Fierz-David and W. Müller (*J. Chem. Soc.*, 1924, **125**, 26—27).—Camphorylcarbamates may be obtained in almost quantitative yield by the interaction of aminocamphor and alkyl chloroformates. Their pronounced poisonous action renders them unsuitable for practical application. iso*Amyl* and *allyl camphorylcarbamates* are viscous, oily liquids, b. p. 199°/11 mm., and 186°/10 mm., respectively, with $[\alpha]_D$ +34·2°, +34·3°. *Methyl camphorylcarbamate*, m. p. 110°, b. p. 169°/11 mm., $[\alpha]_D$ +39·4°. The *ethyl*, iso*propyl*, and iso*butyl* derivatives have, respectively, m. p. 88°, 73°, 83°; b. p. 178°/13 mm., 170°/10 mm., 184°/11 mm., with $[\alpha]_D$ +35·1°, 35·3°, and 33·9°. F. G. P.

Piperitone. VII. The Constitution of Piperitone. J. Read, H. G. Smith, and R. S. Hughesdon (*J. Chem. Soc.*, 1924, **125**, 129—137).—Benzyl-*dl*-*iso*menthone, obtained by hydrogenation of benzylidene-*dl*-piperitone, is distinct from 2-benzyl-*dl*-*iso*menthone obtained, from *dl*-piperitone. It is concluded from this observation that piperitone is Δ^1-*p*-menthen-3-one, and benzylidenepiperitone is 6-benzylidene-Δ^1-*p*-menthen-3-one. 6-Benzyl-*dl*-*iso*menthone reacts with benzaldehyde to yield 2-benzylidene-6-benzyl-*dl*-*iso*menthone, and it also forms a semicarbazone, whilst 2-benzyl-*dl*-*iso*menthone is incapable of so reacting. 2-*Benzylidene*-dl-iso*menthone hydrochloride* forms colourless needles, m. p. 108—110°. 2-*Benzyl*-dl-iso*menthol*, $C_{10}H_{19}O{\cdot}CH_2Ph$, is a colourless, viscid liquid, b. p. 194—196°/20 mm. Its *phenylurethane* melts at 153—154°. 2-*Benzylidene*-dl-iso*menthone*, $C_{10}H_{16}O{:}CHPh$, is a colourless liquid, b. p. 193—195°/15 mm. The corresponding *benzyl* compound, $C_{10}H_{17}O{\cdot}CH_2Ph$, is a colourless, viscid liquid, b. p. 195—197°/20 mm., d_4^{20} 0·9957, n_D^{20} 1·5230, and $[R_L]_D$ 74·92. 6-*Benzyl*-dl-iso*menthone*, $C_{10}H_{17}O{\cdot}CH_2Ph$, is a colourless, viscid liquid, b. p. 202—203°/14 mm., d_4^{20} 0·9884, n_D^{20} 1·5176, and $[R_L]_D$ 74·84. Its *semicarbazone* crystallises in colourless prisms, m. p. 170—171°. 6-Benzyl-*dl*-*iso*menthone distils at 213—220°/20 mm., and has d_4^{20} 0·9905, n_D^{20} 1·5239, and $[R_L]_D$ 75·42. Its *semicarbazone* has m. p. 170—171°. 6-*Benzyl*-2-*benzylidene*-dl-iso*menthone* is a yellow, mobile oil, b. p. 218—225°/15 mm. Reduction of this yields 2 : 6-*dibenzyl*-dl-iso*menthol*, a pale yellow, viscid liquid, b. p. 282—287°/23 mm. 6-*Benzyl*-dl-iso*menthol*, $C_{10}H_{19}O{\cdot}CH_2Ph$, distils at 203—207°/16 mm. Its *phenylurethane* crystallises in needles and has m. p. 138—139°. A crystalline variety of the *iso*menthol, m. p. 66—68°, has also been obtained. F. G. P.

Higher Terpene Compounds. XVIII. The Constitution of Cadinene. L. Ruzicka and M. Stoll (*Helv. Chim. Acta*, 1924, 7, 84—94).—The carbon framework of cadinene has already been established by its dehydrogenation with sulphur to cadaline (Ruzicka and Meyer, A., 1921, i, 573). This result has now been confirmed by the catalytic dehydrogenation of cadinene with platinum black in a high vacuum at 300°. It remains therefore to determine the positions of the two double bonds. That one of these is probably adjacent to the *iso*propyl group has already been shown (Ruzicka and Seidel, A., 1922, i, 562). It is now shown, by a variety of arguments, that cadinene is probably to be represented by one or both of the two annexed formulæ.

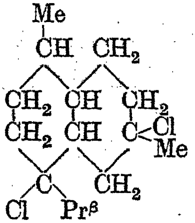


(I.)

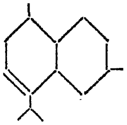


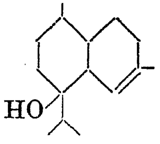
(II.)

The products obtained by the action of ozone on cadinene, followed by decomposition of the ozonide first formed, render it extremely improbable that both double bonds are contained in the same ring. Although great difficulty was experienced in obtaining any identifiable products from this reaction, an *ethyl dicarboxylate* was obtained, b. p. 190—200°/0·2 mm., having the composition $C_{19}H_{30}O_5$ or $C_{19}H_{32}O_6$, in which all the carbon atoms of cadinene are intact. The absence of conjugated double bonds in cadinene is shown by the failure of attempts at reduction with sodium and amyl alcohol. The oxidation of cadinene with manganese dioxide and sulphuric acid as described by Ruzicka, Schinz, and Meyer (this vol., i, 171) resulted in the formation of trimellitic acid and mellophanic acid as primary products, and benzenepentacarboxylic acid as a secondary product. Cadinene dihydrochloride can be definitely stated to have the annexed formula. E. H. R.

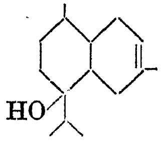


Higher Terpene Compounds. XIX. Cadinol from Galbanum Oil. L. Ruzicka and M. Stoll (*Helv. Chim. Acta*, 1924, 7, 94—105).—A sesquiterpene alcohol, cadinol, $C_{15}H_{26}O$, which by loss of a molecule of water gives cadinene, was discovered by Semmler and Jonas in galbanum resin (A., 1915, i, 573). Having elucidated the constitution of cadinene (preceding abstract), the authors now attempt to discover that of cadinol. The compound does not react at a high temperature with phthalic anhydride, and must therefore be a tertiary alcohol. To determine the position of the double bond and of the hydroxyl group, the action of ozone was studied on cadinol itself and on the dihydrocadinene obtained by hydrogenating cadinol and then removing water. An attempt to reduce cadinol to a dihydrocadinene by heating with zinc dust was unsuccessful; only cadinene was obtained, by dehydration of the cadinol. Reduction of cadinol to *dihydrocadinol* was effected with some difficulty by hydrogen and platinum black; it is a colourless oil, b. p. 150—153°/12 mm., $[\alpha]_D$ +23°, n_D^{16} 1·4948, d_4^{16} 0·9579. By boiling with 90% formic acid, dihydrocadinol is converted into *dihydrocadinene* (annexed formula), a colourless oil, b. p. 129—131°/12 mm., $[\alpha]_D$ +19·8°, n_D^{13} 1·4952, d_4^{13} 0·8999. By the action of ozone on this compound and decomposition of the ozonide there were obtained a keto-aldehyde and a keto-acid by the disruption of the hydrocarbon at the double bond; neither, however, was obtained in a pure condition. By ozonisation of cadinol itself there was obtained a neutral product, $C_{15}H_{24}O_2$, probably a *ketone–alcohol*, b. p. 180—184°/12 mm.; it contains one double bond. In addition a doubly unsaturated *ketone*, $C_{15}H_{22}O$, probably formed from the previous compound by loss of water, was obtained, b. p. 140—145°/12 mm. Oxidation of this ketone with manganese dioxide and sulphuric acid gave only mellophanic acid. The higher-boiling fractions of the neutral products from the ozonisation of cadinol gave, besides mellophanic acid, trimellitic acid. These observations can be explained on the assumption that cadinol consists of at least two forms, α and β, with probably a small proportion of a third form, γ, having the formulæ :

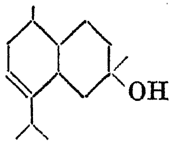




α-Cadinol.



β-Cadinol.



γ-Cadinol.

Structural formulæ are suggested for the products obtained by the ozonisation of cadinol, based on the above formulæ for cadinol. The cause of the formation of trimellitic acid by oxidation of higher fractions of these products is traced back to the small proportion of γ-cadinol probably present in the cadinol. E. H. R.

The Chlorohydrins of β-Pinene. G. G. HENDERSON and C. A. KERR (*J. Chem. Soc.*, 1924, **125**, 102—106).—β-Pinene, on treatment with a very dilute aqueous solution of hypochlorous acid, gives mainly a mixture of three isomeric crystalline *dichlorohydrins*, $C_{10}H_{18}O_2Cl_2$, of m. p. 135°, 166°, and 131°, respectively. They are isomeric but not identical with the corresponding compounds prepared from α-pinene. The dichlorohydrin of m. p. 135° is converted into a *monochlorohydrin*, $C_{10}H_{17}O_2Cl$, m. p. 128—129°, by the action of dilute potassium hydroxide solution; this is an isomeride of pinol glycol chlorohydrin. Further action of caustic alkali converts it into an oily liquid which is apparently somewhat similar to pinol oxide in properties. The dichlorohydrin, m. p. 166°, also yields an oily liquid on treatment with caustic alkali, but a solid monochlorohydrin could not be obtained in this case. The third dichlorohydrin, m. p. 131°, is unaffected by caustic alkali in the cold. F. G. P.

Some Oxidation Products of β-Pinene. G. G. HENDERSON and D. CHISHOLM (*J. Chem. Soc.*, 1924, **125**, 107—113).—β-Pinene unites with chromyl chloride to form a solid *compound*, $C_{10}H_{16}\cdot 2CrO_2Cl_2$, which on decomposition by water yields as chief product the ketone $C_9H_{14}O$, previously prepared in a similar fashion from α-pinene. A trace of an aldehyde and a small quantity of the inactive form of *trans*-pinol glycol were also obtained. Oxidation of β-pinene in glacial acetic acid solution by hydrogen peroxide gives a mixture of volatile and non-volatile products, the chief constituents of the volatile portion being borneol and a little fenchyl alcohol. The non-volatile portion could not be obtained sufficiently pure for identification. F. G. P.

Diacetyl Compound of Desmotropo-Artemisin. P. BERTOLO (*Gazzetta*, 1923, **53**, 867—869).—It is now found that desmotropo-artemisin forms a diacetyl derivative, so that, in the transformation of artemisin into desmotropo-artemisin, the fourth oxygen atom retains its alcoholic character (cf. A., 1923, i, 1108).

Diacetyldesmotropo-artemisin, $C_{19}H_{22}O_6$, crystallises in hard, lustrous, white needles, often grouped in radiating masses, m. p. 149—150°, $[\alpha]_D^{25}$ −50·75° (in alcohol). When hydrolysed by means of alcoholic potassium hydroxide, it yields, not artemisin, but a moderately stable, acid compound, m. p. above 200°, which is apparently identical with that obtained by hydrolysis of the acetyl derivative of artemisin (*loc. cit.*). T. H. P.

The Formation of Free Radicals by Reduction with Vanadous Chloride. J. B. CONANT and A. W. SLOAN (*J. Amer. Chem. Soc.*, 1923, **45**, 2466—2472).—The addition of vanadous chloride solution to a solution of triphenylpyrylium chloride, or of its ferric chloride double salt, in the absence of air, causes the formation of a red precipitate, which is thought to be a *free radical.* With chloroform or benzene, it gives a red solution, the colour of which disappears when it is shaken with air. The substance is reoxidised to the pyrylium salt when it is treated in aqueous suspension with a solution of a ferric salt; if this process is conducted in the absence of oxygen, using freshly prepared material, a maximum of 1 mol. of ferric salt is required, but much less than this is needed if the compound, which is evidently unstable, has been kept for a few hours, even in an atmosphere of carbon dioxide.

The action of an excess of vanadous chloride on 9-phenylxanthylium chloride, in hydrochloric acid solution, in the absence of air, gives Gomberg and Cone's free radical, phenylxanthyl, which is identified by conversion into its peroxide.

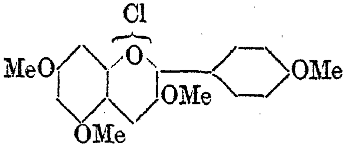
Triphenylcarbinol, in concentrated hydrochloric acid or concentrated sulphuric acid solution, is reduced by means of vanadous chloride in an atmosphere of carbon dioxide to triphenylmethyl, which is likewise identified by means of the peroxide.

The action of vanadous chloride on a very dilute solution of xanthylium chloride in concentrated hydrochloric acid gives a pink solid, which may be kept for a few hours in air at the ordinary temperature, but gradually changes to the colourless dixanthyl. Attempts to dry it in an atmosphere of nitrogen without loss of colour have been unsuccessful. When the bright pink solid is washed with water, drained, and dissolved in chloroform in an atmosphere of nitrogen, the solution is momentarily red; this colour disappears in the course of a few seconds. It is evident, from the last experiment, that polymerisation, and not oxidation, causes the change to dixanthyl. There is therefore strong evidence that the pink solid is the free radical, *xanthyl*.

The addition of vanadous chloride to an aqueous solution of benzylpyridinium chloride does not cause the formation of a precipitate, although the first portions of vanadous chloride undergo a change of colour; after making the solution alkaline, however, *N* : *N'*-dibenzyltetrahydrodipyridyl may be extracted from the solution by means of ether. W. S. N.

Chloro- and Amino-anthracoumarins. V. I. MINAEV (*J. Russ. Phys. Chem. Soc.*, 1924, **54**, 680—684).—A short abstract of this work has already appeared (A., 1922, i, 162); the preparation of the following additional compounds is now described: 8-*amino-anthracoumarin*, from *m*-aminocinnamic and *m*-hydroxybenzoic acid, silvery crystals resembling β-naphthol, softens at 285°, carbonises at about 300°; 8-*chloroanthracoumarin*, obtained in a similar way from *m*-chlorocinnamic acid, forms brown crystals, m. p. 241°; gives on sublimation golden-yellow needles, m. p. 329°; 9-*aminoanthracoumarin*, obtained by condensing *p*-aminocinnamic acid and *m*-hydroxybenzoic acid, and the corresponding *chloro*-compound, were also prepared, but their properties are not recorded. G. A. R. K.

A Synthesis of Pyrylium Salts of Anthocyanidin Type. III. A New Synthesis of Pelargonidin Chloride. D. D. PRATT and R. ROBINSON (*J. Chem. Soc.*, 1924, **125**, 188—199).—Phloroglucinol dimethyl ether on treatment with formanilide and phosphoryl chloride, followed by subsequent decomposition, yields 2-hydroxy-4 : 6-dimethoxybenzaldehyde and a smaller relative amount of 4-hydroxy-2 : 6-dimethoxybenzaldehyde. When hydrogen chloride is passed into a cold solution of the 2-hydroxy-compound in the presence of ω-4-dimethoxyacetophenone, a good yield of tetramethylpelargonidin chloride (annexed formula) is obtained. On demethylation, pelargonidin chloride is produced. 4-Hydroxy-2 : 6-dimethoxybenzaldehyde on similar treatment gives a trimethylpelargonidin chloride. It is suggested that the blue coloration characteristic of pelargonidin and other anthocyanidins is dependent on the presence of at least four hydroxyl groups, as well as on their positions. 3 : 7-*Dihydroxy-2-phenylbenzopyrylium chloride* crystallises in orange-brown prisms, decomposing at 184°. 3 : 7 : 4'-*Trihydroxy-2-phenylbenzopyrylium chloride*, $C_{15}H_{11}O_4Cl,H_2O$, crystallises



in needles, and decomposes at 262°. 4-*Hydroxy*-2 : 6-*dimethoxybenzaldehyde* crystallises in colourless prisms, m. p. 190°. *Trimethylgalangidin ferrichloride* (3 : 5 : 7-*trimethoxy*-2-*phenylbenzopyrylium ferrichloride*) forms yellowish-brown prisms, m. p. 174°. The *trimethylgalangidin chloride* crystallises in orange-red needles.

F. G. P.

A Synthesis of Pyrylium Salts of Anthocyanidin Type. IV. Flavylium Salts related to Chrysin, Apigenin, and Luteolin. D. D. Pratt, R. Robinson, and P. N. Williams (*J. Chem. Soc.*, 1924, **125**, 199—207; cf. previous abstract).—A series of compounds related to the flavones has been obtained and a system of nomenclature based on names suggesting their relationship to particular flavones and having the termination *-idin* suggested. Thus (I) is luteolidin chloride. The dimethyl ether of chrysinidin chloride is obtained by the action of hydrogen chloride on acetophenone in the presence of 2-hydroxy-4 : 6-dimethoxybenzaldehyde, and has been isolated as a ferrichloride. With phloroglucinol, *p*-anisyl β-hydroxyvinyl ketone reacts in the presence of hydrogen chloride to give acacetidin chloride (II). Trimethylapigenidin ferrichloride has been prepared from 2-hydroxy-4 : 6-dimethoxybenzaldehyde and acetylanisole. *Dimethylchrysinidin ferrichloride*, $C_{17}H_{15}O_3Cl_4Fe$, crystallises in reddish-brown prisms, m. p. 178°. p-*Anisyl β-hydroxyvinyl ketone*, $OMe\cdot C_6H_4\cdot CO\cdot CH{:}CH\cdot OH$, can be isolated as a *copper* salt, green prisms, m. p. 206—207°. 7-*Hydroxy*-4′-*methoxy*-2-*phenylbenzopyrylium chloride*, $C_{16}H_{13}O_3Cl,2H_2O$, brownish-orange needles, decomposes at 182—183°; its *picrate* melts at 219—221°. *Acacetidin chloride* forms brown prisms, m. p. >360°; *trimethylapigenidin ferrichloride*, orange needles; 2-*hydroxy*-4 : 6-*dimethoxystyryl* 3 : 4-*dimethoxyphenyl ketone*, yellow prisms, m. p. 178—179°; *tetramethyl-luteolidin ferrichloride*, salmon-red needles, m. p. 206—207°.

F. G. P.

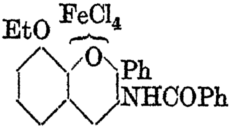
Some Derivatives of Benzopyrylium. R. Robinson and (in part) H. G. Crabtree, C. R. Das, W. Lawson, R. W. Lunt, B. H. Roberts, and P. N. Williams (*J. Chem. Soc.*, 1924, **125**, 207—214).—The oxonium salts described have been prepared by the method of synthesis, which depends on the condensation of a derivative of salicylaldehyde and a substance containing the group $-CO\cdot CH_2-$, under the influence of hydrogen chloride. 4-*Methoxyphenyl* 2-*hydroxy*-5-*methylstyryl ketone*,

$$OH\cdot C_6H_3Me\cdot CH{:}CH\cdot CO\cdot C_6H_4\cdot OMe,$$

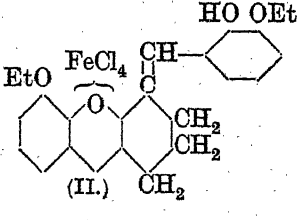
forms yellow plates, m. p. 151—152°; 4′-*methoxy*-2-*phenyl*-6-*methyl*-

benzopyrylium ferrichloride, $C_{17}H_{15}O_2Cl_4Fe$, obtained from the ketone, crystallises in crimson needles, m. p. 165—166°. *Phenyl 2-hydroxy-3-methoxystyryl ketone*, $MeO\cdot C_6H_3(OH)\cdot CH{:}CH\cdot COPh$, crystallises in yellow prisms, m. p. 112°. 8-*Methoxy-2-phenylbenzopyrylium ferrichloride*, from the ketone, crystallises in reddish-brown needles, m. .p. 157°. 8 : 4′-*Dimethoxy-2-phenylbenzopyrylium ferrichloride*, obtained from *o*-vanillin and *p*-methoxyacetophenone, crystallises in brown needles, m. p. 180°. 2 : 3 : 4-*Trimethoxyphenyl 2-hydroxy-3-methoxystyryl ketone*, obtained from *o*-vanillin and gallacetophenone trimethyl ether, forms bright yellow needles, m. p. 145°. 2′-*Hydroxy*-8 : 3′ : 4′-*trimethoxy-2-phenylbenzopyrylium ferrichloride* forms dark red needles, m. p. 194°; the *picrate*, red prisms, m. p. 164°; the *periodide*, purple needles, m. p. 133°; the *mercurichloride*, yellow needles, m. p. 143°. 2-*Phenyl*-3 : 4′-*dimethylbenzopyrylium ferrichloride*, from salicylaldehyde and *p*-tolyl ethyl ketone, forms yellow needles, m. p. 165—166°. 8-*Methoxy-2-phenyl*-3 : 4′-*dimethylbenzopyrylium ferrichloride* from *o*-vanillin and *p*-tolyl ethyl ketone, forms orange-brown needles, m. p. 172°; 8-*methoxy*-2-α-*naphthylbenzopyrylium ferrichloride*, from *o*-vanillin and α-naphthyl methyl ketone, brownish-red needles, m. p. 230°; 2′-*hydroxy*-3′-*methoxy-2-benzylidene*-1-*hydrindone*, from *o*-vanillin and α-hydrindone, yellow needles, m. p. 198°; 8-*methoxy*-2 : 3-*indeno*-(1 : 2)-*benzopyrylium ferrichloride*, red needles, m. p. 187—188°. F. G. P.

Some Benzopyrylium Salts. L. R. RIDGWAY and R. ROBINSON (*J. Chem. Soc.*, 1924, **125**, 214—222).—Attempts to prepare a benzopyrylium salt in which a halogen atom occurs in position 3 have not so far succeeded. The attachment of nitrogen to the pyrylium nucleus has been successful, and 3-benzoylamino-8-ethoxy-2-phenylbenzopyrylium ferrichloride (I) has been prepared from 2-hydroxy-3-ethoxybenzaldehyde and ω-benzoylaminoacetophenone. The removal of the benzoyl group from this salt was not possible. An account is included of some compounds which have been prepared in order to throw light on the property of fluorescence in relation to structure in this group. 8-*Ethoxy-2-phenylbenzopyrylium ferrichloride*, $C_{17}H_{15}O_2Cl_4Fe$, forms brown plates, m. p. 139—140°; 3-*benzoylamino*-8-*ethoxy*-2-*phenylbenzopyrylium ferrichloride* (I), orange-red needles, m. p. 198°; 3-*benzoylamino*-4′-*methoxy*-8-*ethoxy*-2-*phenylbenzopyrylium ferrichloride*, $C_{25}H_{22}O_4NCl_4Fe$, reddish-brown plates, m. p. 201°. 5-*Ethoxy*-4-(2-*hydroxy*-3-*ethoxybenzylidene*)-1 : 2 : 3 : 4-*tetrahydroxanthylium ferrichloride* (II) is obtained from cyclohexanone and 2-hydroxy-3-ethoxybenzaldehyde. It is a chocolate-coloured powder, m. p. 197°. The chloride obtained from this when boiled with water containing a



(I.)



(II.)

little hydrochloric acid is converted into *diethoxytrimethylenedibenzo-spiropyran* (III), colourless needles, m. p. 155°. *α-Naphthylmethoxymethyl ketone*, $C_{10}H_7\cdot CO\cdot CH_2\cdot OMe$, is obtained from methoxyacetonitrile and magnesium α-naphthyl bromide. It is a pale yellow, viscid oil, b. p. 184—186°/13 mm. It condenses with 2-hydroxy-5-methylbenzaldehyde to *3-methoxy-2-α-naphthyl-6-methylbenzopyrylium chloride*, $C_{21}H_{17}O_2Cl,3H_2O$, orange needles, m. p. 84°. The *ferrichloride* crystallises in plates, m. p. 184°. With 2-hydroxy-3-ethoxybenzaldehyde the above ketone yields *3-methoxy-8-ethoxy-2-α-naphthylbenzopyrylium chloride*, $C_{22}H_{18}O_3Cl,2H_2O$, orange-red plates, m. p. 115—116°, whilst with β-hydroxy-α-naphthaldehyde, *3-methoxy-2-α-naphthyl-naphtha-*(2 : 1)*-pyrylium chloride* (IV) is obtained in red, microscopic plates, m. p. 94°. The *ferrichloride* forms bright red plates, m. p. 183°. 6 : 4′*-Dimethoxy-2-phenylbenzopyrylium chloride* forms orange-red plates, m. p. 135°; the *ferrichloride* crystallises in brownish-red plates, m. p. 192—193°. 8-*Methoxy*-β-*naphthacoumarono*-(β : α-2 : 3)-*benzopyrylium chloride* (V) is prepared from *o*-vanillin and β-naphthacoumaranone. It crystallises in green prisms, m. p. 236—240°. When warmed with ethyl alcohol and a trace of sodium acetate, it is decolorised and the colourless *ethyl ether* of the pyranol is obtained in the form of needles, m. p. 165°.

F. G. P.

“ Tervalent ” Carbon. I. The Tetra-arylallyl Radicals and their Derivatives. K. Ziegler [with G. Bremer, F. Thiel, and F. Thielmann] (*Annalen*, 1923, **434**, 34—78; cf. A., 1922, i, 1047).—This investigation was undertaken to determine the factors responsible for the dissociation of poly-substituted ethane derivatives. For this purpose, compounds of the type of octaphenyldiallyl were studied. Assuming that the theoretical considerations developed by Thiele and Werner are correct, the unsaturated ββ-diphenylvinyl group would possess a markedly higher degree of “ valency requirement ” than the relatively saturated phenyl residue. Comparison of the dissociation capacity of the diallyl derivatives with that of the hexaphenylethanes provides a test for the accuracy of the theoretical considerations advanced by various authors. The first results of the work are given in an earlier paper (*loc. cit.*). 9-ββ-*Diphenylvinylxanthenol*,  $O<\genfrac{}{}{0pt}{}{C_6H_4}{C_6H_4}>C<\genfrac{}{}{0pt}{}{OH}{CH:CPh_2}$, has now been obtained in needles which on heating lose water and pass into the allene derivative. Characteristic salts are obtained, particularly the *perchlorate,* as well as acid halogenides such as the *chloride-hydrochloride,*  $O<\genfrac{}{}{0pt}{}{C_6H_4}{C_6H_4}>C(Cl,HCl)\cdot CH{:}CPh_2$, red needles, m. p. 156—157°, and the *bromide hydrobromide,* m. p. 130—131°; perhalogenides, namely, the *chloride tetrabromide* and *bromide tetrabromide,* reddish-brown powders, decomp. 123—124°, and 128—129°, respectively. Double salts of the xanthyl chloride are obtained by addition of heavy metal salts to solutions of the chloride hydrochloride in glacial acetic acid. The *zinc chloride* salt is a red, crystalline solid, decomposing at 165—166°. Hydrolysis of the salts regenerates the xanthenol, whilst tertiary amines such as pyridine and dimethylaniline convert them into the allene derivatives. Methyl and ethyl alcohols convert the hydrohalogenides into 9-*methoxy-* and 9-*ethoxy*-9-ββ-*diphenylvinylxanthen,* crystallising in needles, m. p. 133—134° and 136—137°, respectively. These ethers are readily decomposed by acids into alcohol and the coloured salts. The salts, particularly the chloride hydrochloride, dissolve in saturated alcoholic hydrogen chloride unaltered, and on reduction by zinc the parent substance, 9-ββ-*diphenylvinylxanthen,* has been obtained in large, colourless crystals, m. p. 164—165°. This has also been obtained from 9-xanthylacetic acid by the Grignard reaction. Aryl and alkyl derivatives of 9-ββ-diphenylvinylxanthen are obtained by the action of the Grignard reagent on the xanthyl salts, particularly on the perchlorate. The xanthen and its alkyl and aryl derivatives are easily reduced by hydriodic acid, the ββ-diphenylvinyl group probably being eliminated as αα-diphenylethane. 9-*Ethyl*-9-ββ-*diphenylvinylxanthen* crystallises in colourless crusts, m. p. 129—130°. These xanthens, when acted on by bromine, yield perbromides such as  $O<\genfrac{}{}{0pt}{}{C_6H_4}{C_6H_4}>C(Br\cdot Br_x)H$, and brominated compounds of the type of αββ-*tribromo-αα-diphenylethane,* $Ph_2CBr\cdot CHBr_2$, m. p. 88—89°. Di-*p*-anisyl ketone and 2 : 4 : 4′-trimethoxybenzophenone, on treatment with the magnesium compound of ββ-diphenylvinyl bromide, yield alcohols, $(MeO\cdot C_6H_4)_2CR\cdot CH{:}CPh_2$ and $(MeO)_2C_6H_3(MeO\cdot C_6H_4)\cdot CR\cdot CH{:}CPh_2$, from which crystalline perchlorates may be prepared. The *trimethoxy*-compound forms fine red crystals yielding violet-red solutions. Pyridine converts it into 2 : 4 : 4′-trimethoxydiphenyl-γγ-diphenylallene, $(MeO)_2C_6H_3\cdot C(C_6H_4OMe){:}C{:}CPh_2$, colourless crystals, m. p. 134—135°. Tetraphenylpropene derivatives have been prepared, *ααγγ-tetraphenylallyl ethyl ether,* $Ph_2C(OEt)\cdot CH{:}CPh_2$, resulting from the action of alcoholic sulphuric acid on the corresponding alcohol. It forms colourless crystals, m. p. 106—107°. *Tetraphenylallyl perchlorate,* obtained from tetraphenylallyl alcohol, is an unstable, chocolate-brown powder, decomposing at 63—64°. On keeping, it is converted into the colourless 1 : 1 : 3-triphenylindene. Results show that the coloured compounds of the substituted tetra-allylallenes are true tetra-arylallyl salts, that tetra-arylallyl alcohols are pseudo-bases; the chlorides were not isolated, losing hydrogen chloride and giving tetra-allylallenes; these allenes readily add acid so as to form salts. Magnesium aryl haloids convert the xanthen perchlorate into the free *di*-9-ββ-*diphenylvinylxanthyl*,  $O{<}\begin{matrix}C_6H_4\\C_6H_4\end{matrix}{>}C\cdot CH{:}CPh_2$, a colourless, crystalline powder, m. p. 144—145°, sparingly soluble in most reagents. This dissolves in benzene with a yellow colour, the solution becoming brown on warming, turning yellow again on cooling. Air completely decolorises the solution, a peroxide,

$$\left[O{<}\begin{matrix}C_6H_4\\C_6H_4\end{matrix}{>}C(O-)\cdot CH{:}CPh_2\right]_2,$$

being obtained. Bromine converts the coloured solution into 9-ββ-diphenylvinylxanthyl bromide tetrabromide. Hydrazobenzene reduces it to 9-ββ-diphenylvinylxanthen (cf. triphenylmethyl). Sodium and potassium give coloured metal derivatives, the potassium derivative crystallising in the form of a copper-red sludge. Dry air decolorises the solutions of the alkali metal derivatives, water also decomposes them with production of the xanthen, whilst ethyl bromide converts them into the ethylxanthene. Tetraphenylhydrazine converts the free radical into 9-ββ-*diphenylvinylxanthyldiphenylamine*,  $O{<}\begin{matrix}C_6H_4\\C_6H_4\end{matrix}{>}C(NPh_2)\cdot CH{:}CPh_2$, crystallising in colourless plates, m. p. 194—196° (cf. triphenylmethyl). These analogies with hexaphenylethane show that the xanthyl compound in solution exhibits radical dissociation. Molecular-weight determinations in naphthalene show that the xanthyl is decomposed to the extent of about 60% into 2 mols. of radical-like form. The free tetra-arylallyl radicals are also obtained by the decomposition of the corresponding perchlorates with the Grignard reagent. *Dianisyldiphenylallyl*, $(MeO\cdot C_6H_4)_2\cdot C\cdot CH{:}CPh_2$, crystallises in dark green plates, 2 : 4 : 4′-*trimethoxydiphenyl-γγ-diphenylallyl*,

$$(MeO)_2\cdot C_6H_3\cdot C(C_6H_4OMe)\cdot C\cdot CH{:}CPh_2,$$

is similar, but the colour is deeper. *ααγγ-Tetraphenylallyl*, the parent substance, is a green, crystalline powder, molecular-weight determinations in benzene showing a degree of dissociation of 80%. These three compounds are exceedingly stable. The corresponding peroxides are very unstable. The sodium compounds of the allyl radicals are readily converted into the corresponding propenes. In the triarylmethyl series, the union of the two benzene nuclei through oxygen opposes the association of the radicals, for 9-phenylxanthyl in naphthalene is present to the extent of about 50—70% in the unimolecular form and about 30—50% in the bimolecular form, whilst hexaphenylethane under like conditions is only dissociated to the extent of 15—25%. Tetraphenylallyl, on the other hand, in benzene solution at 4°, is present in the bimolecular form to the extent of at most 20%, whilst 9-ββ-diphenylvinylxanthyl in naphthalene at 80° is present perhaps to the extent of 40%; at 4°, therefore, it is still more strongly associated. If, according to Thiele and Werner, the high valency requirement of a residue is explained by its unsaturated character, based on the principle of a distribution of affinity, the existence of tetra-arylallyl radicals is a weighty argument in favour of this principle. αα-Diphenylethylene is essentially more unsaturated than benzene, so that it must be assumed that the ββ-diphenylvinyl residue requires more valency than the phenyl residue, and in agreement with this it is found that on replacing two phenyl residues in hexaphenylethane by two such residues the tendency to dissociate is very much increased.

F. G. P.

Atropine Phosphates. L. Debucquet (*J. Pharm. Chim.*, 1924, **29**, 15—22).—The salt $C_{17}H_{23}O_3N,H_3PO_4$ is obtained in 92% yield when an alcoholic solution containing equimolecular quantities of atropine and phosphoric acid is heated for half an hour in a water-bath at 90—95°, and then left to crystallise. Small, lustrous crystals (m. p. 196°) are obtained which are soluble in rather less than five times their weight of water (giving a solution acid to litmus), sparingly soluble in cold alcohol and almost insoluble in ether and chloroform. Attempts to prepare the salt, $(C_{17}H_{23}O_3N)_2,H_3PO_4$, gave only the monobasic phosphate (in diminished yield) and unchanged atropine. W. T. K. B.

Stereoisomerism and Local Anæsthetic Action in the β-Eucaine Group. Resolution of β- and *iso*-β-Eucaine. H. King (*J. Chem. Soc.*, 1924, **125**, 41—57).—On benzoylation, α- and β-vinyldiacetonalkamines yield *O*-benzoyl derivatives and for convenience the name of *iso*-β-eucaine is proposed for the derivative of the β-compound. β-Eucaine has been resolved by means of camphorsulphonic acid. With *d*-camphor-10-sulphonic acid, the partial racemate, dl-β-*eucaine* d-*camphor*-10-*sulphonate*, was obtained, working between the ordinary temperature and zero, and it has been found possible to resolve this salt by means of the more soluble active forms which are unstable in respect of the partial racemate, a total yield of 54% of l-β-*eucaine* d-*camphorsulphonate* being obtained. Owing to the formation of a continuous series of mixed crystals between the two active salts, the more soluble *d*-β-eucaine *d*-camphorsulphonate could not be isolated, but the isolation of d-β-*eucaine* l-*camphorsulphonate* was finally accomplished by the use of *l*-camphor-10-sulphonic acid. *iso*-β-Eucaine was resolved by the use of *d*-α-bromocamphor-π-sulphonic acid. In this case the salts, being of approximately equal solubility, separate alternately from the solution on fractional crystallisation. On the rabbit's cornea *r*-β-eucaine, *r*-*iso*-β-eucaine and their optically active components have approximately equal local anæsthetic action; on the sciatic nerve of the frog, however, β-eucaine is a more powerful anæsthetic than *iso*-β-eucaine. dl-β-*Eucaine* d-*camphorate* forms plates, m. p. 211—212°; the l-*malate* has m. p. 212—213° and $[\alpha]_D$ $-2{\cdot}6°$; the d-*tartrate* crystallises in tablets which have m. p. 257° and $[\alpha]_D$ $+10{\cdot}1°$. The *d*-camphor-10-sulphonate (mono-alcoholate) forms tablets, m. p. 228—229°, $[\alpha]_D$ $+10{\cdot}3°$ (anhydrous salt). *l*-β-Eucaine *d*-camphorsulphonate forms leaflets, m. p. 248—249°, $[\alpha]_D$ 4·78° and 4·83°, whence the *l*-β-eucainium-ion has $[\alpha]_D$ $-11°$. *d*-β-Eucaine *l*-camphorsulphonate has $[\alpha]_D$ $-5{\cdot}09°$, whence the *d*-β-eucainium-ion has $[\alpha]_D$ $+10{\cdot}6°$. l-β-*Eucaine* forms prisms, m. p. 57—58°. The *hydrochloride* forms plates (m. p. 244—245°, $[\alpha]_D$ −11·3°), the *picrate* (small prisms) having m. p. 198—199°. d-β-*Eucaine* has m. p. 57—58°, the *hydrochloride* having $[\alpha]_D$ +11·5°. r-β-*Eucaine hydrochloride* forms tablets, m. p. 277—279°; the free *base* has m. p. 70—71°; the *picrate* (plates), has m. p. 230·5—231·5°. d-α-*Vinyldiacetonalkamine hydrochloride* (tablets, m. p. above 300°), has $[\alpha]_D$ +13·3°; the l-*hydrochloride* has m. p. above 300° and $[\alpha]_{5461}$ −18·5°. The l-*base* forms prisms, m. p. 79—81° (*picrate*, needles, m. p. 242—244°). N-*Benzoyl*-β-*vinyldiacetonalkamine*, obtained by benzoylation of the β-alkamine base, forms leaflets, m. p. 121—122°; the O-*benzoyl* derivative, obtained by benzoylating the hydrochloride, forms needles or plates, m. p. 269—271°. Its *picrate* has m. p. 256—258°. l-iso-β-*Eucaine* d-α-*bromocamphor*-π-*sulphonate* forms needles, m. p. 236—238°, and has $[\alpha]_{5461}$ +52·1°, and $[M]_{5461}$ +290·9°, whence $[M]_{5461}$ for the *l-iso*-β-eucainium-ion is −55·6°. d-iso-β-*Eucaine* d-α-*bromocamphor*-π-*sulphonate* forms needles containing 0·5—1 mol. H_2O, the anhydrous salt having $[\alpha]_{5461}$ +70°, $[M]_{5461}$ +390°, whence the *d-iso*-β-eucainium-ion has $[\alpha]_{5461}$ +17·8°. d-iso-β-*Eucaine hydrochloride* forms needles, m. p. 271—273°, $[\alpha]_{5461}$ +14·9°. The l-*hydrochloride* has m. p. 271—273°, and $[\alpha]_{5461}$ −14·25°. The l-*picrate* forms needles, m. p. 280°. d-β-*Vinyldiacetonalkamine hydrochloride*, tablets, has m. p. 217—219°, $[\alpha]_{5461}$ +22·85°. The *base* has m. p. 121—123°; the *picrate* (needles) has m. p. 181—182°. ON-*Dibenzoyl*-α-*vinyldiacetonalkamine*, obtained by benzoylation of β-eucaine base, crystallises in plates, m. p. 142—143°. The similar *dibenzoyl* derivative from the *iso*-β-eucaine base forms prisms, m. p. 114—115°. F. G. P.

Complex Thiocyanates of Tervalent Metals. III. G. Scagliarini and G. Tartarini (*Gazzetta*, 1923, **53**, 876—878).—Unlike vanadium (A., 1923, i, 547, 1225), molybdenum forms complex thiocyanates which are highly stable and resemble, indeed, those of chromium.

Piperidine vanadihexathiocyanate, $(C_5H_{11}N{\cdot}H)_3[V(SCN)_6]$, forms deep red acicular crystals; *basic pyridine vanaditetrathiocyanate*, $(C_5H_5N{\cdot}H)_3\left[V\begin{matrix}(SCN)_4\\(OH)_2\end{matrix}\right]$, small, brick-red crystals; *hexamethylenetetramine molybdihexathiocyanate*, $(C_6H_{12}N_4{\cdot}H)_3[Mo(SCN)]_6$, straw-yellow crystals; *basic pyridine molybdipentathiocyanate*,

$$(C_5H_5N{\cdot}H)_3[Mo(SCN)_5OH],$$

orange-yellow crystals; and *basic piperidine molybdipentathiocyanate*, $(C_5H_{11}N{\cdot}H)_3[Mo(SCN)_5OH]$, brick-red crystals.

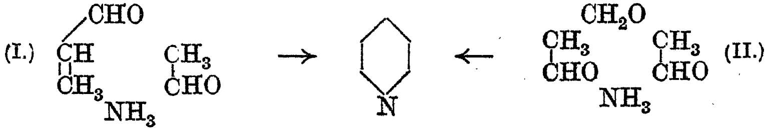
Galegine. Barger and White.—(See i, 272.)

The Synthesis of Pyridine from Aldehydes and Ammonia. A. E. Tschitschibabin and (Mlle.) M. P. Oparina (*J. Russ. Phys. Chem. Soc.*, 1924, **54**, 601—606; cf. A., 1923, i, 1121 *et seq.*).—Pyridine can theoretically be formed by the interaction of ammonia either with one molecule of acraldehyde and one of acetaldehyde (scheme I) or with two molecules of acetaldehyde and one of formaldehyde (scheme II), thus:



Either scheme would account for the formation of small quantities of pyridine in the experiments of Stöhr (A., 1891, 579; 1892, 628), because it is well known that acraldehyde is formed from formaldehyde and acetaldehyde and that the process is reversible.

It is now shown that mixtures of acraldehyde and acetaldehyde or of acetaldehyde and ethylal can be made to react with ammonia under the influence of alumina (*loc. cit.*), yielding pyridine as the main product. In the former case, some β-picoline and a small quantity of α-picoline were also obtained, whilst in the second case α-, β-, and γ-picoline and 3 : 5-dimethylpyridine were isolated in small quantities. The formation of β-picoline from ethylal, acetaldehyde, and ammonia is doubtless due to the intermediate formation of acraldehyde, which then reacts with ammonia, whilst pyridine can be produced according to either scheme (I) or (II).

G. A. R. K.

4-Methyl-2-ethylpyridine. A. E. Tschitschibabin (*J. Russ. Phys. Chem. Soc.*, 1924, **54**, 607—610).—Pure γ-picoline, regenerated from its picrate, was heated with ethyl iodide in sealed tubes at 310—325° and the new base isolated in the form of its *picrate*, short yellow prisms, m. p. 120—121°; the *base*, regenerated from this picrate, boiled at 172° and was characterised by the formation of the *chloroplatinate*, short, sparkling, orange prisms, m. p. 176° (decomp.), and the *chloroaurate*, yellow prisms, m. p. 80°. The synthesis of 4-methyl-2-ethylpyridine has since been described by Eckert and Loria (A., 1918, i, 79), but the properties of the derivatives prepared by them differ somewhat from those given above.

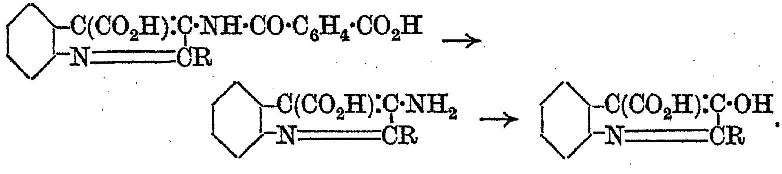
G. A. R. K.

The Condensation of Acetylene with Ammonia in the Presence of Alumina. A. E. Tschitschibabin and P. A. Moschkin (*J. Russ. Phys. Chem. Soc.*, 1924, **54**, 611—624).—A preliminary account of this work has already been published (A., 1915, i, 638); a detailed description is now given of the method of synthesis and of the separation of the pyridine bases formed by the fractional precipitation of their picrates. Pyrrole bases were found to be present; of the crude condensation product, some 30% consisted of picolines, which were isolated in the form of their picrates and, by crystallising the latter from acetone, were shown to consist of the α-compound with small quantities of the γ-isomeride. The collidine fraction constituted about 10% of the original mixture. The separation was again effected through the picrates, which were crystallised from ethyl acetate. The presence of β-collidine (4-methyl-3-ethylpyridine, chloroaurate, m. p. 140—141°, chloroplatinate, m. p. 215° [decomp.], picrate, m. p. 149°), identical with that obtained from cinchonine, and 2-methyl-5-ethylpyridine (picrate, m. p. 164°, chloroaurate, m. p. 88°) was confirmed. In addition, two other *collidines* were isolated, one of b. p. 178—182°/756·7 mm. (*picrate*, orange rods, m. p. 143°; *chloroaurate*, m. p. 119—121°; *chloroplatinate*, m. p. 207° [decomp.]), and another of b. p. 185·5—186·5°/756·7 mm. (*picrate*, short, flattened, orange needles, m. p. 134°; *chloroaurate*, plates, m. p. 116—118°; *chloroplatinate*, orange crystals, m. p. 210° [decomp.]). These collidines do not appear to be identical with 4-methyl-2-ethylpyridine (preceding abstract) or with either 2 : 3 : 4- or 2 : 3 : 6-trimethylpyridine which might possibly have been produced; but it is thought that the compounds may not be pure.

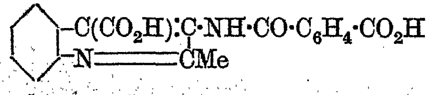
G. A. R. K.

The Absorption Spectra of some Indole Derivatives. F. W. Ward (*Biochem. J.*, 1923, **17**, 891—897).—Using the Hilger ultra-violet spectrum photometer, the absorption spectra of the following compounds have been charted : indole, indole-3-carboxylic acid, indole-3-aldehyde, indole-3-ethyl alcohol, indole-3-propionic acid, indole-3-alanine (tryptophane), 2 : 3-dihydroxyindole, 2-hydroxy-3-indole-aldehyde, isatin, and sodium indigotinsulphonate. The effect of substitution in the indole nucleus is discussed. J. P.

Certain Quinoline-4-carboxylic Acids. S. Berlingozzi and C. Marzella (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 403—406; cf. A., 1923, i, 482, 847).—The action of acetonyl- or phenacyl-phthalimide on isatoic acid gives rise, in the usual way, to compounds of the type :



When heated beyond their melting points, all these quinoline-4-carboxylic acids lose carbon dioxide, yielding the corresponding 3-amino- and 3-hydroxy-quinolines (*loc. cit.*). Those of the above acids which have a phenyl group in the 2-position may be regarded as derivatives of 2-phenylquinoline-4-carboxylic acid so largely used in therapeutics.



The *compound* (annexed formula) obtained from isatoic acid and acetonylphthalimide, crystallises in minute, white needles, m. p. 267—268° (decomp.).

3-*Amino-2-methylquinoline-4-carboxylic acid*, $C_{11}H_{10}O_2N_2$, obtained, together with phthalic acid, when the preceding compound is boiled with concentrated hydrochloric acid, forms lemon-yellow prisms, m. p. 232—233° (decomp.), yields solutions which develop fluorescence on addition of a mineral acid, and gives 3-amino-2-methylquinoline when heated at 233—235°. Its *acetyl* derivative forms a white, microcrystalline powder, m. p. 272—273°.

3-*Hydroxy*-2-*methylquinoline*-4-*carboxylic acid*, prepared by the action of nitrous acid on the preceding amino-compound, forms minute, pale yellow crystals, m. p. 229—230° (decomp.), and is converted into 3-hydroxy-2-methylquinoline when fused; its alcoholic solutions are fluorescent and are coloured red by ferric chloride.

The *compound* formed by condensation of isatoic acid with phenacylphthalimide crystallises in lustrous, straw-yellow scales, m. p. 260° (decomp.).

3-*Amino*-2-*phenylquinoline*-4-*carboxylic acid* forms pale yellow needles and prismatic plates, m. p. 226° (decomp.), exhibits fluorescence in acid solution, and gives 3-amino-2-phenylquinoline when heated. Its *acetyl* derivative crystallises in lustrous, white scales, m. p. 257—258°.

3-*Hydroxy*-2-*phenylquinoline*-4-*carboxylic acid* is obtained as a lemon-yellow, microcrystalline powder, m. p. 206—207°, forms fluorescent alcoholic solutions which are reddened by ferric chloride, and gives 3-hydroxy-2-phenylquinoline when heated. T. H. P.

The Absorption Spectra of Kynurenic Acid and some Related Quinoline Compounds. F. W. WARD (*Biochem. J.*, 1923, **17**, 903—906).—The absorption spectra of quinoline, quinaldine, lepidine, quinaldinic acid, 2 : 6-dimethylquinoline, kynurenic acid, and of quinolylacetaldehyde have been mapped. The last-mentioned compound gives an abnormal spectrum and doubts are expressed as to its constitution. The effects of substituents in the quinoline nucleus are discussed. J. P.

Some Heterocyclic Derivatives of Substituted *o*-Aminophenols. A. KORCZYNSKI and ST. OBARSKI (*Bull. Soc. chim.*, 1923, **33**, [iv], 1823—1832).—4-Chloro-2-nitrophenol, on electrolytic reduction, gave 4-*chloro*-2-*aminophenol* (m. p. 185°; *diacetyl* derivative, m. p. 201°). The following were prepared in a similar manner: 4-*chloro*-6-*bromo*-2-*aminophenol* (*acetyl* derivative, m. p. 150°), 4-bromo-2-aminophenol, 4 : 6-dibromo-2-aminophenol, and 4 : 6-di-iodo-2-aminophenol.

4-Chloro-2-aminophenol, on heating with acetamide (cf. Niementowski, A., 1898, i, 210) gave 4-*chloro*-1-*methylbenzoxazole* (m. p. 63°). The following compounds were obtained in a similar manner: 4-*bromo*-1-*methylbenzoxazole* (m. p. 70°), 4-*chloro*-6-*bromo*-1-*methylbenzoxazole* (m. p. 117°), and 5 : 6-*dibromo*-1-*methylbenzoxazole* (m. p. 127°). All the above oxazoles form yellow needles.

4-Chloro-2-aminophenol was converted (cf. Chetmicki, A., 1887, 477) by thiocarbonyl chloride, in presence of pyridine, into 4-*chloro*-1-*thiolbenzoxazole* (m. p. 283°), and the following compounds were prepared in a similar manner: 4-*chloro*-6-*bromo*-1-*thiolbenzoxazole* (m. p. 228°) and 4 : 6-*dibromo*-1-*thiolbenzoxazole* (m. p. 235°). All the above thiol derivatives form yellow needles, soluble in alkali.

4-Bromo-2-aminophenol (2 mols.) on boiling in alcoholic solution with chloroanil (1 mol.) affords 8-*bromo*-4-*aminophenoxazone* (giving a blue solution in concentrated sulphuric acid), the following compounds being similarly prepared: 8-*chloro*-2 : 10-*dibromo*-4-*aminophenoxazone* (reddish-violet solution in concentrated sulphuric acid), 2 : 8 : 10-*tribromo*-4-*aminophenoxazone*, and 2 : 8 : 10-*tri-iodo*-4-*aminophenoxazone* (blue solution in concentrated sulphuric acid). The above phenoxazones form red needles, not melting at 300°.

Chloroanil converts 4-nitro-2-aminophenol into a *substance* which forms orange-red needles. E. E. T.

Diphenylyl Phenylenediamines and the Colour of their Oxidation Products. J. Piccard and F. Abouchy (*Helv. Chim. Acta*, 1924, **7**, 75—83).—To compare the auxochromic effect of the diphenylyl group, $Ph\cdot C_6H_4-$, with those of phenyl and alkyl groups, the following derivatives of *p*-phenylenediamine were prepared, for oxidation into *meri*-quinonoid salts: *s*-di-*p*-diphenylyl-*p*-phenylenediamine (I); *s*-diphenyldi-*p*-diphenylyl-*p*-phenylenediamine (II), and tetra-*p*-diphenylyl-*p*-phenylenediamine (III). To prepare the first compound, (I), *p*-dibromobenzene was condensed with *p*-acetamidodiphenyl, giving s-*diacetyldi*-p-*diphenylyl*-p-*phenylenediamine*, colourless crystals, m. p. 245°. By alkaline hydrolysis this gave s-*di*-p-*diphenylyl*-p-*phenylenediamine*, long, colourless spangles, m. p. 256°. The second base, (II), was prepared in two ways, (*a*) by condensing (I) with iodobenzene, and (*b*) by condensing *p*-iododiphenyl with *s*-diphenyl-*p*-phenylenediamine. s-*Diphenyldi*-p-*diphenylyl*-p-*phenylenediamine* forms small crystals, m. p. 211°. The third base, (III), was also obtained in two ways, (*a*) by condensing (I) with *p*-iododiphenyl, and (*b*) by condensing *p*-di-iodobenzene with di-*p*-diphenylylamine. The product, *tetra*-p-*diphenylyl*-p-*phenylenediamine*, forms small, colourless crystals, m. p. 280°. Of these three bases, only the first can be oxidised to a quinonedi-imine. By oxidation with chromic acid, it gives *di*-p-*diphenylylbenzoquinonedi-imine*,

$$Ph\cdot C_6H_4N{:}C_6H_4{:}N\cdot C_6H_4\cdot Ph,$$

a red, amorphous powder, m. p. 266°. It is less basic than diphenylbenzoquinonedi-imine, and the colours of its salts are deeper; its mono-acid salts are blue, di-acid salts violet, and *meri*-quinonoid salts green. meri*Di*-p-*diphenylylbenzoquinonedi-imonium picrate*,

$$[Ph\cdot C_6H_4NH{:}C_6H_4{:}NH\cdot C_6H_4\cdot Ph{::::}Ph\cdot C_6H_4NH\cdot C_6H_4\cdot NH\cdot C_6H_4Ph][C_6H_2(NO_2)_3O]_2,$$

forms a bluish-green powder, m. p. 208°. A picrate of the *meri*-quinonoid salt of the second base was also isolated; it forms a yellowish-green powder, m. p. 169°. The colours of the *meri*-quinonoid salts of the three bases in solution are respectively bluish-green, green, and yellowish-green. The colours of the *holo*-quinonoid salts are only developed in concentrated sulphuric acid solution, and are respectively violet, bluish-violet, and blue. It is noted that glacial acetic acid dissolves the quinonedi-imine compounds as bases, the colour of the salts being developed only on addition of water. The leuco-compounds are weaker bases than the *holo*-quinonoid compounds, but the *meri*-quinonoid compounds are stronger bases than either of these. The auxochromic effect of the diphenylyl group in *meri*-quinonoid salts in the phenylenediamine, benzidine, or fuchsine series is less than that of two phenyl groups, but considerably greater than that of one group. The phenylated salts in the benzidine series are deeper in colour than the diphenylylated salts in the phenylenediamine series. The difference between the effect of the phenyl and diphenylyl groups is more marked in the *holo*-quinonoid than in the *meri*-quinonoid salts. It may be stated as a general rule that the weight of a group has more effect in the active chromophore than in an auxochromic group. E. H. R.

The Reaction of Carbon Disulphide on *p*-Phenylenediamine.

C. E. Bolser and E. B. Hartshorn (*J. Amer. Chem. Soc.*, 1923, **45**, 2349—2355).—When *p*-phenylenediamine and carbon disulphide are boiled in alcoholic solution (Pawlewski, A., 1899, ii, 405), a small quantity of *pp'*-diaminodiphenylthiocarbamide is produced, together with an insoluble compound, which has been described as *p*-phenylenethiocarbamide, $C_6H_4{<}^{NH}_{NH}{>}C{:}S$ (Lellmann, A., 1883, 185). This compound is now shown to be *di*-p-*phenylenedithiocarbamide*,  $C_6H_4{<}^{NH\cdot CS\cdot NH}_{NH\cdot CS\cdot NH}{>}C_6H_4$. In the first place, its formation may be almost entirely suppressed, the yield of diaminodiphenylthiocarbamide being correspondingly increased, by conducting the process in aqueous solution, by keeping the temperature of reaction low, and by decreasing the concentration of carbon disulphide. It is advisable frequently to remove, by filtration, the diaminodiphenylthiocarbamide, which is less soluble in warm alcohol than in hot, and still less soluble in water. This suggests that the simple thiocarbamide is an intermediate stage in the formation of the insoluble compound; that this is actually so is shown by the formation of the latter when carbon disulphide and *pp'*-diaminodiphenylthiocarbamide react in boiling alcoholic solution. The identity of the product with that formed directly from carbon disulphide and *p*-phenylenediamine is shown (although in neither reaction is an absolutely pure substance obtained) by the temperature of decomposition (285°), by the formation of *p*-phenylenediamine by the action of hot, concentrated acids, and by the formation of *p*-phenylenedithiocarbimide by the prolonged action of boiling acetic anhydride. The latter reaction proves that the compound has the above structure, since *p*-phenylenethiocarbamide could not give the dithiocarbimide, but should be converted into p-*acetamidophenylthiocarbimide*, white needles, m. p. 195—196°. The latter is produced by the action of boiling acetic anhydride on *di*-p-*acetamidophenylthiocarbamide*, a white solid, m. p. 235—237°, which is formed by the action of an excess of carbon disulphide on *p*-aminoacetanilide in boiling alcoholic solution. It was hoped that the hydrolysis of this derivative, which requires the use of hot, concentrated hydrochloric acid, might give di-*p*-aminophenylthiocarbamide (thus avoiding the concurrent formation of the insoluble compound), but actually phenylenediamine hydrochloride is the sole product.

The reduction, by means of stannous chloride and a mixture of glacial acetic acid and concentrated hydrochloric acid, of *azobenzene*-p-*thiocarbimide*, $Ph\cdot N{:}N\cdot C_6H_4\cdot NCS$, salmon-coloured needles, m. p. 94—95°, which is obtained by heating thiocarbonyl chloride and *p*-aminoazobenzene in carbon tetrachloride solution at 100°, gives diphenylenedithiocarbamide, but the latter does not appear until the solution is made alkaline. It is probable that the acid solution contains, in equilibrium with the dimeric compound, *p*-aminophenylthiocarbimide (hydrochloride). In fact, when the acetyl derivative (above) of the latter compound is boiled with glacial acetic acid, in the presence of this weaker acid diphenylenedithiocarbamide is precipitated, more of the same material being thrown down on dilution. It is evident that the tendency to the formation, by what is practically a tautomeric change, of this substance is so great, that free *p*-aminophenylthiocarbimide cannot exist, but, on liberation from its salts, immediately undergoes polymerisation. W. S. N.

New Methods of Splitting Pyrimidines. III. The Action of Iodine Solution on Pyrimidines. L. W. BASS and O. BAUDISCH (*J. Amer. Chem. Soc.*, 1924, **46**, 181—183; cf. A., 1922, ii, 328).—Pyrimidines with unsubstituted nitrogen atoms and with a double bond between carbon atoms 4 and 5 absorb iodine from solution in the presence of sodium bicarbonate. On distillation of the reaction mixtures, after removal of excess iodine, carbamide is found in the residues as a scission product. No carbamide can be detected before the distillation. Substitution by an alkyl group in position 5 retards the rapidity of decolorisation of iodine solution. Hydrouracil decolorises iodine solution, but no carbamide is formed when the reaction mixture is distilled. 1 : 3-Dimethylthymine does not decolorise iodine solution. Thymine itself yields carbamide and acetol; no pyruvic acid is formed. When bromine is substituted for iodine, the pyrimidine ring is not split under the conditions of the experiments. F. A. M.

New Methods of Splitting Pyrimidines. IV. A Study of the Mechanism of the Decomposition of Thymine. O. BAUDISCH and L. W. BASS (*J. Amer. Chem. Soc.*, 1924, **46**, 184—189; cf. preceding abstract).—The action of various oxidising agents on thymine has been studied; the primary products of the reactions still contain the carbamide residue. The final products, carbamide, acetol, and pyruvic acid, are formed only when the primary products are heated in aqueous solution with sodium hydrogen carbonate. Acetol is formed as a direct hydrolytic product of thymine, whilst pyruvic acid is formed by the complete hydrolysis of an intermediate oxidation product. A mechanism is suggested to explain the decomposition of thymine under the conditions used. F. A. M.

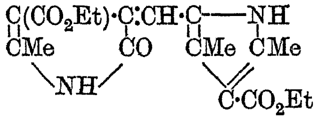
New Methods of Splitting Pyrimidines. V. The Action of Oxygen plus Ferrous Salts on Thymine under the Influence of Light. L. W. Bass (*J. Amer. Chem. Soc.*, 1924, **46**, 190—192; cf. preceding abstracts).—When in an atmosphere of oxygen aqueous solutions of thymine are illuminated using a quartz mercury arc, the pyrimidine is split to some extent into carbamide and pyruvic acid; no acetol is formed. The reaction is accelerated, but otherwise not affected, by ferrous sulphate or, to a smaller extent, by potassium ferrocyanide. No scission occurs in an atmosphere of nitrogen even in the presence of the above salts. F. A. M.

Catalysis. III. Reduction of Uracil to Hydrouracil. E. B. Brown and T. B. Johnson (*J. Amer. Chem. Soc.*, 1923, **45**, 2702—2708; cf. A., 1921, i, 806; 1922, i, 709).—Further experimental details are given, relating to the reduction of uracil to hydrouracil by means of hydrogen, in the presence of colloidal platinum. Colloidal palladium may also be used. Sulphur compounds, even when present only as traces, completely inhibit the reaction, but the chlorides of sodium, potassium, calcium, and magnesium are quite without effect. W. S. N.

Synthetic Researches on the Constitution of Bile-pigments. II. H. Fischer and J. Müller (*Z. physiol. Chem.*, 1924, **132**, 73—103).—If dry ammonia is passed through a cold alcoholic solution of ethyl α-acetyl-β-methylsuccinate, crystals are obtained, m. p. 77° (decomp.), apparently of ethyl β-amino-Δ^{β}-pentene-γδ-dicarboxylate, which on keeping or on warming in a vacuum at 40—50° completely change into ethyl 2-hydroxy-3 : 5-dimethylpyrrole-4-carboxylate, m. p. 127°, a compound which is also found in the mother-liquors from the crystals. This pyrrole derivative, when warmed in 50% sulphuric acid, yields α-methyl-lævulic acid, and when treated with hydrazine hydrate, is converted into the *hydrazide* of 2-hydroxy-3 : 5-dimethylpyrrole-4-carboxylic acid, sharp-angled leaflets, decomposing at 212°. This compound may be converted by nitrous acid into the *azide* of 3 : 5-dimethyl-2-hydroxypyrrole-4-carboxylic acid, flat prisms, which decompose explosively at 114°, and this compound, in solution in boiling absolute ethyl alcohol, yields *ethyl* 2-*hydroxy*-3 : 5-*dimethylpyrryl*-4-*carbamate*, white needles, decomposing at 148°, whilst if methyl alcohol is used, the corresponding *methyl carbamate* is obtained as white, glistening needles, decomposing at 164°. From ethyl acetylsuccinate, the following corresponding series of compounds is obtained: *ethyl* β-*amino*-Δ^{β}-*butene*-γδ-*dicarboxylate*, m. p. 122—124° (decomp.); ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate, m. p. 134°; (*hydrazide*, leaflets, decomposing at 232°; *azide*, needles, which decompose explosively at 135°; *methyl carbamate*, needles, m. p. 175°).

Ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate condenses with aldehydes in alcoholic solution in presence of hydrochloric acid, and the following compounds are described: *ethyl* 2-*keto*-3-*benzylidene*-5-*methyl*-2 : 3-*dihydropyrrole*-4-*carboxylate*, yellow leaflets,

m. p. 184°; *ethyl* 2-*keto*-3-p-*dimethylaminobenzylidene*-5-*methyl*-2 : 3-*dihydropyrrole*-4-*carboxylate*, red needles from alcohol, m. p. 231° (*hydrochloride*, yellow needles, unstable in air, decomposing at 210°, *perchlorate*, yellow needles, stable in air, m. p. 150° [decomp.]); *ethyl* 2-*keto*-3-o-*nitrobenzylidene*-5-*methyl*-2 : 3-*dihydropyrrole*-4-*carboxylate*, felted yellow needles, m. p. 201°; 4-*carbethoxy*-2-*hydroxy*-5-*methylpyrrolidyl*-3′-*carbethoxy*-2′ : 4′-*dimethylpyrrylmethene* (annexed formula), orange-yellow prisms, m. p. 210°, with which is also formed a *compound* (deep orange-yellow prisms, m. p. 162—163°); and 4-*carbethoxy*-2-*hydroxy*-5-*methylpyrrolidyl*-5′-*carbethoxy*-2′ : 4′-*dimethylpyrrylmethene*, needles, m. p. 266°.



Ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate couples with benzene-diazonium chloride to give a *dye*, $C_{14}H_{15}O_3N_3$ (glistening, pure yellow, felted needles, m. p. 233°), which forms a *sodium* salt, $C_{14}H_{14}O_3N_3Na$, red needles, and a *potassium* salt, orange-yellow needles. When treated with ammoniacal copper solution the dye is converted into an isomeric *compound* (large orange-red to dark red, transparent needles, decomposing at 213°), which on crystallisation from alcohol yields the original dye. The latter, when reduced with zinc dust in hot alcoholic solution or with hydrogen in presence of platinum black, yields ethyl 3-amino-2-hydroxy-5-methylpyrrole-4-carboxylate, m. p. 244° (cf. Fischer and Herrmann, A., 1922, i, 1054). *Dyes* obtained similarly from *m*-nitrobenzene-diazonium chloride and from α-naphthalene-diazonium chloride, form thin, yellow, bunched needles, m. p. 233°, and red needles, decomposing at 234°, respectively. The application of the Gattermann reaction to ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate yields, besides a *by-product* which decomposes at 262°, the *aldimine*, $C_9H_{12}O_3N_2$, colourless leaflets, m. p. 241°, which is not hydrolysed by water to the aldehyde, and is decomposed by alkalis with the liberation of ammonia. The *aldehyde*, however, may be obtained when sodium is added to a boiling mixture of ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate and ethyl formate, and forms large, flat needles, m. p. 206°. It yields a *semicarbazone*, bunched needles, m. p. 252° (with previous browning and sintering), and a *hydrazone*, small rods, m. p. 190°. It condenses with ethyl 3-hydroxy-5-methylpyrrole-4-carboxylate to yield 4-*carbethoxy*-3-*hydroxy*-5-*methylpyrrolidyl*-4′-*carbethoxy*-2′-*hydroxy*-5′-*methylpyrrylmethene*, yellow needles, m. p. 250°, and with ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate to yield bis-(4-*carbethoxy*-2-*hydroxy*-5-*methylpyrryl*)*methene*, brownish-yellow prisms, m. p. 254°. 4-*Carbethoxy*-3-*hydroxy*-5-*methylpyrrole*-2-*aldehyde*, faintly coloured needles, m. p. 188°, is obtained when ethyl 3-hydroxy-5-methylpyrrole-4-carboxylate is condensed with ethyl formate in presence of sodium. Ethyl oxalate, similarly, condenses with ethyl 2-hydroxy-5-methylpyrrole-4-carboxylate to form *ethyl* 4-*carbethoxy*-2-*hydroxy*-5-*methylpyrryl*-3-*glyoxylate*, glistening prisms, m. p. 180°, and with ethyl 3-acetyl-2 : 4-dimethylpyrrole-5-carboxylate to yield *ethyl* 5-*carbethoxy*-2 : 4-*dimethyl*-

pyrryl-3-ethanonoxalate, fine, colourless, felted needles, m. p. 150·5°. The latter is readily decomposed by alkalis to yield 3-acetyl-2 : 4-dimethylpyrrole-5-carboxylate, and forms a *semicarbazone*, m. p. 201°, and a *ketazine-hydrazide*, $C_{13}H_{17}O_3N_5$, needles, m. p. 239° (decomp.). Ethyl 2 : 4-dimethylpyrryl-3-ethanonoxalate forms a *semicarbazone*, m. p. 198° (decomp.). Ethyl 2 : 4-dimethylpyrrole-3 : 5-dicarboxylate, when heated with hydrazine hydrate at 200° in a closed tube, yields 2 : 4-dimethylpyrrole. If 1′-*p*-toluoyl-4-carbethoxy-3-hydroxy-5-methylpyrrolidyl-3′-carbethoxy-2′ : 5′-dimethylpyrrylmethene is treated with benzene-diazonium chloride, decomposition of that compound takes place simultaneously with coupling to give a mixture of 3-carbethoxy-2 : 5-dimethyl-1-*p*-toluylpyrrole-4-aldehyde and 2-benzeneazo-4-carbethoxy-3-hydroxy-5-methylpyrrole. W. O. K.

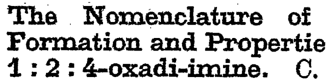
Oxidation–Reduction. IV. Electrode Potentials of Indigotinsulphonates. M. X. SULLIVAN, B. COHEN, and W. M. CLARK (*U.S. Public Health Repts.*, 1923, **38**, 1669—1718).—A survey of the literature shows conflicting statements regarding the behaviour of indigotin and its sulphonates in vitro and in vivo, and a lack of satisfactory theories due to lack of quantitative data for the oxidation–reduction equilibrium. Indigotin-mono-, -di-, -tri-, and -tetra-sulphonates were prepared by Bloxam's method (A., 1906, ii, 819), and the electrode potentials at 30° were determined by elaboration of methods already described (A., 1923, ii, 726, etc.). The experimental results were in accord with the rational equation : $E_h = E_o - [(RT/nF)\log_e(S_r/S_o)] + (RT/nF)\log_e[K_1(H^+) + (H^+)^2]$, where E_h is the observed electrode potential referred to the hydrogen standard, S_r and S_o are the concentrations of total reductant and total oxidant, (H^+) is the hydrogen-ion concentration of the solution, and K_1 the acid dissociation constant of one of the two hydrogen atoms of the hydrogenated leuco-compound (dissociation of the sulphonic acids not being considered). The number, *n*, of electrons in the reversible oxidation–reduction is 2. The second acidic hydrogen atom of the leuco-compound has a dissociation constant below 10^{-12}. The values of E_o and K_1 were as follows : indigotin-monosulphonate $\rightleftharpoons$ leuco-compound, +0·262, $1·6\times10^{-8}$; indigotin-disulphonate $\rightleftharpoons$ leuco-compound, +0·291, $4·9\times10^{8}$; indigotintrisulphonate $\rightleftharpoons$ leuco-compound, +0·332, $7·7\times10^{-8}$; indigotintetrasulphonate $\rightleftharpoons$ leuco-compound, +0·365, $11·2\times10^{-8}$. Indigotin $\rightleftharpoons$ indigo-white is not adapted to accurate experiments in aqueous solution. Approximate data indicate $K_1=10^{-8}$ and E_o near that of the monósulphonate. Anomalies with borate buffers are shown, and evidence is given of a " salt effect " with other buffer systems, of the acidic nature of the leuco-compounds, and of the ionisation of only one hydrogen atom at moderate alkalinities. An electrometric method of analysis of mixtures of the sulphonates is developed. The data cover all conditions for the reversible oxidation–reduction of an indigotinsulphonate and give their properties for use in colorimetric determinations of oxidation–reduction intensities of biological solutions. CHEMICAL ABSTRACTS.

Constitution of Isatan and Isatide. A. Wahl and W. Hansen (*Compt. rend.*, 1924, **178**, 393—396; cf. following abstract).—Isatan (I), $C_{16}H_{12}O_3N_2$, on heating in boiling naphthalene solution, affords indine (cf. Laurent, *Ann. Chim. Phys.*, 1840, [iii], **3**, 469); it results from the condensation of oxindole and isatin in presence of piperidine (cf. Stollé, A., 1914, i, 992), and is the product called isatide by Erdmann (*J. pr. Chem.*, 1840, [i], **24**, 1), who treated isatin with excess of ammonium hydrosulphide. Isatan was obtained by Laurent (*loc. cit.*) by reducing disulphoisatide with ammonium hydrogen sulphite. Isatide, $C_{16}H_{12}O_4N_2$ (II), which does not give indine on heating, is the product obtained by Laurent by treating isatin with a slight excess of ammonium hydrosulphide, and by Heller (A., 1904, i, 416) by reducing isatin with zinc and acetic acid. Isatide is formed rapidly when a mixture of dioxindole and isatin is treated, in alcoholic solution, with piperidine.

(I.) 
 (II).

E. E. T.

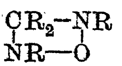
Transformation and Constitution of Disulphoisatide. A. Wahl and W. Hansen (*Compt. rend.*, 1924, **178**, 214—216).—The formula, $C_{16}H_{12}O_2N_2S_2$, given by Laurent (*Ann. Chim. Phys.*, 1840, [iii], **3**, 469) to disulphoisatide has been confirmed. The formation of indine by the action of alkali on disulphoisatide is shown to depend on the nature and concentration of the alkali used, and not to occur if air is excluded. The conversion is best effected by adding aqueous sodium carbonate to an aqueous-alcoholic solution of disulphoisatide. Isatin is produced simultaneously (55% of that obtainable on the basis of the equation : $2C_{16}H_{12}O_2N_2S_2 + 2H_2O = C_{16}H_{10}O_2N_2 + 4H_2S + 2C_8H_5O_2N$). Sulphur is initially formed, and reduces indine to leuco*iso*indigotin, which is oxidised if air is present. The annexed formula (cf. Kohn and Ostersetzer, A., 1916, i, 607, and Lefèvre, *ibid.*, 430) is proposed for disulphoisatide, a disulphide formula being excluded, since on reduction it gives leuco*iso*indigotin (A., 1923, i, 607). E. E. T.



The Additive Formation of Four-membered Rings. III. The Nomenclature of Four-membered Rings and the Formation and Properties of some Derivatives of Methylene-1 : 2 : 4-oxadi-imine. C. K. Ingold (*J. Chem. Soc.*, 1924, **125**, 87—102).—It has been found that the formation of a four-membered ring, by the additive union of double bonds (I) is of considerable generality, and this confirms the prediction (T., 1922, **121**, 2793) made from the analogy with the tautomeric change or internal addition reaction shown in (II):

(I.) 
 (II.)

A system of nomenclature is proposed for the new heterocyclic ring types that have been already produced. Part of the object of the work is to discover which of these types are the most stable. It has been shown earlier (*loc. cit.*, and T., 1923, **123**, 2745) that certain types of azomethines and nitroso-compounds pass into stable cyclic bimerides. It is now shown that an azomethine and a nitroso compound of the particular type combine additively to give a stable 1 : 2 : 4-oxadi-imine (annexed formula).



$\begin{array}{l}CR_2-NR\\ \,|\qquad\ \ |\\ NR-O\end{array}$

Methylene-p-*chloroaniline*, $CH_2{:}N{\cdot}C_6H_4Cl$, forms needles, m. p. 142°, the corresponding p-*bromo*-derivative, needles, having m. p. 169°. p-*Chloronitrosobenzene* has m. p. 90°, the corresponding *bromo*-derivative having m. p. 94°. The following compounds are also described: 2-*phenyl*-4-p-*tolylmethylene*-1 : 2 : 4-*oxadi-imine* (needles, m. p. 150°); the similar 4-p-*chlorophenylmethylene* compound (needles, m. p. 162°); the 4-p-*bromophenyl* compound (needles, m. p. 171°); 4-p-*chlorophenyl*-2-p-*tolylmethylene-oxadi-imine* (needles, m. p. 163°); the 4-p-*bromophenyl* derivative (m. p. 158°), the 2 : 4-*dichloro*-derivative (m. p. 171°), and the 2 : 4-*dibromo*-derivative (m. p. 175°). p-*Chlorophenylcarbylamine* forms needles (m. p. 71°), the corresponding *bromocarbylamine* having m. p. 99°. Both have an odour somewhat less powerful than that of phenylcarbylamine itself, but the taste of the vapour is considerably stronger. 2-p-*Chlorophenyl*-4-p-*bromophenylmethylene*-1 : 2 : 4-*oxadi-imine* forms needles, m. p. 171°.

Phenyl-p-*tolylcarbodi-imide*, $C_6H_4Me{\cdot}N{:}C{:}NPh$ (b. p. 170/12° mm.) (converted by aqueous-alcoholic hydrochloric acid into phenyl-*p*-tolylcarbamide), *phenyl*-p-*chlorophenylcarbodi-imide* (b. p. 175/11° mm.). p-*bromodiphenylcarbodi-imide* (b. p. 185/11° mm.), p-*chlorophenyl*-p-*tolylcarbodi-imide* (b. p. 175°/10 mm.), p-*bromophenyl*-p-*tolylcarbodi-imide* (b. p. 188°/10 mm.), pp′-*dichlorodiphenylcarbodi-imide* (b. p. 190°/10 mm.), pp′-*dibromodiphenylcarbodi-imide* (b. p. 202°/10 mm.), and p-*chloro*-p′-*bromodiphenylcarbodi-imide* (b. p. 198—200°/11 mm.) are, like the phenyl-*p*-tolyl derivative, viscous liquids, their constitutions being proved by conversion into the corresponding carbamides.

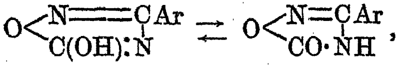
p-*Chlorophenyl*-p-*tolylcarbamide* (needles, m. p. 297—299° [decomp.]), p-*bromophenyl*-p-*tolylcarbamide* (needles, m. p. 316—318° [decomp.]), and p-*chloro*-p′-*bromodiphenylcarbamide* (needles, m. p. about 300° [decomp.]) were obtained (see *ante*) from the corresponding carbodi-imides. F. G. P.

The Additive Formation of Four-membered Rings. IV. The Influence of Temperature on the Tendency towards Self-addition of the Nitroso-group. C. K. INGOLD and H. A. PIGGOTT (*J. Chem. Soc.*, 1924, **125**, 168—176).—Owing to the chromophoric character of the nitroso-group, the use of the colorimeter enables the reversible reaction

$2\,\overset{|}{N}{:}O \rightleftharpoons \begin{array}{l}-N-O\\ \ \ |\qquad|\\ \ \ O-N-\end{array}$

to be followed in greater detail than is the case with the reactions previously studied (see preceding abstract). The influence of temperature on the equilibrium is determined for the case of nitrosomesitylene in benzene solution. Using these results, the order of the reaction is calculated from certain equations, and shown to be in accordance with the chemical evidence. Nitrosomesitylene, the preparation of which (and of mesidine) from dimethylaniline is described, has m. p. 122—123° (cf. Pechmann and Nold, A., 1898, i, 310). The heat absorbed during the dissociation of 1 g.-mol. of dimeric nitrosomesitylene is calculated to be about 13,700 g.-cal. In 3% solution in benzene, dissociation occurs to the extent of about 18%; in a 2% solution, 21·6%. This corresponds with a molecular weight 245, agreeing fairly well with Bamberger's value 246 obtained (A., 1901, i, 141) cryoscopically in benzene solution. F. G. P.

Dioximes. XVII. G. PONZIO and B. ZANARDI-LAMBERTI (*Gazzetta*, 1923, **53**, 818—824).—In some of their properties, 5-hydroxy-3-aryl-1 : 2 : 4-oxadiazoles (or hydroxyazoximes),



$$O<\begin{matrix}N{=\!=}CAr\\ C(OH){:}N\end{matrix} \rightleftharpoons O<\begin{matrix}N{=}CAr\\ CO\cdot NH\end{matrix},$$

which are formed by withdrawal of two atoms of hydrogen from the α-modifications of monoarylglyoximes, differ considerably from the 3 : 5-diaryl-1 : 2 : 4-oxadiazoles (or azoximes), which result on elimination of a molecule of water from a *s*-diarylglyoxime. Thus, the azoximes are either completely destroyed or slowly converted into nitriles by the action of reducing agents, whereas the hydroxyazoximes are very easily reduced to amidines, $NH_2{\cdot}CR{:}NH$, by means of hydriodic acid in presence of red phosphorus. Further, the hydroxyazoximes exhibit acid properties, the mean values of the ionisation constant at 25° being $0{\cdot}879\times10^{-5}$, $0{\cdot}022\times10^{-5}$, and $0{\cdot}140\times10^{-5}$ for 5-hydroxy-3-phenyl-, *p*-tolyl-, and benzyl-1 : 2 : 4-oxadiazoles; thus, the *p*-tolyl compound is slightly weaker than carbonic acid, and the other two compounds are stronger.

Benzenylamidine, obtained by reduction of 5-hydroxy-3-phenyl-1 : 2 : 4-oxadiazole, gives a picrate, m. p. 235°; Dieckmann (A., 1892, 705) gave m. p. 228°. According to Pinner ("Die Imidoaether," 167), 2 : 4 : 6-triphenyl-1 : 3 : 5-triazine is formed when benzenylamidine hydrochloride is heated for six hours at 120—140° with benzoyl chloride. This reaction occurs at the ordinary temperature when benzenylamidine carbonate is treated with 20% sodium hydroxide solution and benzoyl chloride.

5-Hydroxy-3-*p*-tolyl-1 : 2 : 4-oxadiazole, prepared from *p*-tolenylamidoxime and ethyl chlorocarbonate (cf. Schubart, A., 1890, 47), is the product of the isomerisation of the oxide of *p*-tolyl cyanide oxime (cf. Avogadro, this vol., i, 294). By hydriodic acid and red phosphorus it is converted into *p*-tolenylamidine, which forms a *picrate*, $C_6H_4Me{\cdot}C({:}NH){\cdot}NH_2,C_6H_3O_7N_3$, crystallising in yellow needles, m. p. 224—225° (decomp.), and a *carbonate*, crystallising in white laminæ, m. p. 127—128° (gas); the corresponding nitrate was described by Pinner (*loc. cit.*, 184). 5-Hydroxy-3-*p*-tolyl-1 : 2 : 4-oxadiazole forms the following derivatives: *sodium* salt, white powder; *silver* salt, white crystals, stable towards light; *methyl ether*, slender, white needles.

5-*Hydroxy*-3-*benzyl*-1 : 2 : 4-*oxadiazole*, $$O<\begin{matrix}N{=\!=\!=}C\cdot CH_2Ph\\ C(OH){:}N\end{matrix}$$
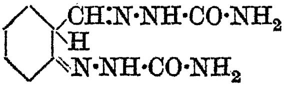
, prepared by the action of sodium hydroxide on the ethyl phenylethenylamidoximecarboxylate obtained by the interaction of ethyl chlorocarbonate and phenylethenylamidoxime, $CH_2Ph\cdot C(:NOH)\cdot NH_2$, crystallises in large, lustrous laminæ, m. p. 115°. By hydriodic acid and red phosphorus it is converted into phenylethenylamidine, $CH_2Ph\cdot C(:NH)\cdot NH_2$, the *picrate* of which forms yellow needles, m. p. 224° (decomp.). 5-Hydroxy-3-benzyl-1 : 2 : 4-oxadiazole forms a *sodium* salt, white powder; an insoluble *silver* salt, white, crystalline powder, stable towards light, and a *methyl ether*, crystallising in needles, m. p. 112—113°.

5-Hydroxy-3-α-naphthenyl-1 : 2 : 4-oxadiazole has m. p. 196°, and not 189° as stated by Richter (A., 1890, 62). α-*Naphthenylamidine*, $C_{10}H_7\cdot C(:NH)\cdot NH_2$, crystallises in white laminæ, m. p. 154°, and its *picrate* in yellow needles, m. p. 223° (decomp.).

5-Hydroxy-3-β-naphthenyl-1 : 2 : 4-oxadiazole, m. p. 219—220° (Richter, *loc. cit.*, gave 216°), yields on reduction β-naphthenylamidine, the *picrate* of which forms reddish-yellow needles, m. p. 240° (decomp.). T. H. P.

Tetrahydroindazoles. K. von Auwers, W. Buschmann, and R. Heidenreich (*Annalen*, 1924, **435**, 277—321).—A study of the tetrahydroindazoles obtained by condensing hydrazine derivatives with hydroxymethylene*cyclo*hexanone and 1-methyl-3-hydroxymethylene*cyclo*hexan-2-one. In the preparation of the latter compound (cf. A., 1915, i, 818), acetone sodium (Freer, A., 1894, i, 65) and 1-methyl*cyclo*hexan-2-ol are formed as by-products. 1-*Methyl*-3-*benzoxymethylene*cyclo*hexan*-2-*one* (needles, m. p. 84—85°) is hydrolysed more readily by acids than by alkalis.

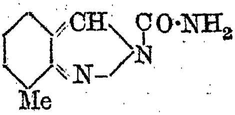
Semicarbazide reacts with hydroxymethylene*cyclo*hexanone to give tetrahydroindazole-2-carbonamide (Wallach and Steindorff, A., 1904, i, 104), the constitution of which is now definitely established by its formation by the hydrolysis of the *semicarbazone* of benzoxymethylene*cyclo*hexanone (needles, m. p. 193° if bath previously heated at 190°). Excess of semicarbazide converts the hydroxymethylene ketone into the *disemicarbazone* (I), which in hot dilute sulphuric acid solution affords the above carbonamide. The latter, as shown by Wallach (*loc. cit.*) occurs in two forms, although the latter author's m. p. observations are incorrect. The carbonamide, if obtained in the labile form (as in the first method given above), has m. p. 158°, but unless the m. p. bath is previously heated to within a few degrees of this temperature, the labile form passes, before its m. p. is reached, into the stable form (m. p. 186—188°) (see *infra*). Wallach's second m. p. (220°) actually indicated the decomposition of the carbonamide to give cyanuric acid.

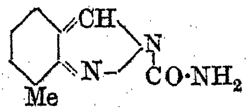


(I.)

The above disemicarbazone (I) had m. p. 193° when first prepared, but after six months, m. p. 203°. The lower m. p. is that of the labile form, which was not subsequently obtained. The substance becomes solid after melting at 203°, re-melting, with decomposition, at 234—236°.

Methyl-hydroxymethylene*cyclo*hexanone affords (with semicarbazide in cold acetic acid solution) the normal *semicarbazone* (white needles, m. p. 193° or 203°, according to the rate of heating), the *benzoyl* derivative of the latter being identical with the *semicarbazone* (m. p. 186°) of methyl-benzoxymethylene*cyclo*hexanone. Excess of semicarbazide converts the methyl hydroxymethylene ketone into the *disemicarbazone* (prisms, m. p. 215° if heated suddenly, and 237° [decomp.]), together with a little 7-*methyltetrahydroindazole*-2-*carbonamide*, the latter also being formed in small quantities in the preparation of the monosemicarbazone. The carbonamide exists in two forms: *labile* form, monoclinic needles, m. p. 138° (if plunged suddenly into bath just below 138°), then solidifying to give the *stable* form, tetragonal crystals, m. p. 163°. The labile form can be kept at the ordinary temperature, but passes into the stable form on heating in a toluene vapour-bath, or on boiling in alcoholic solution. The labile form results when the semicarbazone is treated in cold acetic acid solution with a little sulphuric acid, with subsequent addition of water, whereas if the solution is heated before addition of water, the latter precipitates the stable form. Again, when the parent ketone is treated with semicarbazide in presence of mineral acid, the carbonamide is formed, the production of the labile or of the stable form depending on the hydrogen-ion concentration. The carbonamide is converted by ammoniacal silver nitrate solution into the *silver* salt of 7-methyltetrahydroindazole, this salt, with carbamyl chloride, affording a mixture of the two forms of the carbonamide. The latter are shown to be stereoisomerides (see annexed formulæ), and not structural isomerides. They are readily interconvertible; moreover, under conditions when a 1-derivative might be expected to result (as when the parent ketone is treated with semicarbazide hydrochloride), the labile form, already proved to be a 2-derivative, is obtained. Polymorphism is also excluded as an explanation of the isomerism, on experimental grounds.





Tetrahydroindazole (m. p. 84°), first obtained by Wallach (*loc. cit.*), is prepared by boiling tetrahydroindazole-2-carbonamide (or the parent semicarbazones) with mineral acids, and gives the following derivatives: *picrate*, m. p. 155—156°; *silver* salt; 2-*acetyl* derivative, b. p. 130°/15 mm.; and 2-o-*nitrobenzoyl* derivative, white needles, m. p. 129—130°.

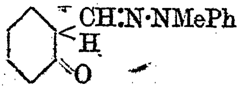
7-*Methyltetrahydroindazole* is a viscous oil, b. p. 152·8°/12 mm., becoming solid at the temperature of mixtures of ether and solid carbon dioxide. The following derivatives are described: *hydrochloride*, white prisms; *picrate*, m. p. 151—152°; *mercuric chloride additive* compound, white needles; *silver nitrate additive* compound, $Ag(C_8H_{12}N_2)_2NO_3$, white needles, m. p. 132°; *silver* salt, $C_8H_{11}N_2Ag$ (two forms, one soluble and one insoluble in ether); 2-*phenyl*-

carbonamide, white prisms, m. p. 70° (from the indazole and phenylcarbimide); and 2-o-*nitrobenzoyl* derivative, leaflets, m.p. 104—107°. The parent indazole is obtained either by treating methyl-hydroxymethylene*cyclo*hexanone semicarbazone with hot dilute sulphuric acid, or the ketone itself with hydrazine.

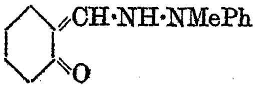
Hydroxymethylene*cyclo*hexanone, when treated with phenylhydrazine, gives a mixture of 1- and 2-phenyltetrahydroindazoles, which are not interconvertible and are separable as the picrates. The constitution of the 2-phenyl derivative follows from its formation from the benzoylated ketone and phenylhydrazine. The intermediately formed *phenylhydrazone* of the benzoylated ketone has only a transitory existence (white needles, m. p. about 80°), and rapidly passes into the above 2-phenylindazole derivative. 1-*Phenyl*-4 : 5 : 6 : 7-*tetrahydroindazole* forms leaflets, m. p. 58—59°, b. p. 178°/10 mm. (*picrate*, m. p. 125—126°, and *perchlorate* are described). 2-*Phenyltetrahydroindazole* forms prisms, m. p. 48·5—49·5°, b. p. 177°/10 mm. (*picrate*, m. p. 126·5—127·5°, and *perchlorate* are described).

In the interaction of hydroxymethylene*cyclo*hexanone and phenylhydrazine, the higher the concentration of hydrion, the smaller the proportion of 2-phenyl derivative formed, particularly if, at the same time, the temperature is kept low. Thus, when the ketone is treated at 0° with phenylhydrazine hydrochloride, only the 1-phenyl derivative is formed. This is explained as being due to the driving back, by hydrion, of the dissociation of the hydroxymethylene group, with resulting increase in the proportion of the aldehydic form, from which the 1-compound would be formed (cf. Claisen, A., 1895, i, 62). In this connexion, the nature of the hydrazine derivative affects the proportion of 1- to 2-derivative obtained, this being, under comparable conditions, as follows: phenylhydrazine, 1 : 0, *as*-phenylmethylhydrazine, 2 : 1, benzylhydrazine, 3 : 4, methylhydrazine, 4 : 1, and semicarbazide, 0 : 1.

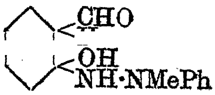
In order to throw light on the constitution of the intermediate compounds formed in the interaction of phenylhydrazine and hydroxymethylene*cyclo*hexanone, the interaction of the latter with phenylmethylhydrazine has been studied. The main product (m. p. 170—171°) is insoluble in alkali and may be either the *phenylmethylhydrazone* of 2-*keto*cyclo*hexylformaldehyde* (II) or 1-*methylphenylhydrazidomethene*cyclo*hexan*-2-*one* (III). A second product, soluble in alkali, is the *hydrate* (needles, m. p. 123—124°) of the *acid* produced by the spontaneous oxidation of IV. There is also formed a third product (under slightly different conditions), viz., the *hydrate* of the *phenylmethylhydrazone* of 1-*formyl*cyclo*hexan*-2-*one* (needles, m. p. 125—126°).



(II.)



(III.)



(IV.)

Methyl-hydroxymethylene*cyclo*hexanone, with phenylhydrazine, affords a mixture of the 1- and 2-indazole derivatives, low temperatures and high concentrations favouring the production of the 1-derivative. The latter is a stronger base than the 2-derivative, and forms a stable *perchlorate* (m. p. 214—215°), which allows of its separation from its isomeride. The benzoyl derivative of the methyl*cyclo*hexanone affords a *phenylhydrazone* (m. p. 125°, with previous sintering), which rapidly passes, in solution, into 2-*phenyl-7-methyl-*4 : 5 : 6 : 7-*tetrahydroindazole* (a colourless oil, b. p. 181·4°/10 mm. The *methiodide*, m. p. 172°, gives 2-phenyltetrahydroindazole when heated). 1-*Phenyl-*7-*methyltetrahydroindazole* is a colourless oil, b. p. 175°/10 mm.; its *methiodide*, m. p. 154°, on heating, gives 1-phenyltetrahydroindazole.

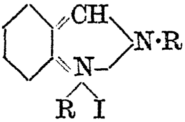
The products of the alkylation of tetrahydroindazole depend on the nature of the alkyl group introduced and on the experimental conditions. Tetrahydroindazole, when heated in alcoholic solution with benzyl chloride in presence of alkali, or when heated alone with the chloride at water-bath temperatures, affords a mixture of the 1- and 2-benzyl derivatives, this mixture also being obtained by condensing benzylhydrazine with hydroxymethylene*cyclo*hexanone. The benzoyl derivative of the latter ketone is converted by benzylhydrazine into 2-*benzylindazole* (colourless oil, b. p. 177°/10 mm.). 1-*Benzyltetrahydroindazole* is a colourless oil, b. p. 172°/10 mm. (*picrate*, m. p. 128—129°, and *perchlorate* are described).

Tetrahydroindazole, when heated at 100° with ethyl bromide, gives 2-*ethyltetrahydroindazole* (a colourless oil, b. p. 118°/15 mm.; *picrate* has m. p. 150·5—151·5°), whilst when similarly heated in presence of alkali, it affords 1-*ethyltetrahydroindazole* (a colourless oil, b. p. 111°/14 mm.; *picrate* has m. p. 103—104°).

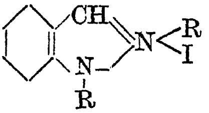
The methylation of tetrahydroindazole leads, in presence or in absence of alkali, to the formation of the 1- and 2-methyl derivatives, which cannot be separated. 2-*Methyltetrahydroindazole*, obtained from benzoxymethylene*cyclo*hexanone, is a colourless oil, b. p. 93—94°/9 mm. or 103°/13 mm. (*picrate*, m. p. 166·5—167·5°).

7-Methyltetrahydroindazole on methylation, ethylation, or benzylation, in presence or in absence of alkali, always affords 2-derivatives, which may be obtained from the appropriate hydrazine and methylbenzoxymethylene*cyclo*hexanone. 2 : 7-*Dimethyl-*4 : 5 : 6 : 7-*tetrahydroindazole* is a colourless oil with a feeble blue fluorescence, has b. p. 111°/13 mm., and forms a *picrate*, m. p. 123—125°. 7-*Methyl-2-ethyltetrahydroindazole*, a colourless oil, b. p. 108·5°/10 mm., gives a *picrate*, m. p. 101—102°, and a *methiodide*, m. p. 102—103°, the latter affording 7-methyl-2-ethyltetrahydroindazole when heated. 7-*Methyl-*2-*benzyltetrahydroindazole*, a colourless oil, b. p. 181—183°/12 mm. or 152°/3 mm., forms a *methiodide* (leaflets, m. p. 175° [decomp.]), which is also obtained from 2 : 7-dimethyltetrahydroindazole and benzyl iodide, and, on heating, affords the two last-named substances. The fact that the 7-methyl group prevents alkylation in position 1 is to be ascribed to electrochemical (not stereochemical) effects (cf. attempts to prepare 1 : 5-dialkylpyrazoles by Auwers and Broche, A., 1923, i, 151).

The formation of quaternary salts from the reduced indazoles is not altogether parallel to their formation in the ordinary series. The 2-methyl- and 2-ethyl-tetrahydroindazoles follow the general rule. Methyl iodide converts either 1- or 2-methyltetrahydroindazole into 1 : 2-*dimethyl*-4 : 5 : 6 : 7-*tetrahydroindazolium iodide* (m. p. 152—153°). Ethyl iodide converts either 1- or 2-ethyltetrahydroindazole into 1 : 2-*diethyltetrahydroindazolium iodide* (m. p. 98—99°). Since these quaternary salts afford mixtures of 1- and 2-alkyl derivatives when heated, they are given formulæ V or VI, or, better, VII :



(V.)



(VI.)

$[C_6H_8{\cdot}CH(N^2R)(N^1R)]I.$

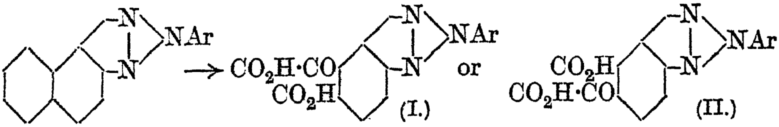
(VII.)

2-Benzyltetrahydroindazole, when heated with ethyl iodide, affords the *compound* (m. p. 138—139°) obtained by heating 2-ethyltetrahydroindazole with benzyl iodide. The compound, on heating, affords pure 2-ethyltetrahydroindazole, and therefore is written as $[C_6H_8{\cdot}CH(N^2Et[Ph{\cdot}CH_2{\cdot}])(N^1)]I$, both alkyl groups being attached to the same nitrogen atom. Similarly, the *compound*, $[C_6H_8{\cdot}CH(N^2)(N^1Et[Ph{\cdot}CH_2{\cdot}])]I$ (m. p. 127—128°), is formed from 1-benzyltetrahydroindazole and ethyl iodide or from the 1-ethyl derivative and benzyl iodide. The 1 : 1-quaternary salt, on heating, affords, not 1-ethyl-, but 2-ethyl-tetrahydroindazole.

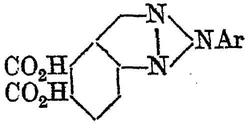
7-Methyltetrahydroindazole gives quaternary salts in which the two alkyl groups are attached to the same nitrogen atom (see *ante*). The *methiodides* of 1- and 2-phenyltetrahydroindazoles afford, when heated, the parent phenyl derivatives.

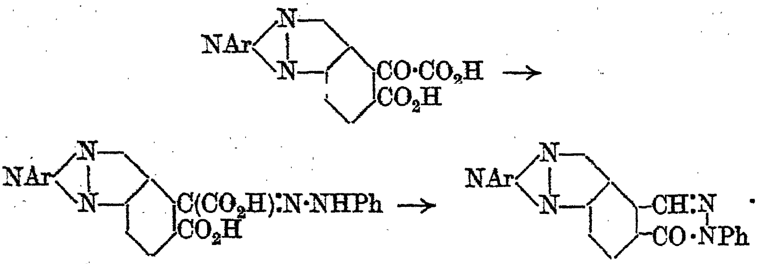
7-Methyltetrahydroindazole reacts with ethyl bromoacetate to give *ethyl* 7-*methyl*-4 : 5 : 6 : 7-*tetrahydroindazyl*-2-*acetate* (colourless oil, b. p. 166·5—167·5°/14 mm.; *picrate*, m. p. 127—130° [indef.]). The corresponding *acid* (also obtainable from the indazole and chloroacetic acid), obtained by hydrolysis, forms white needles, m. p. 168—169° (*silver* salt described), and has, unlike the indazole bases, a sweet taste. E. E. T.

***vic.*-2 : *N*-Aryltriazolephthalonic Acids.** G. CHARRIER (*Gazzetta*, 1923, **53**, 829—843).—It has been shown by Dimroth (A., 1902, i, 403) that, starting from the three isomeric *N*-phenyl derivatives of 1 : 2 : 3-triazolemonocarboxylic acid and eliminating the phenyl group by oxidation after nitrating and converting into the amino-derivative by reduction, one and the same acid is obtained; the desmotropy of the triazole ring is thus established. Oxidation of naphthalene by means of alkaline permanganate solution yields mainly phthalonic acid, and the author finds similarly that the 2-arylnaphthatriazoles give, under the same conditions, principally the corresponding vicinal 2-aryltriazolephthalonic acids,



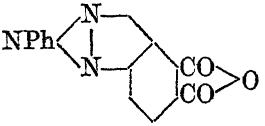
Since these acids are highly stable towards oxidising agents and are prone to form monometallic salts with the alkali metals, probably owing to the formation of an internal anhydride between the $\cdot CO\cdot CO_2H$ group and the triazole ring, and further on account of the analogy existing between them and the product of the oxidation of naphthalic acid by permanganate in alkaline solution (cf. Graebe and Bossel, A., 1893, i, 593), formula (I) is regarded as preferable to formula (II). The constitution of these acids is shown also by their oxidation to the corresponding 2-aryltriazolephthalic acids (annexed formula), and by their ability to react as keto-acids, analogously to phthalonic acid, with phenylhydrazine hydrochloride to form phenylhydrazones. The latter are far more stable than those of phthalonic acid, since only by heating above their melting points are they transformed, like phenylhydrazones of a keto-acid, into derivatives of the corresponding ketotetrahydropyridazines (pyridazinones); a carboxyl group is eliminated at the same time, so that from a dibasic acid a neutral heterocyclic derivative is obtained:





These acids behave as comparatively strong dibasic acids; they decompose carbonates, form well crystallised salts containing water of crystallisation, and readily yield normal and acid esters and amides. When subjected to prolonged energetic oxidation, they give the corresponding phthalic acids.

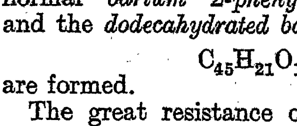
[With A. Odifreddi, A. Manfredi, and E. Mars.]—vic.-2-*Phenyltriazolephthalonic acid*, $C_{15}H_9O_5N_3$, obtained by oxidising 2-phenylnaphthatriazole, crystallises in white or lustrous needles, m. p. 242°, and has an intense acid reaction towards litmus, methyl orange and phenolphthalein. It yields the following derivatives: *monosodium* salt, $C_{15}H_8O_5N_3Na,4H_2O$, m. p. 324—325°, gives aqueous solutions acid to litmus and phenolphthalein. The normal



barium salt crystallises with $4H_2O$ and also with $5H_2O$, and when subjected to dry distillation in the anhydrous state yields vic.-2-*phenyltriazolephthalic anhydride* (annexed formula), which crystallises in slender, white needles, m. p. 183—184°, and, when treated with *m*-diethylaminophenol and zinc chloride, gives a deep red, crystalline colouring matter; the hydrochloride of the latter dissolves in boiling alcohol to an intense reddish-violet, markedly fluorescent solution, and crystallises in slender, metallic green needles similar to the crystals of rhodamine base B hydrochloride. *Basic barium 2-phenyltriazolephthalonate,*  $\left[PhN_3{:}C_6H_2<{}^{CO\cdot CO_2}_{CO_2}>Ba\right]_3,Ba(OH)_2,12H_2O$, forms rosettes of slender, silky needles and decomposes before melting. The *strontium* salt, $C_{15}H_{17}O_5N_3Sr,4\frac{1}{2}H_2O$, forms lustrous, white needles and decomposes before melting. The *methyl* ester, $C_{13}H_7ON_3(CO_2Me)_2$, forms minute, white prisms, m. p. 87—88°, and the *methyl hydrogen* ester, $C_{16}H_{11}O_5N_3$, colourless, prismatic crystals, m. p. 201—202°. The *ethyl* ester crystallises in colourless prisms, m. p. 169—170°. The *diamide*, $C_{13}H_7ON_3(CO\cdot NH_2)_2$, forms lustrous, colourless prisms, m. p. 233—234°, and, when boiled with 10% ammonia solution, yields the *ammonium* salt of the *monoamide*, $C_{15}H_{13}O_4N_5$, which crystallises in slender, white needles, m. p. 250° (decomp.). The *phenylhydrazone*, probably

$$Ph\cdot N_3{:}C_6H_2(CO_2H)\cdot C(CO_2H){:}N\cdot NHPh,$$

crystallises in white, silky needles, m. p. 206—207° (decomp.), and acts as an energetic acid.



The monocarboxylic ketotetrahydropyridazinic acid, that is, the pyridazinone of *vic.*-2-phenyltriazolephthalonic acid, is not formed when the phenylhydrazone is boiled in acetic acid, but when heated at 250° the phenylhydrazone loses carbon dioxide and water, to give the decarboxylated *pyridazinone* (annexed formula), which crystallises in colourless prisms, m. p. about 200°. When the phenylhydrazone is treated in boiling water with barium carbonate, phenylhydrazine separates and the pentahydrated normal *barium 2-phenyltriazolephthalonate*, $C_{15}H_7O_5N_3Ba,5H_2O$, and the *dodecahydrated basic barium* salt,

$$C_{45}H_{21}O_{15}N_9Ba_3,Ba(OH)_2,12H_2O,$$

are formed.

The great resistance offered by *vic.*-2-phenyltriazolephthalonic acid to oxidising agents may be due to the existence of an anhydridic linking between the triazole nucleus and the $\cdot CO\cdot CO_2H$ group, which is thus protected from the action of nascent oxygen. The acid is, however, attacked by chromic acid with formation of a *compound* which crystallises in aggregates of radiating leaflets, m. p. 250°, acts as an energetic acid, and has the nitrogen content of a *vic.*-2-phenyltriazolephthalic acid.

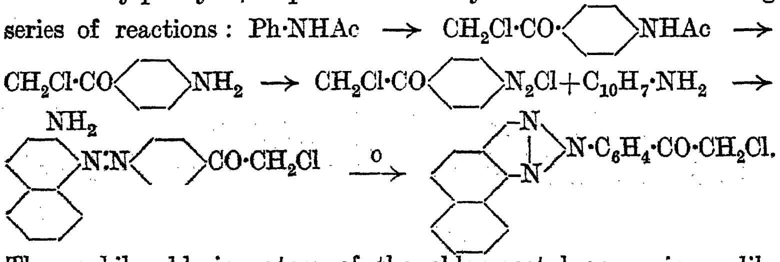
vic.-2-p-*Chlorophenyltriazolephthalonic acid*,
$C_6H_4Cl\cdot N_3\colon C_6H_2(CO_2H)\cdot CO\cdot CO_2H$,
crystallises in slender, white needles, m. p. 264—265°; its *monosodium* salt ($+2H_2O$) does not melt at 360°.

2-p-*Bromophenylnaphthatriazole*, $C_{10}H_6\cdot N_3\cdot C_6H_4Br$, prepared by oxidising *p*-bromophenylazo-β-naphthylamine by means of chromic acid in acetic acid solution, crystallises in white, silky needles, m. p. 200°.

vic.-2-p-*Bromophenyltriazolephthalonic acid*, obtained by the action of alkaline permanganate solution on the preceding compound, forms flat, white needles, m. p. 270°; its *monosodium* salt ($+2H_2O$) does not melt at 320°.

vic.-2-p-*Carboxyphenyltriazolephthalonic acid*, $C_{16}H_9O_7N_3$, crystallises in slender, white needles, m. p. 287—288° (decomp.), and is an energetic tribasic acid; its *monosodium* salt ($+4\frac{1}{2}H_2O$) does not melt at 350°.
T. H. P.

αβ-Naphthatriazoles. G. Charrier and M. Gallotti (*Gazzetta*, 1923, **53**, 851—861).—The authors have prepared 2-*p*-chloroacetylphenyl-αβ-naphthatriazole by means of the following series of reactions :



The mobile chlorine atom of the chloroacetyl group is readily replaced, giving the corresponding iodo- and cyano-derivatives. Hydrolysis of the latter gives the unstable ketonic acid, which loses carbon dioxide to form the corresponding ketone, 2-*p*-acetylphenyl-αβ-naphthatriazole. Treatment of the chloroacetyl compound with silver acetate yields the acetyl derivative of the corresponding ketocarbinol, αβ-naphthatriazole-2-*p*-benzoylcarbinol, which may be obtained either by hydrolysis of the acetyl derivative or by the action of moist silver oxide on the chloroacetyl compound itself. The latter reacts normally with ammonia, yielding αβ-naphthatriazole-2-*p*-benzoylmethylamine, whilst with primary aliphatic amines both substitution and addition occur, the unstable compound thus formed losing water and alkylamine when treated with an acid or even with a solvent :

$$C_{10}H_6\colon N_3\cdot C_6H_4\cdot CO\cdot CH_2Cl \longrightarrow C_{10}H_6\colon N_3\cdot C_6H_4\cdot CO\cdot CH_2\cdot NHR,xNH_2R$$
$$\longrightarrow C_{10}H_6\colon N_3\cdot C_6H_4\cdot C(\colon NR)\cdot CH_2\cdot NHR;$$

the resulting compound consists of the corresponding 2-*p*-β-alkylamino-α-alkyliminoethylphenyl-αβ-naphthatriazole. Aniline acts similarly to ammonia, the chlorine atom of the *p*-chloroacetyl group being replaced by the anilino residue.

[With R. SALA, Q. MINGOIA, and P. TORAZZI.]—p-*Chloroacetylbenzeneazo-β-naphthylamine*, $NH_2\cdot C_{10}H_6\cdot N{:}N\cdot C_6H_4\cdot CO\cdot CH_2Cl$, crystallises in thin, lustrous, garnet-red leaflets, m. p. 172°, and dissolves in concentrated sulphuric acid to a magenta-red solution. Its *phenylhydrazone* forms a red, crystalline powder with metallic green reflex, m. p. 180° (decomp.).

2-p-*Chloroacetylphenyl-αβ-naphthatriazole*,

$$C_{10}H_6<\overset{N}{\underset{N}{|}}>N\cdot C_6H_4\cdot CO\cdot CH_2Cl,$$

prepared by oxidising the preceding compound by means of chromic acid, forms thin, white leaflets, m. p. 198°, and dissolves in concentrated sulphuric acid to a yellow solution. Its *phenylhydrazone* crystallises in thin, pale yellow leaflets, m. p. 156°.

2-p-*Iodoacetylphenyl-αβ-naphthatriazole* separates in lustrous, white needles, m. p. 195°.

2-p-*Cyanoacetylphenyl-αβ-naphthatriazole*, $C_{19}H_{12}ON_4$, crystallises in slender, yellow needles, m. p. 185°, with previous contraction, and, on protracted boiling with 50% sulphuric acid, gives 2-*p*-acetylphenyl-αβ-naphthatriazole (cf. A., 1922, i, 771).

αβ-*Naphthatriazole*-2-p-*benzoylcarbinol*,

$$C_{10}H_6<\overset{N}{\underset{N}{|}}>N\cdot C_6H_4\cdot CO\cdot CH_2\cdot OH,$$

crystallises in silvery leaves, m. p. 191°, and its *acetyl* derivative in slender, white needles, m. p. 187°.

αβ-*Naphthatriazole*-2-p-*benzoylmethylamine*,

$$C_{10}H_6<\overset{N}{\underset{N}{|}}>N\cdot C_6H_4\cdot CO\cdot CH_2\cdot NH_2,$$

forms minute, almost colourless crystals, m. p. 192°, and gives a pale yellow *hydrochloride*, m. p. 184°.

2-p-β-*Methylamino-α-methyliminoethylphenyl-αβ-naphthatriazole*,  $C_{10}H_6<\overset{N}{\underset{N}{|}}>N\cdot C_6H_4\cdot C({:}NMe)\cdot CH_2\cdot NHMe$, crystallises in yellow needles, m. p. 160°, and forms a yellowish-brown hydrochloride.

2-p-β-*Ethylamino-α-ethyliminoethylphenyl-αβ-naphthatriazole*, $C_{22}H_{23}N_5$, separates in slender, pale yellow needles, m. p. about 150° with previous contraction.

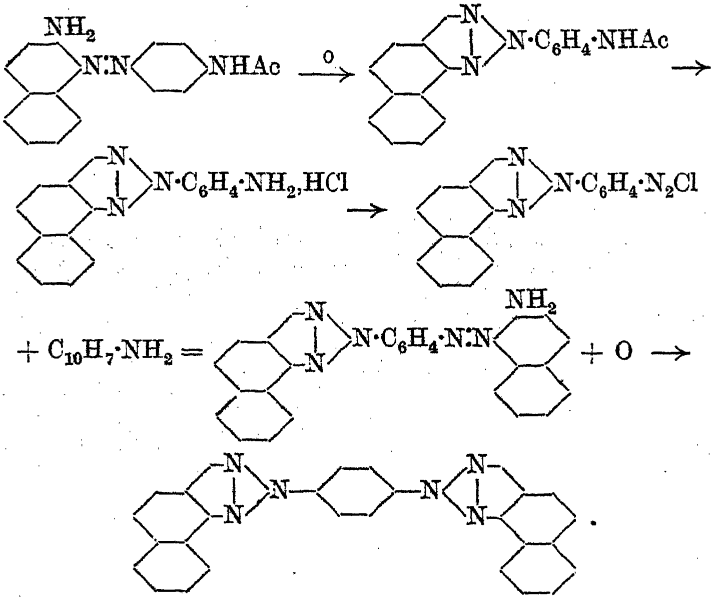
αβ-*Naphthatriazole*-2-p-*benzoylmethylaniline*,

$$C_{10}H_6<\overset{N}{\underset{N}{|}}>N\cdot C_6H_4\cdot CO\cdot CH_2\cdot NHPh,$$

crystallises in lustrous, sulphur-yellow leaflets, m. p. 277°, and forms benzene solutions exhibiting pronounced greenish-yellow fluorescence; its *phenylhydrazone* separates in slender, lemon-yellow needles, m. p. about 270° (decomp.). T. H. P.

Oxidation of Uric Acid by Iodine in Alkaline Solution. J. MORE (*Compt. rend.*, 1924, **178**, 498—501).—Oxidation of uric acid (1 mol.) by iodine (2 atoms), in potassium hydrogen carbonate solution, affords a substance (not isolated), which is converted by acetic acid into allantoin, and (cf. Biltz and Max, A., 1921, i, 893) is further oxidisable by iodine in acid solution. Oxidation of uric acid by means of iodine in sodium hydroxide solution (cf. Kreidl, A., 1893, ii, 558) gives first a substance which affords a uroxanate on evaporation in alkaline solution, or allantoin on evaporating in acetic acid solution, and in presence of alkali may also pass into a less readily oxidised isomeride. The latter, however, yields the same products as above, on evaporation in alkaline or acid solution, and on oxidation with iodine gives *allantoxalic amide*. The latter, when treated with concentrated potassium hydroxide, affords potassium allantoxalate; the following *salts* are described: $C_4H_3O_3N_4K,1{\cdot}5H_2O$; $C_4H_3O_3N_4Na,1{\cdot}5H_2O$, and $C_4H_3O_3N_4(NH_4),H_2O$. E. E. T.

p-Phenylene-1:2-dinaphthaditriazole. G. CHARRIER (*Gazzetta*, 1923, **53**, 862—867).—This compound has been prepared by means of the following series of reactions: $C_6H_5{\cdot}NHAc \longrightarrow NO_2{\cdot}C_6H_4{\cdot}NHAc \longrightarrow NH_2{\cdot}C_6H_4{\cdot}NHAc \longrightarrow N_2Cl{\cdot}C_6H_4{\cdot}NHAc + C_{10}H_7{\cdot}NH_2 \longrightarrow$



It is a highly stable compound and, as is usual with αβ-naphthatriazoles, is oxidised by permanganate in alkaline solution, giving *vic.-p*-phenyleneditriazolediphthalonic acid. Derivatives of the *p*-phenylene-1:2-dinaphthaditriazole have not previously been prepared (cf. Morgan and Chazan, A., 1922, i, 181). It is found possible to pass directly, by oxidation by means of alkaline permanganate solution, from 1:2-naphthatriazole-2-*p*-benzeneazo-β-naphthylamine to the above diphthalonic acid, preparation of the corresponding naphthatriazole as an intermediate product being unnecessary. Similarly, *vic.*-2-phenyltriazolephthalonic acid may be prepared directly from 1-benzeneazo-2-naphthylamine.

[With G. BONOMI and T. BETTINAZZI.]—*p*-Acetylaminobenzeneazo-β-naphthylamine, $C_{18}H_{16}ON_4$, prepared by the interaction of *p*-acetylaminophenyldiazonium chloride and β-naphthylamine in alcoholic solution, crystallises in slender, orange-red needles, m. p. 208°.

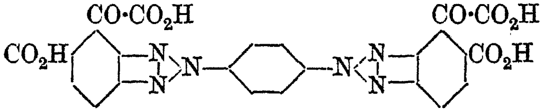
2-p-*Acetylaminophenyl*-1 : 2-*naphthatriazole*, $C_{18}H_{14}ON_4$, obtained by oxidising the preceding compound in acetic acid solution by means of chromic acid, forms slender, white needles, m. p. 228°, and exhibits marked blue fluorescence even in very dilute solutions.

2-p-*Aminophenyl*-1 : 2-*naphthatriazole*, $C_{16}H_{12}N_4$, crystallises in lustrous, silky, white needles, m. p. 200°.

1 : 2-*Naphthatriazole*-p-*benzeneazo*-β-*naphthylamine*, $C_{26}H_{18}N_6$, separates in bright red needles, m. p. 250°.

p-*Phenylene*-1 : 2-*dinaphthaditriazole*, $C_{26}H_{16}N_6$, forms thin, pink laminæ, m. p. 333°.

vic.-p-*Phenyleneditriazolediphthalonic acid* (annexed formula), crystallises in slender, white needles, m. p. 322—323°, with slight browning at 320°.



2-*Phenyltriazolephthalonic acid*, $Ph\cdot N_3{:}C_6H_2(CO_2H)\cdot CO\cdot CO_2H$ [$N_3Ph : CO_2H : CO\cdot CO_2H = 12 : 4 : 3$], prepared by oxidising benzeneazo-β-naphthylamine by means of alkaline permanganate solution, crystallises in lustrous, white needles, m. p. 242°. T. H. P.

s-Trinitroarylazodiarylamines. A. BERETTA (*Gazzetta*, 1923, **53**, 870—876).—By the action of picryl chloride on aminoazo-derivatives in alcoholic solution in presence of sodium acetate, the author has prepared the *s*-trinitrophenyl derivatives of various *o*-, *m*-, and *p*-aminoazo-compounds of the benzene and naphthalene series.

3′-*Benzeneazo*-2 : 4 : 6-*trinitrodiphenylamine*,

$$(NO_2)_3C_6H_2\cdot NH\cdot C_6H_4\cdot N{:}NPh,$$

obtained from *m*-aminoazobenzene, crystallises in slender, yellow needles, m. p. 212°, and dissolves in concentrated sulphuric acid to a yellow solution. 4′-Benzeneazo-2 : 4 : 6-trinitrodiphenylamine (cf. Walther and Lehmann, A., 1904, i, 352) has m. p. 178°. 3′-*Methyl*-6′-p-*tolueneazo*-2 : 4 : 6-*trinitrodiphenylamine*,

$$C_6H_4Me\cdot N{:}N\cdot C_6H_3Me\cdot NH\cdot C_6H_2(NO_2)_3,$$

prepared from *p*-tolueneazo-*p*-toluidine, forms slender, slightly orange, red crystals, m. p. 201°, and gives a red solution in concentrated sulphuric acid. 2′-*Methyl*-4′-o-*tolueneazo*-2 : 4 : 6-*trinitrodiphenylamine* crystallises in red needles, m. p. 194°, and dissolves in concentrated sulphuric acid to a red solution. 3′-*Amino*-4′-*benzeneazo*-2 : 4 : 6-*trinitrodiphenylamine*, $C_{18}H_{13}O_6N_7$, prepared from 2 : 4-diaminoazobenzene (chrysoidine), forms minute, red crystals, m. p. 254° (decomp.), and gives a red solution in concentrated sulphuric acid. 3′-*Amino*-6′-*methyl*-4′-*benzeneazo*-

2 : 4 : 6-*trinitrodiphenylamine*, $C_{19}H_{15}O_6N_7$, prepared from 2 : 4-diaminoazomethylbenzene (methylchrysoidine), forms slender, lustrous prisms with metallic reflexion, m. p. 228° (decomp.), and dissolves in concentrated sulphuric acid to a red solution. 3′-*Acetylamino*-6′-*methyl*-4′-*benzeneazo*-2 : 4 : 6-*trinitrodiphenylamine* crystallises in slender, orange-yellow prisms, m. p. 215° (decomp.). 3′-*Amino*-6′-*methyl*-4′-p-*chlorobenzeneazo*-2 : 4 : 6-*trinitrodiphenylamine*, $C_{19}H_{14}O_6N_7Cl$, prepared from 4′-chloro-2 : 4-diamino-5-methylazobenzene, crystallises in slender, metallic brown prisms, m. p. 235° (decomp.), and forms a red solution in concentrated sulphuric acid. The corresponding 3′-*acetylamino*-compound separates in slender, orange crystals, m. p. 228° (decomp.). 3′-*Amino*-6′-*methyl*-4′-p-*bromobenzeneazo*-2 : 4 : 6-*trinitrodiphenylamine*,

$$C_{19}H_{14}O_6N_7Br,$$

crystallises in slender, lustrous, brown needles, m. p. 233° (decomp.), and dissolves in concentrated sulphuric acid to a red solution. The corresponding *acetylamino*-derivative forms slender, orange needles, m. p. 227° (decomp.).

α-*Benzeneazo*-β-*naphthyl*-2 : 4 : 6-*trinitrophenylamine*,

$$Ph{\cdot}N_2{\cdot}C_{10}H_6{\cdot}NH{\cdot}C_6H_2(NO_2)_3,$$

prepared from benzeneazo-β-naphthylamine, crystallises in slender, reddish-brown needles, m. p. 221° (decomp.), and dissolves in concentrated sulphuric acid to a blue solution. α_2-*Benzeneazo*-α_1-*naphthyl*-2 : 4 : 6-*trinitrophenylamine* forms slender, reddish-brown needles, m. p. 193° (decomp.), and yields a blue solution in concentrated sulphuric acid. T. H. P.

Studies in Dyes with Multiple Chromophores. R. N. SEN and B. SETT (*J. Amer. Chem. Soc.*, 1924, **46**, 111—119).—Three types of azo-triphenylmethane dyes have been studied containing, respectively, one, two, and three azo-groups in the *p*-position to the central carbon atom. It has been found that the introduction of one azo-group deepens the colour (compare T., 1912, **101**, 1113), of two azo-groups lightens the colour, and of three makes it still lighter. The effect of the multiplication of chromophores has also been studied by introducing simultaneously an azo-methine group and an azo-group into chrysoidine, rosaniline, safranine, and Congo-red, and in each case the colour becomes lighter. The direct-dyeing property of Congo-red also disappears. The introduction of the azo-group has been found to deepen the colour in the case of an indamine dye as well as in the case of fluorescein.

The preparation and properties of the following dyes, which appear to be new substances, are described: *phenetoleazosulphophenyltetramethyldiaminodiphenylcarbinol* (from phenetoleazobenzaldehydesulphonic acid and dimethylaniline) dyes wool green; *dimethylaminobenzeneazophenyltetramethyldiaminodiphenylcarbinol* (from benzeneazodimethylaniline and tetramethyldiaminobenzhydrol) dyes wool blue; *salicylylazophenyldisalicylylcarbinol* (from methylenedisalicylic acid and benzeneazosalicylic acid) dyes wool red; *phenyldi(dimethylaminobenzeneazophenyl)carbinol* (from benzaldehyde and benzeneazodimethylaniline) dyes wool violet; *phenetoleazosulphophenyldi(dimethylaminobenzeneazophenyl)carbinol* (from phenetoleazobenzaldehydesulphonic acid and benzeneazodimethylaniline) dyes wool yellow; *diphenetoleazosulphobenzylidenechrysoidine* (from chrysoidine hydrochloride and phenetoleazobenzaldehydesulphonic acid) dyes wool golden-yellow; *diphenetoleazosulphobenzylidene-rosaniline hydrochloride* (from rosaniline and phenetoleazobenzaldehydesulphonic acid) dyes wool bluish-red; *diphenetoleazosulphobenzylidene-safranine hydrochloride* (from safranine and phenetoleazobenzaldehydesulphonic acid) dyes wool red; *dimethylaminobenzeneazophenyldimethylquinoneimine hydrochloride* (from nitrosodimethylaniline hydrochloride and benzeneazodimethylaniline) dyes wool olive-green; *sulphobenzeneazofluorescein* (from diazotised sulphanilic acid and fluorescein) dyes wool orange.

F. A. M.

Amine Oxidation. VIII. Oxidation of Aliphatic Amines. S. Goldschmidt and V. Voeth (*Annalen*, 1924, **435**, 265—277).—Benzylamine is oxidised by potassium permanganate in aqueous or in acetone solution to give benzaldehyde, no intermediate compound being isolable even if oxidation be effected at −60°. Since, however, benzaldehyde, under similar conditions, is rapidly oxidised to benzoic acid, it cannot be the primary product in the oxidation of benzylamine, which probably proceeds thus: $\mathrm{PhCH_2{\cdot}NH_2} \longrightarrow \mathrm{PhCH_2{\cdot}N{:}} \longrightarrow \mathrm{PhCH{:}NH} \longrightarrow \mathrm{PhCH{:}O+NH_3}$.

Dibenzylamine is oxidised by permanganate in acetone solution to give *benzoyltribenzylhydrazine* (white needles, m. p. 181°), the constitution of which was established by synthesis (from tribenzoylhydrazine and benzoyl bromide); its formation is explained by the scheme: $\mathrm{2(PhCH_2)_2NH} \longrightarrow \mathrm{2(PhCH_2)_2N{:}} \longrightarrow \mathrm{(PhCH_2)_2N{\cdot}N(CH_2Ph)_2} \longrightarrow \mathrm{(PhCH_2)_2N{\cdot}NBz{\cdot}CH_2Ph}$. Confirmation of this explanation was obtained: tetrabenzylhydrazine on oxidation with permanganate gives benzoyltribenzylhydrazine, which, on reduction with zinc dust and acetic acid, yields benzylbenzamide (and traces of benzaldehyde and dibenzylamine), and on treatment with mineral acids gives (per mol.) benzaldehyde (1 mol.) and *hydroxytribenzylhydrazine hydrochloride*. The latter (m. p. 220—240° [indef.]) could not be obtained in a pure state and was found to contain dibenzylamine hydrochloride, whilst, on treating it with alkali, benzamide and tribenzylhydrazine were isolated.

The oxidation of di-*n*-propylamine by means of permanganate gives *αβ-dipropionyl-αβ-di-*n*-propylhydrazine*,

$$\mathrm{COEt{\cdot}NPr^{\alpha}{\cdot}NPr^{\alpha}{\cdot}COEt}.$$

This substance, evidently formed by the oxidation of the first-formed tetrapropylhydrazine, was only obtained in a slightly impure state as a yellow oil possessing an odour like that of menthol, and beginning to decompose at 40° (more readily in presence of alkali) with formation of propaldehyde. The dipropionyl derivative, on being distilled, affords a mixture of propaldehyde, n-*propylpropionamide*, $\mathrm{NHPr^{\alpha}{\cdot}COEt}$ (pale yellow oil, b. p. 64—65°/

0·4 mm.), and n-*propylidenepropionamide*, CHEt:N·COEt (viscous, greenish-yellow oil, b. p. 87°/0·4 mm.).

Aqueous permanganate with piperidine gave no isolable products, but in acetone solution oxidation proceeded much more rapidly than in the cases described already, to give N-*piperidyl*-N-2-*piperidone* as a yellowish-red oil, which, on distillation, was converted into a mixture of tetrahydropyridine and 2-piperidone (b. p. 64—65°/0·4 mm.). E. E. T.

Certain Nitroarylhydrazines. M. Giua (*Gazzetta*, 1923, **53**, 844—851).—The results obtained when various aromatic nitro-compounds are treated with semicarbazide show that the latter serves to replace by the residue $\cdot NH\cdot NH\cdot CO\cdot NH_2$, not only the nitro-group, but also labile halogen atoms. Thus, when heated on a water-bath in alcoholic solution containing sodium acetate, 1-chloro-2 : 4-dinitrobenzene and semicarbazide react in accordance with the equation: $C_6H_3Cl(NO_2)_2+2NH_2\cdot NH\cdot CO\cdot NH_2=C_6H_3(NO_2)_2\cdot NH\cdot NH\cdot CO\cdot NH_2+NH_2\cdot CO\cdot NH\cdot NH_2,HCl$. In the case of nitro-compounds containing a labile nitro-group, the formation of nitrous acid renders the reaction somewhat complicated, and, although the yields of nitrophenylsemicarbazides are good, various secondary products are also formed. With β- and γ-trinitrotoluenes the first phase of the reaction is probably expressed by the equation: $C_6H_2Me(NO_2)_3+2NH_2\cdot NH\cdot CO\cdot NH_2=C_6H_2Me(NO_2)_2\cdot NH\cdot NH\cdot CO\cdot NH_2+NH_2\cdot CO\cdot N_3+2H_2O$; the azide of carbamic acid has not been observed among the secondary products, but small proportions of cyanuric acid, which is one of the many transformation products of this azide, have been detected (cf. Curtius and Schmidt, A., 1923, i, 1080).

4 : 6-*Dinitro*-m-*tolylsemicarbazide*, obtained by the action of semicarbazide on γ-trinitrotoluene, forms crystals, m. p. 237—238° (decomp.). 2 : 4-*Dinitro*-m-*tolylsemicarbazide*, similarly obtained from β-trinitrotoluene, forms crystals, m. p. 185° (decomp.), and in alcoholic solution yields a reddish-brown coloration with alkalis. 5-*Chloro*-2 : 4-*dinitrophenylsemicarbazide*, prepared from 1-chloro-2 : 4 : 5-trinitrobenzene, forms yellow crystals, m. p. 217—218° (decomp.). 2 : 4-*Dinitrophenylsemicarbazide*, $C_7H_7O_5N_5$, prepared from 1-chloro-2 : 4-dinitrobenzene, forms pale yellow crystals, m. p. 205—207° (decomp.).

α-*Methyl*-α-*phenyl*-5-*chloro*-2 : 4-*dinitrophenylhydrazine*,

$$Cl(NO_2)_2C_6H_2\cdot NH\cdot NMePh,$$

obtained by the interaction of *as*-methylphenylhydrazine and 1-chloro-3 : 4 : 6-trinitrobenzene, crystallises in orange-yellow lamellæ, m. p. 120—121°, and dissolves in concentrated sulphuric acid to a reddish-brown solution.

Acetone 4 : 6-*dinitro*-m-*tolylhydrazone*, $C_{10}H_{12}O_4N_4$, crystallises in yellow needles, m. p. 144—145°, and in alcoholic solution gives a dark red coloration with an alkali. Other 4 : 6-dinitro-*m*-tolylhydrazones are those of: *acetophenone*, $C_{15}H_{14}O_4N_4$, crystallising in orange-yellow needles, m. p. 215—216°; *ethyl phenyl ketone*, $C_{16}H_{16}O_4N_4$, forming a red, crystalline powder, m. p. 183—184°;

benzaldehyde, $C_{14}H_{12}O_4N_4$, crystallising in reddish-yellow needles, m. p. 224—225°; *anisaldehyde*, separating in garnet-red prisms, m. p. 238—239° (decomp.); p-*tolualdehyde*, $C_{15}H_{14}O_4N_4$, forming lustrous, deep red needles, m. p. 237—238°; *cinnamaldehyde*, $C_{16}H_{14}O_4N_4$, forming bright red needles, m. p. 263—264° (decomp.).

T. H. P.

Additive Reactions of the Phosphorus Halides. VIII. Kinetic Evidence in Regard to the Mechanism of the Reaction. J. B. Conant and V. H. Wallingford (*J. Amer. Chem. Soc.*, 1924, **46**, 192—202; cf. A., 1923, i, 498).—The reaction between benzaldehyde and phosphorus trichloride proceeds to a definite equilibrium both in the absence of a solvent and in benzene solution. The composition of the equilibrium mixture accords with the law of mass action. An earlier explanation of the mechanism of the reaction between carbonyl compounds, phosphorus trichloride, and acetic acid or anhydride assumed that this addition reaction was an intermediate step; this explanation is now abandoned. The gradual addition of small amounts of water to a mixture of benzaldehyde and the trichloride causes an irreversible reaction to take place. The product appears to be an open-chain phosphorus compound which readily loses hydrogen chloride to form a phostonic acid derivative (cf. Conant and Macdonald, A., 1921, i, 69). The reaction between a trichloride, an aldehyde, and acetic acid must be either a direct interaction of three molecules or a reaction in which some open-chain additive product of an unstable nature is an intermediate; the authors favour the latter alternative. F. A. M.

Action of Halogen Derivatives of Phosphorus on some Phenolic Bases. M. Bourneuf (*Bull. Soc. chim.*, 1923, **33**, [iv], 1808—1823).—When dimethylaniline (2 mols.) is heated at 70° with phosphorus trichloride (1 mol.), *p*-dimethylaminophenyldichlorophosphine, $NMe_2\cdot C_6H_4\cdot PCl_2$, is primarily formed, since sodium carbonate converts the product into a mixture (with dimethylaniline) of *tetramethyldiaminodiphenylphosphine oxide*, $(NMe_2\cdot C_6H_4)_2PHO$, m. p. 169° (insoluble), and dimethylaminophenylphosphinic acid (soluble, and stable towards boiling water; cf. Michaelis and Schenk, A., 1888, 834). The above oxide, in presence of water and air, gives tetramethyldiaminodiphenylphosphinic acid (m. p. 249—250° on Maquenne block, or 199° [decomp.] in capillary tube), the latter being formed, together with *hexamethyltriaminotriphenylphosphine dihydroxide*, $(NMe_2\cdot C_6H_4)_3P(OH)_2$, (m. p. 321° on Maquenne block) in the original condensation.

Diethylaniline and phosphorus trichloride give non-crystalline products.

Dimethylaniline (4 mols.), when heated with 1 mol. of phosphorus oxychloride at 130°, the product then being treated with sodium hydroxide, gives a mixture of (1) tetramethyldiaminodiphenylphosphinic acid, affording dimethylaniline when heated with calcium carbonate or with mineral acids; *sodium* salt,

$$(NMe_2\cdot C_6H_4)_2P(ONa)\colon O,H_2O;$$

(2) tetramethyldiaminodiphenylmethane, and (3) *hexamethyltriaminotriphenylphosphine oxide*, m. p. 262°, and the corresponding hydroxide (cf. *supra*).

Diethylaniline is converted by phosphorus oxychloride into *tetraethyldiaminodiphenylphosphinic* acid (m. p. 195° [decomp.] or 253—254° on Maquenne block), which is decomposed on heating with calcium carbonate or with mineral acids to give diethylaniline; it forms a *dihydrochloride* (hygroscopic, m. p. 185° on Maquenne block), a *sodium* salt (crystallising with 6 or $7H_2O$), and a *barium* salt.

Orthophosphoric acid and aniline give only aniline pyrophosphate.

E. E. T.

Studies Concerning the Direct Preparation of Organo-beryllium Halides. H. GILMAN (*J. Amer. Chem. Soc.*, 1923, **45**, 2693—2695).—Metallic beryllium, even when freshly cleaned by treatment with very dilute pure nitric acid, does not react with methyl iodide, ethyl iodide, benzyl bromide, bromobenzene, chlorobenzene, or α-bromonaphthalene, using as solvents anhydrous ether, anisole, benzene, or β-ethoxynaphthalene, and as catalysts iodine, bromine, dimethylaniline, ethyl acetate, or freshly prepared Grignard reagent. Experiments in which freshly sublimed beryllium iodide was used, and one in which the reaction mixture was exposed to *X*-rays, were also unsuccessful. W. S. N.

Action of Polyhalogenated Derivatives of Methane and Ethane on Magnesyl [Magnesium Alkyl] Compounds. III. R. BINAGHI (*Gazzetta*, 1923, **53**, 879—887; cf. A., 1922, i, 313, 1002).—Towards magnesium ethyl bromide, tetrachloromethane behaves similarly to chloroform, giving only ethylene and methane. With magnesium phenyl bromide, however, it yields, not tetraphenylmethane, but hexaphenylethane, triphenylmethyl peroxide, and triphenylcarbinol. This reaction exhibits marked analogy to the formation of hexaphenylethane by the action of zinc on triphenylchloromethane (cf. Gomberg, A., 1901, i, 77, 638; 1913, i, 259), which is yielded by the first phase of the reaction $3MgPhBr+CCl_4=CPh_3Cl+3MgBrCl$. The latter compound then reacts with another molecule of magnesium phenyl bromide, giving hexaphenylethane and bromobenzene, which also occurs among the products of the reaction $2CPh_3Cl+MgPhBr=MgCl_2+PhBr+CPh_3\cdot CPh_3$. That the reaction proceeds thus is confirmed by the simultaneous formation of triphenylcarbinol, which, under the experimental conditions employed, could not arise except by the hydrolysis of the triphenylchloromethane either by the water added to precipitate the basic magnesium salt or by the current of steam used to remove the bromobenzene and diphenyl. Atmospheric oxidation of hexaphenylethane explains the formation of triphenylmethyl peroxide, which is not obtained when an atmosphere of hydrogen is employed.

In the reaction between magnesium ethyl bromide and tetrachloromethane, the first phase consists of the addition of four molecules of the magnesium alkyl compound to one molecule of the methane derivative, evolution of gases occurring only when the product of the reaction is either left for some time or heated: $CCl_4+4MgEtBr=4MgClBr+4C_2H_4+CH_4$.

Triphenylmethyl peroxide, $O{:}O(CPh_3)_2$, forms a lustrous, white, microcrystalline powder, m. p. 186°, and yields rather low values for the molecular weight in freezing naphthalene. By dissolution in cold, concentrated sulphuric acid and subsequent addition of the solution to ice, triphenylcarbinol is obtained. Its *hexanitro-derivative*, $O{:}O[C(C_6H_4{\cdot}NO_2)_3]_2$, has m. p. 208—210°. T. H. P.

Arsino-arylamino-alcohols. C. W. Rodewald and R. Adams (*J. Amer. Chem. Soc.*, 1923, **45**, 3102—3105).—Amino-arylarsinic acids on condensation with β-chloroethyl and γ-chloropropyl chloroformates yield ω-chloroalkyl-(arsino-aryl)carbamates. On treatment with two molecular equivalents of aqueous alkali, the β-chloroethyl compounds are converted into arsino-aryl oxazolidones and the γ-chloropropyl compounds into 3-arsino-aryl-tetrahydro-1 : 3 : 2-oxazones. Excess of alkali hydrolyses the oxazolidones to β-arsino-aryl amino-ethanols and the oxazones to γ-arsino-aryl-aminopropanols. β-*Chloroethyl* (p-*arsinophenyl*)*carbamate*,

$$C_6H_4(AsH_2O_3)NH{\cdot}CO_2{\cdot}CH_2{\cdot}CH_2Cl,$$

has m. p. above 250°, the corresponding (o-*arsinophenyl*)*carbamate* having m. p. 156—157°. β-*Chloroethyl* (2-*methyl*-5-*arsinophenyl*)*carbamate* has m. p. 193—195°. The γ-*chloropropyl* (p-*arsinophenyl*)*carbamate*, $C_6H_4(AsH_2O_3)NH{\cdot}CO_2{\cdot}[CH_2]_3{\cdot}Cl$, and the corresponding o-*arsinophenylcarbamate* melt at 245—246° and 130—132°, respectively. γ-*Chloropropyl* (2-*methyl*-5-*arsinophenyl*)*carbamate* has m. p. 160—162°. 3-p-*Arsinophenyl*-2-*oxazolidone*, $C_6H_4(AsH_2O_3){\cdot}N{\cdot}CO_2{\cdot}CH_2{\cdot}CH_2$, forms colourless plates, m. p. above 280°.

3-o-*Arsinophenyl*-2-*oxazolidone* crystallises in colourless plates, m. p. 212—213°. 3-p-*Arsinophenyl*-1 : 3 : 2-*oxazone*,

$$C_6H_4(AsH_2O_3){\cdot}N{\cdot}CO_2{\cdot}CH_2{\cdot}CH_2{\cdot}CH_2,$$

crystallises in white plates, m. p. 245—247°. β-(p-*Arsinophenyl*)-*aminoethanol*, $C_6H_4(AsH_2O_3)NH{\cdot}CH_2{\cdot}CH_2OH$, has m. p. 173—174°; the corresponding o-*arsinophenyl* derivative has m. p. 144—146°. β-(2-*Methyl*-5-*arsinophenyl*)*aminoethanol* has m. p. 144—146°. γ-(p-*Arsinophenyl*)*aminopropanol* has m. p. 167—168°; the similar o-*arsinophenyl* compound has m. p. 84—85°. γ-(2-*Methyl*-5-*arsinophenyl*)*aminopropanol* melts at 142—143°. p-*Arsinophenyl*-β-*hydroxyethyl nitrosoamine*, $C_6H_4(AsH_2O_3)N(NO){\cdot}CH_2{\cdot}CH_2OH$, is obtained from the corresponding aminoethanol and nitrous acid. It crystallises in bright yellow needles, m. p. 236°. p-*Arsinophenyl*-γ-*hydroxypropyl nitrosoamine*, $C_6H_4(AsH_2O_3)N(NO)CH_2{\cdot}CH_2{\cdot}CH_2OH$, is prepared similarly. It forms yellow crystals, m. p. 142—143°. The arsino-aryl-amino-alcohols are much less toxic than the corresponding arsanilic acids. F. G. P.

The Protein Matter of Bile. J. F. Logan (*J. Biol. Chem.*, 1923, **58**, 17—32).—Attempts have been made by various methods to isolate a pure protein from ox bile, and elementary analyses have been made of several of the preparations obtained. The results, however, indicate that, in each case, the product was probably a mixture of glucoprotein with a small amount of nucleoprotein. Direct acid hydrolysis did not liberate a reducing carbohydrate, but when this followed preliminary treatment with alkali the product had slight reducing properties. E. S.

Proteins of Wheat Bran. I. Isolation and Elementary Analyses of a Globulin, Albumin, and Prolamine. D. B. JONES and C. E. F. GERSDORFF (*J. Biol. Chem.*, 1923, **58**, 117—131).—Wheat bran, as free as possible from other portions of the wheat kernel, has been found to contain 17·25% of protein ($N \times 6{\cdot}25$). By extracting the bran successively with water, 4% sodium chloride, 70% alcohol, and 0·5% sodium hydroxide, 86·61% of the total protein has been removed and an albumin, a globulin, and an alcohol-soluble protein (prolamine) have been isolated from the first three extracts. Elementary analyses gave the following results: albumin, C=53·21, H=6·71, N=15·42, S=1·35%; globulin, C=53·43, H=7·40, N=17·76, S=0·91%; prolamine, C=54·25, H=6·75, N=15·35, S=1·35%. E. S.

Theory of Vegetable Tanning. II. Dehydration of the Gelatin Sol by Tannic Acid, Crystalline Tannins, and Simpler Phenols. H. G. B. DE JONG (*Rec. trav. chim.*, 1924, **43**, 35—67; cf. A., 1923, i, 821).—The stability of a gelatin sol is governed by two factors, electric charge and hydration. At the isoelectric point, p_H =4·7, the gelatin sol is uncharged, but retains its stability above the gelation temperature (about 40°) on account of its hydration. Increase of the hydrogen-ion concentration causes the particles to assume a positive charge, up to a maximum, beyond which the charge decreases. In the same way, decrease of the hydrogen-ion concentration imparts a negative charge to the particles up to a point, beyond which discharge takes place. Isoelectric or discharged sols can be coagulated by addition of dehydrating substances such as alcohol. Hydration changes in a sol can be followed by viscosity measurements, although the charge can also influence the viscosity (the quasi-viscous effect). This view of gelatin sols, it is claimed, expresses their behaviour better than the view which regards them as ion disperse systems.

It is shown by viscosimetric measurements that gelatin sols at 40° obey Poiseuille's law, and that the viscosity minimum is situated, at 40°, at the isoelectric point. The effect of tannic acid and phenols on gelatin sols was studied viscosimetrically at this temperature at different hydrogen-ion concentrations. At a small concentration of hydrochloric acid (0·003*N*), tannic acid has a marked dehydrating action, indicated by a lowering of the viscosity, but no precipitation occurs. At the isoelectric point tannic acid has both a dehydrating and a positive charging action on account of its own slight acidity. Consequently the viscosity minimum of a gelatin sol containing tannic acid lies at a small nominal concentration of alkali, which serves to restore the medium to the p_H of the isoelectric point. Further addition of alkali causes a powerful rehydration. The dehydration is relatively greatest at the isoelectric point, and, if pushed far enough, causes coagulation. The primary action of tannic acid on gelatin sols is therefore the same as on agar sols (*loc. cit.*). Phenol, pyrocatechol, resorcinol, quinol, pyrogallol, phloroglucinol, and ethyl gallate all have a similar dehydrating action on gelatin sols, the dehydrating action increasing rapidly with the number of phenolic groups. In the case of the two crystalline tannins, *d*-catechin and hamameli tannin, the dehydration is more powerful than with the simpler phenolic compounds. In the case of digalloylglucose, however, the positively charging influence of the tannin, tending to increase the viscosity, exceeds the dehydrating action, tending to lower the viscosity, at the isoelectric point, so that the viscosity is actually raised. However, a little sodium hydroxide in this case causes complete coagulation. Picric acid added to an isoelectric gelatin sol exerts at first a positively charging action, but with greater concentrations dehydration becomes very powerful, the positively charging action decreases, and finally precipitation occurs. Sodium picrate has no dehydrating action. E. H. R.

Gradual Decomposition of Proteins. Partial Hydrolysis of Keratin (Hog Bristles). E. ABDERHALDEN and E. KOMM (*Z. physiol. Chem.*, 1924, **132**, 1—11).—Hog bristles (400 g.) were heated with 1% hydrochloric acid (2 litres) in an autoclave at 120° for five hours, the product was neutralised with ammonia and then evaporated to dryness, mixed with sand and extracted with ethyl acetate. From the extract there were obtained *d*-alanylglycine anhydride, m. p. 250° (decomp.); prolyl-leucine anhydride, m. p. 158°, $[\alpha]_D^{20}$ −46·3° (in alcohol) (apparently partly racemised); l-*prolyl*-d-*valine anhydride*, m. p. 250—252°, and a *compound*, $C_{14}H_{23}O_3N_3$, m. p. 180—182°, which yields, on hydrolysis, proline, leucine, and alanine, and is formed from these by the loss of 3 mols. of water. From the product of the hydrolysis of hog bristles, using 70% sulphuric acid for seven days, the only pure compound isolated was l-*leucylserine*, $[\alpha]_D^{21}$ −44·3° (in water), and from the product of the hydrolysis by 70% sulphuric acid for fourteen days, a *valylvaline*, m. p. 255—260°, $[\alpha]_D^{20}$ +3·5° (in water), was obtained. In both cases, however, other scission products were shown to be present. W. O. K.

Biochemistry.

Iron Content of the Blood and Spleen in Infectious Equine Anæmia. L. H. WRIGHT (*J. Agric. Res.*, 1923, **26**, 239—242).—Analyses of the blood and spleens of a number of normal and anæmic animals are given. It would appear that the average total of the solids—iron, hæmoglobin, and erythrocytes—is considerably greater in the case of normal horses. Anæmia is indicated more by a lack of iron, and therefore of hæmoglobin, than by the number of erythrocytes. The increased iron content of the spleens of young horses is not considered to be entirely due to the larger amount of blood in the organ. A. G. P.

Relation between the Phosphate in Blood and Urine. V. B. Wigglesworth and C. E. Woodrow (*Proc. Roy. Soc.*, 1924, **B**, **95**, 558—570).—After the ingestion of acid or of alkaline sodium phosphate containing 1·5—2 g. of phosphorus, there is a 50—60% increase in the phosphate content of the blood, and simultaneously a large increase in the urinary phosphate. The urinary excretion of phosphorus is roughly proportional to the excess of phosphate above a certain value in the blood. Little change in the rate of excretion of phosphorus is caused by large variations in the amount of water excreted. The plasma and corpuscles normally contain equal amounts of inorganic phosphate, but when the phosphate in the whole blood is increased, that in the plasma exceeds that in the corpuscles. The organic fraction of the acid-soluble phosphorus does not increase after phosphate ingestion, or after ingestion of glucose with or without phosphate. W. O. K.

Some Experiments and Remarks on the Possible Transformation of *d*-Glucose in the Intestine and on the Nature of the Blood-sugar. S. Van Creveld (*Biochem. J.*, 1923, **17**, 860—871).—In agreement with Stiven and Reid (A., 1923, i, 1153), the observations of Hewitt and Pryde (A., 1920, i, 648) have not been confirmed. Using the aqueous humour of the eye and the blood-serum ultra-filtrate, it is shown that, although the former fluid when freshly collected decolorises potassium permanganate, neither fluid shows any mutarotation, and the copper-reducing value and the rotatory power are in close correspondence. In general, from the author's observations, no experimental support is forthcoming for the view that "reactive" sugars are intermediate metabolites, but the view that such may possibly occur is not abandoned. J. P.

The Absence of Effect of Insulin on the Heat Production in Isolated Frog's Muscle. R. Azuma and W. Hartree (*Biochem. J.*, 1923, **17**, 875—877).—Insulin has no effect either on the initial or on the recovery heat production of the isolated sartorius muscle of the frog. Injection of insulin into the intact frog produces convulsions which are relieved by glucose administration. J. P.

Studies on Carbohydrate Metabolism. II. On the Preparation of an Anti-diabetic Hormone from Yeast. I. H. B. Hutchinson, W. Smith, and L. B. Winter (*Biochem. J.*, 1923, **17**, 683—692).—A glucokinetic substance with physiological reactions closely resembling those of insulin may be extracted from yeast by methods similar to those used for preparing the pancreatic hormone. The lowering of blood-sugar may be followed by convulsions which are relieved by glucose injections. Various yeasts give very variable results, and only in the case of active yeasts does the activity increase on culturing. J. P.

Studies on Carbohydrate Metabolism. III. On the Formation of an Anti-diabetic Hormone by the Action of a Bacillus. (Preliminary Communication.) H. B. Hutchinson, W. Smith, and L. B. Winter (*Biochem. J.*, 1923, **17**, 764—767).—Injection into rabbits of an extract of the medium in which cultures of a coliform bacillus from yeast had been grown, produced hypoglycæmia and convulsions which were relieved by glucose administration. J. P.

The Transformation of Creatine into Creatinine. A. Hahn and L. Schäfer (*Z. Biol.*, 1924, **80**, 195—210).—A series of experiments on rabbits and on human beings shows that neither oral administration nor subcutaneous injection of creatine causes an increased output of creatinine. Of the creatine administered, a variable proportion appears in the urine; the fate of the remainder is unknown. The transformation of creatine into creatinine is a function of the muscles, and depends on the physico-chemical conditions there obtaining (probably the most important being the hydrogen-ion concentration), and not on the action of an enzyme. C. R. H.

The Fate of Indolepropionic Acid in the Animal Organism. F. W. Ward (*Biochem. J.*, 1923, **17**, 907—915).—Indolepropionic acid was prepared by the anaërobic action of a mixed culture of *Bacillus coli*, *B. chauvei*, *B. sporogenes*, and *B. œdemaciens* on tryptophan (cf. Hopkins and Cole, A., 1903, i, 590). Intravenous injection of indolepropionic acid gives rise to a keto or enol form of a 2-hydroxyindole compound. Indole-ethyl alcohol is oxidised to indole-acetic acid, whilst indolecarboxylic acid is excreted unchanged as a conjugated compound, and is therefore not an intermediate step in the oxidation of indolepropionic acid. J. P.

Experiments with Two Methods for the Study of Vitamin-*B*. H. C. Sherman and Harriet Edgeworth (*J. Amer. Chem. Soc.*, 1923, **45**, 2712—2718).—The importance of vitamin-*B* as a factor in food values makes it desirable that quantitative methods of known precision be applied in all studies of the vitamin contents of different foods. The gravimetric yeast-growth method was employed, using the Williams medium, and dried skimmed milk was used as the source of the vitamin. The growth was continued for thirty hours at 18°, being then arrested by the addition of formaldehyde. Consistent results were obtained, the probable errors being of the order of 1% of the observed numerical values. The method is open to the objection that the increased growth measured may be due to the introduction of other substances favourable to yeast-growth. The rat-growth method was also used and gave quantitative results, the probable error being in this case 2—4% of the numerical values. F. G. P.

A Critical Investigation and an Application of the Rat-growth Method for the Study of Vitamin-*B*. H. C. Sherman and Adelaide Spohn (*J. Amer. Chem. Soc.*, 1923, **45**, 2719—2728).—The rats used were fed on basal diets designed to be devoid of vitamin-*B*, and to contain all the other essential food factors in as nearly as possible the optimum proportions. Variations in the basal diets were made, fixed amounts of milk being used as sources of vitamin. It appears to be established from the results obtained that all increases of growth resulting from the addition of the milk to the basal diets used may be attributed to the vitamin-*B* thus furnished. There is no evidence of any measurable diminution of vitamin-*B* in milk powder heated dry at 100°, with free access of air. Probably about one-fourth of the vitamin is destroyed when the milk is heated in the fluid state for six hours at 100°.

F. G. P.

A Quantitative Study of the Destruction of Vitamin-*B* by Heat. H. C. Sherman and M. R. Grose (*J. Amer. Chem. Soc.*, 1923, **45**, 2728—2738).—The juice of canned tomatoes was used as a source of vitamin-*B* in this investigation, and the effect of heating at 10° intervals over the range of 100—130° has been examined, using the rat-growth method (see preceding abstract) as a measure of the vitamin content. At 100°, in a slightly acid medium, there is an appreciable destruction of the vitamin, and the results obtained at different temperatures show that the temperature coefficient of the destructive process is distinctly lower than that of most chemical reactions, resembling, in this respect, that of vitamin-*C*. It is therefore improbable that the vitamin is an unstable protein, and inappropriate to group it with enzymes, since typical enzymes have shown rates of destruction by heat with high temperature coefficients up to the point at which the enzymic activity was entirely destroyed. F. G. P.

A Preliminary Note on the Destruction of Vitamin-*B* by Age. G. M. Findlay (*Biochem. J.*, 1923, **17**, 887—890).—Indian lentils and peas which had been kept for thirty-eight years and had lost their power of germination showed, when fed to rats, a slight loss of vitamin-*B* in comparison with recent samples of these seeds.

J. P.

The Alleged Specific Colour Reaction for the Antiscorbutic Factor. H. D. Kay and S. S. Zilva (*Biochem. J.*, 1923, **17**, 872—874).—The blue colour given by the Bezssonoff reagent (*Bull. Soc. Chim. biol.*, 1922, **4**, 83) with certain preparations of the antiscorbutic vitamin is not specific. The constituent responsible for the coloration is, like the vitamin, destroyed by oxidation.

J. P.

Contributions towards the Study of the Lipoids of the Human Brain. F. Popescu (*Bul. Soc. Chim. România*, 1923, **5**, 83—92).—The author describes in detail the isolation of the lipoids present in the human brain, and extends the general methods for the determination of lipoids in blood (Grimbert and Laudet, A., 1913, ii, 164) to this case. A new method for the desiccation of the brain by means of freezing is described. After complete freezing, the brain is maintained at 40° for half an hour and the soft paste so obtained dried rapidly and completely in a vacuum. Extraction of the dried powder with acetone removes cholesterol, fats, and the phosphatides. The cholesterol separates from the hot extract on cooling, and is removed by filtration. The whole of the cholesterol present in the brain is found to exist in the free state and not combined with oleic acid. From the residue, a new *lipoid*, of the phosphatide group, having the composition $C = 67\cdot02\%$, $H=9\cdot93\%$, $N=2\cdot50\%$, $P=0\cdot534\%$, was isolated. This is soluble in alcohol and acetone, insoluble in cold ether, is precipitated by cadmium chloride, and gives no reaction with nitric or sulphuric acid. The solution of the lipoids remaining is precipitated with lead acetate, and yields mainly lecithin and a small quantity of kephalin. The residue from the acetone extraction is extracted with light petroleum; addition of alcohol to the concentrated extract precipitates kephalin (7—8%), and the alcoholic solution contains lecithin (5·5%).

The residue insoluble in acetone and light petroleum is finally extracted with alcohol, and this extract yields the substances contained in the grey matter (protagon), sphingomyelin (containing phosphorus) and phrenosin, and kerasin (phosphorus-free).

The determination of the lipoids present in a tubercular brain shows that the quantity of cholesterol is larger, and the quantity of other lipoids smaller, than in the normal brain.

For details of the separation and determination, the original paper must be consulted. J. W. B.

Gradual Decomposition of Proteins. Partial Hydrolysis of Keratin (Hog Bristles). E. Abderhalden and E. Komm.—(See p. 343.)

Auto-histo-radiographic Method for the Detection in Organs of Injected Polonium. A. Lacassagne and (Mme.) J. S. Lattès (*Compt. rend.*, 1924, **178**, 488—490).—The authors have made use of the α-ray emission of polonium, and its relatively long period of disintegration of 140 days, to obtain auto-radiograms of organs capable of retaining it. A rabbit was injected with polonium salts and killed after six days. Thin sections of the principal organs were made and placed on the sensitive surface of a photographic plate. After several days' exposure, records were obtained of the distribution of polonium. Retention by the various organs was very unequal, being greatest in the organs of elimination.

A. B. H.

Researches on Cellular Disintegration. A. Nodon (*Compt. rend.*, 1924, **178**, 486—487).—It is shown that living organisms, vegetable and animal, exhibit radioactivity, which appears to be a function of the degree of vitality of the organism. The radioactivity varied with the nature of the organism, and was increased by sunlight. The conclusion is drawn that both the disintegration

of radium and that of the living cell have their origin in exterior ultra-radiations, also that the atoms constituting the living material must acquire special properties, which allow them to disintegrate in a manner similar to those of the radioactive elements.
A. B. H.

[Cellular Disintegration.] D. Berthelot (*Compt. rend.*, 1924, **178**, 487).—The author observed in 1909 and 1910 phenomena similar to those observed by Nodon (preceding abstract). These he found to be due solely to changes of humidity. A. B. H.

The Extraction of the Concretion Gland and Nephridium of *Cyclostoma elegans*. P. Quast (*Z. Biol.*, 1924, **80**, 211—222).—A qualitative analysis of the concretion gland indicated the presence of silicates among the inorganic constituents and of uric acid, xanthine, hypoxanthine, and adenine among the organic ones. In the nephridium were found creatinine and allantoin.
C. R. H.

On the Participation of a Peroxidase in the Appearance of the Pigment in *Drosophila melanogaster*, Loew. De Luna (*Compt. rend.*, 1924, **178**, 525—527).—It is shown that a peroxydase takes part in the pigmentation of *Drosophila*. The peroxydase has the same distribution as the pigment. The appearance of the pigment is a function of temperature if the quantities of oxygen and peroxydase are constant; anæsthetics retard pigmentation.
A. B. H.

The Extractives of *Eledone moschata*. D. Ackermann, F. Holtz, and F. Kutscher (*Z. Biol.*, 1924, **80**, 155—162).—From this organism the authors have isolated betaine, taurine, lactic acid, and in addition two new bases which are designated *eledonine* ($C_{14}H_{30}O_3N_2$) and *homoeledonine* ($C_{15}H_{32}O_3N_2$). They both give chloroaurates melting indefinitely at 225—235°. The formula previously given to crangonine (A., 1908, ii, 53) is revised and now becomes $C_{13}H_{28}O_3N_2$, so that these three bases would appear to be members of an homologous series. C. R. H.

The Extractives of *Holothuria tubulosa*. D. Ackermann, F. Holtz, and H. Reinwein (*Z. Biol.*, 1924, **80**, 163—170).—In addition to betaine, adenine, and lactic acid, there was obtained from the lysine fraction a *chloroaurate* (m. p. 134°) of a base isomeric with homoeledonine (see preceding abstract). This substance on hydrolysis with hydrochloric acid gives betaine, and has therefore been named betainogen. C. R. H.

The Extractives of *Mytilus edulis*. D. Ackermann (*Z. Biol.*, 1924, **80**, 193—194).—Adenine was obtained in the purine fraction, and in the filtrate from the phosphotungstic acid precipitation was found the cyclose mytilitol (A., 1921, i, 764). C. R. H.

Proteins of Milk-serum. Their Separation by the Acetone Method. M. Piettre (*Compt. rend.*, 1924, **178**, 333—335).—The milk is coagulated rapidly by shaking at 35° and adding rennet, drop by drop, until casein begins to separate in a flocculent condition, after which the serum is filtered off by suction. It is rendered feebly acid with hydrochloric acid, extracted with ether, and the residual liquid precipitated by means of acetone and filtered. The precipitate is digested with water, and $N/10$-hydrochloric acid added in sufficient quantity to precipitate the lactoglobulin, which is then collected (using a centrifuge) and found to have $[\alpha]_D$ $-31° 12'$ in aqueous sodium hydroxide solution. The clear filtrate on precipitating, *e.g.*, with alcohol, affords the pure lactalbumin, with $[\alpha]_D$ $-41{\cdot}23°$. Milk contains, on the average, 2·3 g. of globulin and 3·2 g. of albumin per l. E. E. T.

Observations on certain Reducing and Oxidising Reactions of Milk. P. Haas and T. G. Hill (*Biochem. J.*, 1923, **17**, 671—682).—There is present in milk an oxygen acceptor capable of reducing sodium nitrate to nitrite, to which the name "*atite*" is provisionally given, and also an oxygen donator bringing about the reverse conversion of nitrite to nitrate (cf. Bach, A., 1911, i, 759) which has been called "*itate.*" Atite is precipitated with the milk proteins, and, although thermolabile, is not regarded as being an enzyme. Unlike atite, which is most active in the absence of oxygen, itate is active only in its presence, but in its thermolability and precipitation reactions it resembles the former. Both substances require an accelerator, aldehydes, notably acetaldehyde, being most active. Acetaldehyde in the presence of oxygen destroys both atite and itate. The diminution in the peroxydase reaction of milk is parallel to the rate of destruction of itate, and the possible identity of the last with peroxydase is considered. Atite is distinct from Schardinger's reductase. J. P.

The Protein Matter of Bile. J. F. Logan.—(See p. 341.)

The Occurrence of Amines in Urine. P. N. van Eck (*Pharm. Weekblad*, 1924, **61**, 65—73).—In testing samples of urine for blood, it was occasionally observed that a beautiful orange-red colour developed on addition of benzidine and glacial acetic acid, and before the addition of hydrogen peroxide. Out of 61 samples of urine, 25 gave positive results. Investigation failed to show that this was due to any specific malady or remedy. Negative tests were obtained with some twenty substances likely to be present in urine, and with the extracts obtained by shaking urine with the ordinary organic solvents. It was found, however, that the distillates from many urines gave the reaction, and contained alkylamines; the lower alkylamines were then examined, and all gave the reaction. By testing urine from healthy persons it was found that a positive result always followed a meal of pickled herrings, in which amines were identified, and that amines could be identified in the distillates from these urines, by the *iso*nitrile and nitroprusside reactions.

A collection of observations on the occurrence of alkylamines in animal and vegetable matter from various sources is given.

S. I. L.

Camphorylcarbamates and their Physiological Action. H. E. Fierz-David and W. Müller.—(See i, 301.)

The Physiological Effect of Gossypol. P. Menaul (*J. Agric. Res.*, 1923, **26**, 233—237).—The toxic effect of gossypol on rabbits was slow to appear if the substance was given with the food, but when it was injected directly into the blood-stream, the effects were apparent almost at once. It was found that gossypol prevents the normal oxygen-interchange in the blood, and also has a hæmolytic effect. Death is caused by a reduced oxygen-carrying power of the blood, which considerably increases the work of the respiratory and circulatory organs. This explained the condition of dead animals, viz., a passive hyperæmia and œdema of the lungs and some hydrothorax, which is directly due to the effect of gossypol and does not result from bacterial action. A. G. P.

Hypnotic Properties of Hydrobenzoin and of its Alkylated Homologues (Symmetrical Diarylglycols). Relations between Physiological Activity and Molecular Weight. M. Tiffeneau and C. Torres (*Compt. rend.*, 1924, **178**, 237—239).—The hypnotic effect, on the stickleback, of hydrobenzoin, and of its methyl, ethyl, *iso*propyl, butyl, *iso*butyl, and *iso*amyl derivatives has been measured (cf. A., 1923, i, 676). It is concluded that the hypnotic effect and molecular weight increase together. When, in a series (*e.g.*, in the present one, at the *iso*amyl member) the solubility limit is reached, the hypnotic effect then decreases as the molecular weight increases, unless biliary substances are added to promote absorption by the organism. E. E. T.

Constitution and Mode of Action of Biochemical Catalysts or Enzymes. Effects of Electrolysis on Enzymes of Pancreatic Juice and on the Amylase of Germinated Barley. F. Maignon (*Compt. rend.*, 1924, **178**, 420—423).—Preparations of the enzymes from the pancreatic juice of the cow, and of amylase from barley have been found to contain calcium, iron, and chlorine. On being electrolysed in aqueous solution, coagulation sets in near the anode, but not near the cathode. Finally, coagulation ceases, and the enzyme is found to be inactive, owing to removal of the inorganic constituents by electrolysis. The author concludes that the chlorine-ion is attached to the proteinic micellæ, the kations (Fe and Ca) being free in the liquid medium. In the case of hydrion, the latter is adsorbed on the external surface of the micellæ, this explaining (on ordinary adsorption theories) the great catalytic activity of that hydrion. E. E. T.

The Azine and Azonium Compounds of the Proteolytic Enzymes. I. H. R. Marston (*Biochem. J.*, 1923, **17**, 851—859).—Dyes of the azine group (eurhodines, safranines, indulines), but not their leuco-bases, quantitatively precipitate the proteolytic enzymes pepsin, trypsin, erepsin, and papain from their solutions. The enzyme is regarded as attaching itself to the azine nitrogen atom or atoms. Pepsin may be recovered in solution from the pepsin-azine precipitate by treatment with 0·5% hydrochloric acid and removal of the dye by extraction with amyl alcohol. It is suggested that the proteolytic enzymes may become attached to proteins, preliminary to hydrolysing them, through the nitrogen atoms of diketopiperazine groupings, and the results are interpreted in favour of the view that such groupings are present in the protein molecule. J. P.

Further Studies on the Enzymic Degradation of Polypeptides Composed of Amino-acids not yet found among the Degradation Products of the Proteins. E. ABDERHALDEN and A. MOSCHINI (*Fermentforschung*, 1923, 7, 176—178).—Yeast maceration juice degrades *d*-*n*-valyl-*l*-tyrosine but not *l*-*n*-valyl-*l*-tyrosine. In the former case, the formation of tyrosine and *d*-α-amino-*n*-valeric acid was demonstrated. The dipeptides were synthesised by combining *l*-tyrosine or its ester with *d*- or *l*-α-bromo-*n*-valeryl chloride. S. S. Z.

The Action of Enzyme Solutions on 3 : 5-Di-iodo-*l*-tyrosine and Glycyl-3 : 5-di-iodo-*l*-tyrosine. E. ABDERHALDEN and W. STIX (*Fermentforschung*, 1923, 7, 179—182).—Yeast maceration juice effects a cleavage in glycyl-3 : 5-di-iodo-*l*-tyrosine. Extract of pancreas and of the mucous membrane of the stomach do the same, but more slowly. Thyroid extract and thyroid press-juice have no action on the compound. S. S. Z.

The Action of the Enzymes of the Gastro-intestinal Tract on Diketopiperazine. E. ABDERHALDEN and K. GOTO (*Fermentforschung*, 1923, 7, 169—175).—It is concluded that neither trypsin nor pepsin has an appreciable hydrolytic action on *d*-alanylglycine anhydride, and that the hydrolysis which is effected by alkaline or acid solutions of these enzymes is due to that alkalinity or acidity. The anhydride was obtained by hydrolysing silk resides. S. S. Z.

Urease. II. The Mechanism of the Zymolysis of Urea. W. R. FEARON (*Biochem. J.*, 1923, 17, 800—812).—Using the method described by the author (A., 1923, i, 497), it is shown that cyanic acid and ammonia, but not carbamic acid, are intermediate products of the zymolysis of urea (cf. Mack and Villars, A., 1923, i, 405). Soja urease, which carries a negative electric charge, adsorbs urea from alcoholic solution and ammonia from aqueous solution. It is concluded that urease adsorbs its substrate, and that the adsorbed urea is then decomposed into ammonia and cyanic acid. The former is readsorbed as such by the enzyme and the latter is hydrolysed by the solvent water. The enzyme is again liberated by combination of the adsorbed ammonia with ammonium hydrogen carbonate and is free to adsorb more urea. The cyclic process continues until arrested by accumulation of ammonium carbonate or by exhaustion of the substrate. J. P.

Studies on Enzyme Action. The Relationship between the Chemical Structure of certain Compounds and their Effect upon the Activity of Urease. E. W. ROCKWOOD and W. J. HUSA (*J. Amer. Chem. Soc.*, 1923, 45, 2678—2689).—The effect of various compounds on the activity of urease obtained from jack-bean meal has been studied, and the following results have been obtained.

Certain compounds exert a promoter effect on the catalytic activity of the urease, others have an inhibitory action. These effects are independent of changes in hydrogen-ion concentration. The promoter effect is related to the presence of both amino and carboxyl groups. Compounds containing only one of these groups were not promoters. The promoter action seems to be a function of the distance between the groups, all the α-amino-acids used being marked promoters, β-amino-acids having a slight effect, and γ-amino-acids none. With the aminobenzoic acids, the order of decreasing effect is ortho, meta, para. A second amino or carboxyl group in an α-amino-acid increases the promoter action. α-Amino-acids of the heterocyclic nitrogen compounds have a slightly greater effect than simple α-amino-acids. Ammonium chloride, guanidine sulphate, creatine, and creatinine have no promoter effect. Enzymes appear to be of a protein nature or to occur associated with protein, and when the protein is removed from the enzyme solution, the activity is lost. The experiments which show the promoter action of α-amino-acids and peptones indicate that the protein part of enzyme preparations is an important factor in the action of the enzyme. The results obtained also tend to disprove the hypothesis that the promoter effect is due chiefly to prevention of decomposition of the enzyme. F. G. P.

Experiments Demonstrating the Existence of Specific Cytolysins for the Various Organs of the Animal Organism. A. ZERKOWITZ (*Fermentforschung*, 1923, **7**, 223—228).—It is claimed that some of the experiments carried out with the blood sera of normal and castrated rabbits, and the testicles and other organs of these animals, confirm the author's hypothesis of the existence of specific cytolysins. S. S. Z.

Carbohydrate and Fat Metabolism in Yeast. I. S. MACLEAN and D. HOFFERT (*Biochem. J.*, 1923, **17**, 720—741).—Yeast incubated in oxygenated water shows a diminished carbohydrate content and an increase in fat. Propyl, butyl, and *iso*amyl alcohols inhibit this conversion, whilst the sodium salts of formic, propionic, and butyric acids, glycol, glycerol, and acetone, in 0·1*M*-solution, behave like water. Incubation in 0·5% solutions of ethyl alcohol, or of the sodium salts of acetic, lactic, and pyruvic acids gives the same results as 0·5% solutions of dextrose; in the first two cases increase of the total carbohydrate of the yeast-cell is observed. In the presence of dextrose, lævulose, and sucrose the yeast-cell stores both carbohydrate and fat. Maltose is exceptional in producing a greater carbohydrate and lesser fat storage than the other sugars investigated. It is suggested that maltose is assimilated as such by the yeast-cell. Continuous oxygenation during incubation greatly increases the amount of fat produced, but has little or no effect on the carbohydrate. In oxygenated solutions, added phosphate reduces the amount of carbohydrate stored and increases the fat formation. Phosphate is taken up by the cell in proportion to the sugar concentration of the solution; more phosphate is taken up from oxygenated than from non-oxygenated solutions. It is suggested that the formation of hexose phosphate is the first stage in the conversion of carbohydrate into fat. J. P.

Irregularities of the Lactic Fermentation in Presence of certain Antiseptics. A. Lumière (*Compt. rend.*, 1924, **178**, 258—260).—It is shown that the supposed irregularity observed by Richet (*ibid.*, 1923, **177**, 1262) in connexion with the antiseptic action of mercuric chloride is due to the use, by this author, of inocula from non-uniform bacterial suspensions. If the latter are well shaken, in order to break up large aggregates, perfectly uniform results are obtained with antiseptics. E. E. T.

Production of β-Hydroxybutyric Acid by Microbial Processes. M. Lemoigne (*Compt. rend.*, 1924, **178**, 253—256; cf. A., 1923, i, 881).—The alcoholic extract of fresh cultures of *Bacillus M.* gives, on evaporation and distillation of the residue, α-crotonic acid. β-Hydroxybutyric acid is therefore a normal physiological product of the bacillus, and is formed from intracellular reserve material. E. E. T.

Variations in Hydrogen-ion Concentration under the Influence of the Assimilation of Nitrates by *Aspergillus repens*, De Bary. Bach (*Compt. rend.*, 1924, **178**, 520—522).—When *Aspergillus repens*, De Bary, is allowed to grow in a suitable medium containing nitrates and for which p_H has an initial value between 3·6 and 8·4, the hydrogen-ion concentration after ten days approximates to the value $p_H = 6$. The addition of potassium phosphate reduces the rate of the change, but does not alter its sense. A. B. H.

The Accumulation and Formation of Urea in Mushrooms. N. N. Ivanov (*Biochem. Z.*, 1923, **143**, 62—74).—The urea content and nitrogen distribution in mushrooms, artificially cultivated in manure, has been estimated at various stages of growth. The dried fungi may contain up to 13% of urea. The amount of urea increases during the ripening process until spore formation begins, autolysis of the proteins and chitin leading to an increase in the amino compounds, which are then converted to urea. By treatment with chloroform, the formation of urea may be inhibited. The high urea content is ascribed to the artificial culture in the nitrogen-rich medium. A close analogy is drawn between the formation of urea and asparagine (cf. also A., 1923, i, 428, 520). J. P.

The Migration of Inulin in the Grafts of Composites. H. Colin and R. Franquet (*Compt. rend.*, 1924, **178**, 518—520).—It is shown that when a branch of a plant containing inulin is grafted on a subject which does not normally contain this substance, the latter migrates into the subject, but undergoes hydrolysis to lævulose. It is sometimes possible, however, to detect the inulin in the immediate vicinity of the graft. The optical rotations of the sugars above and below the graft are frequently in opposite direction. A. B. H.

The Acidity of Maize and its Relation to Vegetative Vigour. A. M. Hurd (*J. Agric. Res.*, 1923, **25**, 457—468).—Measurements of the hydrogen-ion concentration and titratable acidity of the expressed juice of maize plants, showed these two factors to vary inversely as the vigour of the plant. Alterations in sap density did not account for variations in acidity, with the exception of a few cases where particularly high values were obtained. The concentration of titratable acid in the leaf-juice was always greater than in the stalk, whatever the state of vigour of the plant. In vigorous plants, the p_H values of the leaf juices were greater than those of the stalk juices. This relationship was reversed in the case of weakly, stunted plants. The density of the juice of the leaves was greater than that of the stalks, whether the plant was vigorous or otherwise. Variations in the acidity of plants of the same strain but in a different environment were considerably greater than those of different varieties under similar conditions of growth and vigour. A. G. P.

On the Significance of the Ash Content of certain Marine Algæ. P. Haas and B. Russell-Wells (*Biochem. J.*, 1923, **17**, 696—706).—From a comparison of the sulphate content of the hydrolysed aqueous extracts of certain marine algæ (*Rhodophyceæ* and *Phæophyceæ*) with the sulphate content observed after incineration, it is found that the former is greater than the latter and frequently in the ratio 2 : 1. This is ascribed to the presence of a complex calcium organic sulphate of the type $R{<}\substack{O\cdot SO_2\cdot O\\ O\cdot SO_2\cdot O}{>}Ca$, in which the calcium, but not the sulphate, is freely ionised. These colloidal complexes have a measurable conductivity and osmotic properties to which considerable importance is attached (cf. Harwood, T., 1923, **123**, 2254). J. P.

On the Determinable Iodine of *Laminaria flexicaulis*. P. Freundler (*Compt. rend.*, 1924, **178**, 515—517).—The iodine content of perfectly fresh *Laminaria flexicaulis* has been determined by three methods. The author concludes that the alga contains, in addition to its normal iodide content, a fairly constant quantity of a substance of unknown composition which is transformed into iodide on the death of the organism. A. B. H.

Quantitative Diurnal Variation of Starch in Green Plant Leaves. P. P. Stanescu (*Compt. rend.*, 1924, **178**, 117—119).—The starch-content of green leaves has been determined hourly or half-hourly, successive strips being cut from the same leaf at these intervals, and extracted with boiling water and alcohol. At the end of the day, the leaf is reassembled, and developed by immersion in iodine–iodide solution. The variation of starch-content throughout the day is then clearly seen. With most leaves (particularly from March to July) a single daily starch maximum is observed (*Robinia pseudacacia*, etc.). In August and September, two maxima are often observed. Several maxima are rarely found (*Rhus typhina* showing five). With *Chelidonium majus* and *Atriplex patula*, maxima and minima succeed each other rhythmically, whilst with *Urtica dioica* starch suddenly appears and as suddenly disappears again. E. E. T.

Galuteolin, a New Glucoside from *Galega officinalis*. G. Barger and F. D. White (*Biochem. J.*, 1923, **17**, 836—838).—From the seeds of *Galega officinalis* a glucoside, $C_{21}H_{20}O_{11},3H_2O$, to which the name *galuteolin* is given, has been isolated. It contains no methoxyl groups. On hydrolysis, it yields dextrose and an insoluble yellow colouring matter decomposing at 290—300°, of the composition $C_{15}H_{10}O_6$, identified as luteolin, which, when boiled with acetic anhydride containing a trace of sulphuric acid or pyridine, forms a tetra-acetyl compound, $C_{15}H_6O_6(C_2H_3O)_4$, long, colourless needles, m. p. 221—223°. Luteolin occurs as such in the seeds of *Galega officinalis*. The temperatures at which hydroxyflavones such as luteolin sublime in a high vacuum are characteristic. J. P.

Localisation of the Cyanogenetic Glucosides in *Prunus occidentalis* and *P. myrtifolia*. E. Mameli-Calvino (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 423—430).—By means of Treub's Prussian blue reaction the author has established the localisation of a cyanogenetic glucoside in the bark and leaves of *Prunus occidentalis* and *P. myrtifolia*. Peche's mercurous nitrate method is unsuitable for this purpose, since the reagent may be reduced by the action of cellular constituents which yield no hydrocyanic acid. Microchemical investigation fails to reveal the presence of alkaloids in the bark or leaves of these two species. T. H. P.

A Labile Form of Protein and its Relation to Living Protoplasm. II. O. Loew (*Biochem. Z.*, 1923, **143**, 156—160).—The occurrence is described, in various vegetable cells, of rounded, highly refractive protein droplets resembling the "caffeine proteosomes" previously discovered by the author (A., 1915, i, 1079). These are coagulated by the vapour of ether and chloroform, and combine with bases to form insoluble stable complexes. They also combine readily with water and are made insoluble by neutral salt solutions and by hydrocyanic acid. The reactivity of these droplets is discussed in relation to protoplasmic activity. J. P.

Proteins of Wheat Bran. I. Isolation and Elementary Analyses of a Globulin, Albumin, and Prolamine. D. B. Jones and C. E. F. Gersdorff.—(See this vol., i, 342.)

Detection and Distribution of Phytosterols in Latex. G. Klein and K. Pirschle (*Biochem. Z.*, 1923, **143**, 457—472).—An improvement is effected in the method available for the extraction of phytosterols from dried plant residues, by shaking the extract dissolved in light petroleum with 50% aqueous sodium hydroxide, whereby the impurities, which render recrystallisation difficult, are hydrolysed and may be subsequently washed out with aqueous sodium carbonate and distilled water. Crystallisation of the phytosterols then proceeds readily. Euphorbone has been obtained in this way, not only from the *Euphorbiaceæ*, but also from many other latex-forming plants, and its nature as a phytosterol has been established by the digitonin test (cf. Windaus, A., 1910, ii, 462).

The presence of 0·1 to 2·0% of phytosterol in latex is regarded as characteristic. A *bromo*- (m. p. 83°) and a *nitro*-derivative of euphorbone are described; a benzoyl derivative was not obtained (cf. Emmerling, A., 1908, i, 438). The physiological significance of phytosterols is discussed. J. P.

A Crystalline Metabolic Product from *Sparassis ramosa*. R. Falck (*Ber.*, 1923, **56**, [*B*], 2555—2556).—Remarkable growth of crystals is observed in pure cultures of *Sparassis ramosa* both in the substrate and on the surface. On the latter they are formed as long needles, in the former as small, rounded crystalline aggregates. The substance possesses the power of protecting the cultures from impurities in a remarkable manner. It can be isolated almost quantitatively by distillation of the substrate with steam. Its constitution has been elucidated by Wedekind and Fleischer (this vol., i, 174), by whom it has been designated "sparassol." H. W.

The Effect of Physiologically Acid and Alkaline Nitrogenous Fertilisers. F. Münter (*Z. Pflanz. Düng.*, 1923, **A**, **2**, 497—516).—The results of pot trials of the effect of various fertilisers on the yield of wheat and linseed are reported. They confirm the conclusions of earlier experiments. Physiologically acid nitrogenous fertilisers such as ammonium sulphate increase the availability of phosphorus in sandy soils so long as the soil reaction remains alkaline. Where a soil contains very small quantities of calcium carbonate, ammonium sulphate may depress the yield. The production of "alkali" in the soil as a result of heavy dressings of sodium nitrate depresses the availability of phosphorus and crop yield. Flax is more sensitive to alkalinity than is wheat. G. W. R.

Physiological Function of Iodine in the Sugar-beet. J. Stoklasa (*Compt. rend.*, 1924, **178**, 120—122).—Iodine (present as potassium iodide), although inimical to many plants, is absorbed by the leaves and roots of the sugar-beet, the weight of the whole plant and the percentage sucrose content increasing as a result. The moderate use (about 2 lb. per acre) of potassium iodide as a practical fertiliser in sugar-beet growing is therefore to be recommended, this applying even in the second year. A too free use (*e.g.*, 4 lb. per acre) of iodide, however, diminishes the growth and sucrose content, some arabinose appearing in the roots. E. E. T.

Lysimetric Studies. Soil and Subsoil in Calcium–Magnesium Interchange. W. H. MacIntire, W. M. Shaw, and J. B. Young (*Soil Sci.*, 1923, **16**, 321—341; cf. A., 1923, i, 1168).—Further data are given in connexion with lysimetric studies on soils treated with different compounds of calcium and magnesium. It is shown that the general effect of calcium dressings is to depress the outgo of magnesium from the soil and to increase the outgo from the subsoil. Magnesium dressings have a similar effect on the outgo of calcium from soil and subsoil. G. W. R.

Organic Chemistry.

Physical Properties of the Paraffin Hydrocarbons. R. E. Wilson and W. H. Bahlke (*Ind. Eng. Chem.*, 1924, **16**, 115—122).—Curves are presented between the following physical properties: vapour pressure and temperature, heat of vaporisation and vapour pressure, liquid density and temperature, and specific heat and temperature for the paraffin hydrocarbons from butane to tetracosane. These are compiled from published data and corrected and extended as follows: the vapour-pressure curve by Hildebrand's generalisation that the slope of the curve for any liquid is a constant if the vapour concentration is constant, with application of a correction based on Young's data for the lower members of the series; the heat of vaporisation on Hildebrand's similar rule that the molal entropy of vaporisation for all normal liquids is the same at equal vapour concentrations; the liquid density curve by the theorem of corresponding states. The critical data are calculated from Young's results and from the vapour-pressure curve. Only scanty specific heat data are available. [Cf. *B.*, 1924, 243.] C. I.

Characteristics of the Hydrocarbons in [American] Mid-continent Kerosene. C. R. Wagner (*Ind. Eng. Chem.*, 1924, **16**, 135—136).—The distillate from Oklahoma crude petroleum contains paraffins only in the most volatile fractions. When treated with half its volume of liquid sulphur dioxide at − 10°, a fraction soluble in the latter is separated of similar boiling point but higher specific gravity, the proportion of this fraction to the whole rising with the boiling point. In the case of a kerosene, b. p. 198—244°, the SO_2-soluble fraction amounted to 5·4%. This fraction was subjected to repeated fractional distillation under reduced pressure, yielding four main fractions, the freezing points, indices of refraction, elementary analyses, and molecular weights of which were determined. The suggested formulæ are $C_{12}H_{18}$, $C_{14}H_{20}$, $C_{13}H_{18}$, and $C_{14}H_{18}$; it appears probable that these compounds are partly hydrogenated substituted naphthalenes. Their characteristic property, which is common to all SO_2-soluble fractions of this petroleum, is that they are readily nitrated even by dilute nitric acid. The SO_2-insoluble oil was similarly fractionated and examined. This fraction is unaffected by sulphuric acid ($d = 1·68$) and consists essentially of members of the *cyclo*hexane series. C. I.

Velocity of Oxidation of Paraffin Wax. I—IV. F. Francis [with W. F. Millard, C. H. Rutt, C. M. Watkins, R. W. Wallington, and C. P. Garner] (*J. Chem. Soc.*, 1924, **125**, 381—393).—Paraffin wax, obtained from shale oil and fusing at 55—56°, is oxidised exothermally by a stream of air or oxygen at 100—135°. Commencement of reaction is preceded by a latent period, after which the oxygen content rises to 11—16% in 70—1800 hours. The latent period may be reduced by heating the wax, previous to oxidation, in a sealed vacuum (a treatment which does not alter the physical constants of the material, but slightly increases its solubility in chloroform and acetone), by the use of catalysts, and by previous treatment with sulphuric acid at 100°, which causes a loss in weight of about 5% of the material. Wax which, after being heated in a vacuum, was recrystallised from acetone had the same latent period as the untreated material. The latent period may therefore be ascribed to (*a*) the formation of a positive catalyst, (*b*) the destruction of a negative catalyst present in the original wax, or (*c*) isomeric change brought about by the action of heat, particularly the formation of unsaturated substances (cf. T., 1922, **121**, 498, 1534). Commencement of the oxidation is marked by the formation of carbon dioxide, and formic acid is always produced in the later stages of the reaction. The oxidation in presence of catalysts appears to take place in stages.

Wax treated at 100° with a stream of oxygen required 1060 hours to attain an oxygen content of 7%; with air at 100° the latent period was too long to determine, but at 120° an oxygen content of 7% was reached after 285 hours. Untreated wax in the presence of 5% of turpentine reached an oxygen content of 7% in 800 hours with air and in 320 hours with oxygen at 100°, in 285 hours with air at 120°, and in 46 hours with oxygen at 135°.

The temperature coefficient of the oxidation with oxygen is 1·6, whilst that of the latent period is 2·9. These values suggest that the rate of oxidation is governed by a physical process, but that the latent period is accompanied by a chemical change. Wax from lignite, having m. p. 46—47°, and containing 0·7% of oxygen, commenced to oxidise with oxygen at 135° after 10 hours, and contained 7% of oxygen after 24 hours. F. G. W.

Action of Iodine on Hydrocarbons. F. J. Nellensteyn (*Chem. Weekblad*, 1924, **21**, 102—106).—Iodine acts on all hydrocarbons, sometimes in the cold, but generally at high temperatures, forming hydrogen iodide, with separation of carbon and formation of colloidal carbon solutions. Treatment of paraffin oil at 160° gave a coal-like product, some 70% of the iodine added being driven off, mostly as hydrogen iodide, partly as free iodine. Reaction occurred at the ordinary temperature with a distillate from a Borneo asphaltic oil, *d* 0·886, b. p. 192—300°; at 160°, the iodine was converted nearly quantitatively into hydrogen iodide, carbon being formed both as a precipitate and in the colloidal condition. The results are interpreted as indicating reaction of the iodine with dissociation products of the hydrocarbons, containing only one carbon atom, *e.g.* $CH_3\cdot$, $CH_2:$, and $CH\vdots$. A highly unsaturated "cracked" gas-oil distillate, *d* 0·866, b. p. 58—150°, reacted with iodine very strongly at the ordinary temperature; the carbon which separated contained 30—37% of adsorbed iodine, not removable by thiosulphate or sodium hydroxide, but partly removed by alcohol. A high adsorbing power is to be expected, since the carbon is formed at low temperatures. The action of iodine is therefore analogous to that of oxygen, in that hydrogen is removed from dissociation products containing only one atom of carbon, with separation of the latter in the colloidal condition, thus forming asphalt. S. I. L.

Acceleration of the Reaction between Ethylene and Sulphuric Acid. W. GLUUD and G. SCHNEIDER (*Ber.*, 1924, **57**, [*B*], 254—255).—The absorption of ethylene by sulphuric acid is catalytically accelerated by the presence of lead sulphate, calcium sulphate, ferric sulphate, anhydrous copper sulphate, or, particularly, ferric ammonium alum. The most suitable catalyst, however, is silver sulphate added to the extent of 0·5—1% of the weight of sulphuric acid; in contrast to the other catalysts, this material retains its activity over long periods, so that higher concentrations of ethyl hydrogen sulphate can be attained. It is readily recovered by electrolysis. H. W.

Contact Condensation of Acetylene. N. ZELINSKY (*Ber.*, 1924, **57**, [*B*], 264—276).—The pyrogenic condensation of acetylene in the presence of activated birch or lime charcoal has been studied; the adsorbent properties of the material give, in effect, the action of very greatly increased pressure without involving the dangers incurred in working with compressed acetylene. The method has the advantage that the temperature can be raised without danger to 600—650°, at which the process proceeds most advantageously, and that, in consequence of the presence of charcoal, the condensation occurs quietly and without explosion of the acetylene, which need not therefore be diluted with an indifferent gas. The deposition of carbonised matter on the contact material takes place to only a very minor extent, and the formation of solid hydrocarbons (cuprene) is not observed. Further hydrogenation of the aromatic hydrocarbons which are produced is scarcely observable. The main product of the change is benzene.

The most favourable conditions for the condensation of acetylene are secured when the gas is passed at the rate of 20 litres per hour through a hard glass tube, about 1 metre long and 1·5—2·4 cm. internal diameter, heated at 650°. The escaping gases consist mainly of acetylene containing some ethylene; the yield of tar exceeds 70% of that theoretically possible.

The tar is reddish-brown in colour and aromatic in odour. Colour and transparency depend considerably on the temperature and freshness of the contact agent. Its density varies according to the temperature of the experiment from 0·911 (600°) to 0·995 (660°), but never exceeds 1. It is separated by distillation into the following fractions: light oil, b. p. below 170°, 49·0% (45% below 150°); middle oil, b. p. 170—230°, 11·7%; heavy oil, b. p. 230—270°, 9·5%; anthracene oil, 21·2%; pitch, 6·8% (loss 1·8%). The preliminary fraction contains small amounts of diacetylene, CH:C·C:CH. The light oil consists mainly of benzene (35% of the tar) accompanied by small amounts of toluene and *p*-xylene (cf. A., 1923, i, 1169). The presence of styrene in the fraction, b. p. 140—150°, and of indene in the fraction, b. p. 150—180°, is established. The middle oil solidifies at the atmospheric temperature to a yellow, crystalline mass, impregnated with liquid; it contains chiefly naphthalene. The green heavy oil contains large quantities of crystals of fluorene. The red anthracene oil deposits the hydrocarbon freely at the atmospheric temperature.

Reduction of the portion of the light oil boiling below 150° in the presence of nickel gives a mixture of cyclic hydrocarbons in which *cyclo*hexane predominates; it has b. p. 70—110°, d_4^{20} 0·7805, n^{24} 1·4238.

Acetylene is rapidly converted at 650° in the presence of active platinised asbestos into a pale yellow, transparent, aromatic tar, the yield being 45—50%; a portion of the acetylene, however, suffers decomposition in such a manner that the catalyst becomes coated with soot which ultimately inhibits the reaction; the tar is characterised by its very low content (5%) in pitch. Palladised asbestos is unsuitable for the condensation of acetylene. In the presence of pure, ignited asbestos, condensation of acetylene takes place at 650° with the production of a viscous, black, aromatic tar, d^{19} 1·000; the yield is about 40%. The action proceeds quietly without explosion, but cannot be continued over long periods on account of the deposition of soot. H. W.

Derivatives of Δ^{α}-Butylene. M. DE MONTMOLLIN and P. MATILE (*Helv. Chim. Acta*, 1924, 7, 106—111).—By the action of cold aqueous hypochlorous acid on Δ^{α}-butylene, *butylene-α-chlorohydrin*, $CH_2Me{\cdot}CH(OH){\cdot}CH_2Cl$, is obtained as a colourless liquid, b. p. 141°. When oxidised with chromic acid, it gives chloromethyl ethyl ketone, a liquid with a pungent odour, b. p. 135—137°; this is also formed as a by-product with the butylenechlorohydrin, together with αβ-dichlorobutane and some higher chlorinated products, including (?)*αβγ-trichloro-*n*-butane*, b. p. 165—168°/725 mm. *Butylene α-bromohydrin*, prepared from α-butylene and hypobromous acid, is a colourless liquid, b. p. 56—58°/11 mm. By oxidation it gives bromomethyl ethyl ketone, b. p. 145°/725 mm. This ketone is also formed as a by-product with the bromohydrin, together with some αβ-dibromobutane and a *bromobutylene bromohydrin*, b. p. 79—80°. The above chloromethyl ethyl ketone gives with phenylhydrazine a *compound*, yellow crystals, m. p. 210—215° (decomp.), whilst bromomethyl ethyl ketone gives a *compound*, greenish-yellow crystals, m. p. 200—205° (decomp.). Both appear to contain two phenylhydrazine residues, and should be the same phenylhydrazido-phenylhydrazone; the difference cannot yet be explained.

α-Butylene diacetate is obtained by heating αβ-dibromobutane with fused potassium acetate and glacial acetic acid; it is a colourless liquid with an agreeable odour, b. p. 196—199°. When this liquid is saturated with gaseous hydrogen bromide, *α-bromo*-sec.-*butyl acetate*, $CH_2Me{\cdot}CH(OAc){\cdot}CH_2Br$, a pale yellow liquid, b. p. 76°/15 mm., is formed. *α-Butylene oxide*, $CH_2Me{\cdot}CH{<}\overset{CH_2}{\underset{O}{|}}$, is formed by the action of potassium hydroxide solution on the chloro- or bromo-hydrin; it is a colourless liquid, b. p. 58·5—59·0°. It is converted by 25% ammonia solution into *α-amino-*sec.*-butyl alcohol*, b. p. 168—170°.

E. H. R.

Alkaline Reduction of the Carbon Tetrahalides and of Potassium *aci*-Nitroform. R. O. GRIFFITH and L. HUNTER (*J. Chem. Soc.*, 1924, **125**, 463—464).—The carbon tetrahalides are effectively reduced by phenylhydrazine, arsenious oxide, or sulphites in alkaline solution. The action of acetone, hydrazine, antimonious oxide, and stannites is less certain. In the reduction of trichlorobromomethane to chloroform by means of aqueous sodium arsenite, dichlorobromomethane was not formed. Bromoform is reduced to methylene bromide by alkaline reagents, with the production of much formate, and chloroform is hydrolysed to formate without the production of methylene chloride. The action of alkaline reducing agents on potassium *aci*nitroform does not produce potassium dinitromethane, the salt being completely decomposed with the formation of ammonia. Hydrazine or phenylhydrazine reacts with evolution of nitrogen, a result which may explain the abnormally large production of nitrogen in the reaction between these compounds and tetranitromethane (T., 1923, **123**, 2305; and 1920, **117**, 880).

F. G. W.

Preparation and Reactions of the Dihalogenodinitromethanes. R. A. GOTTS and L. HUNTER (*J. Chem. Soc.*, 1924, **125**, 442—450).—The action of potassium hydroxide, iodide, cyanide, and nitrite, and of sodium thiosulphate, on the dihalogenodinitromethanes was investigated to test the hypothesis of Macbeth (T., 1922, **121**, 1118), that the activity of halogen atoms in similarly constituted molecules is the result of an induced positive polarity. In general, the stability of the compounds investigated conforms to the order $Cl > Br > I$, although in the case of the mixed dihalogenodinitromethanes exclusive removal of the more positive atom does not take place.

Potassium hydroxide reacts with dichloro- and dibromo-dinitromethanes according to the equation, $CCl_2(NO_2)_2 + 2KOH = CKCl(NO_2)_2 + KClO + H_2O$. In the case of chlorobromodinitromethane, the product is a mixture of the potassium salts of chloro- and bromo-dinitromethane. Chloroiododinitromethane behaves similarly to the chlorobromo-compound, losing more iodine than chlorine.

Potassium iodide reacts with the dihalogenodinitromethanes according to the equation, $CX_2(NO_2)_2 + 2KI = CKX(NO_2)_2 + KX + I_2$, both halogens being removed in part, but chlorobromodinitromethane gives also a small proportion of the iodo-salt.

Potassium cyanide behaves more energetically than the iodide, and both halogen atoms can be removed according to the equations, $CX_2(NO_2)_2 + KCN = CKX(NO_2)_2 + CNX$ and $2CKX(NO_2)_2 + 2KCN + H_2O = 2CKH(NO_2)_2 + KX + CNX + KCNO$; potassium chlorodinitromethane, however, remains unaffected on prolonged treatment with potassium cyanide.

Potassium nitrite acts as a reducing agent only in the case of chloroiododinitromethane, according to the equation, $CClI(NO_2)_2+2KNO_2=CKCl(NO_2)_2+KNO_3+NO+I$. The action of potassium nitrite in presence of carbonate on dibromodinitromethane is represented by the equations, $CBr_2(NO_2)_2+KNO_2+K_2CO_3=CK(NO_2)_3+KBr+KBrO+CO_2$, and $CBr_2(NO_2)_2+KNO_2+K_2CO_3=CKBr(NO_2)_2+KBr+KNO_3+CO_2$. Chlorobromodinitromethane yields the nitroform salt in much smaller proportion, and none is obtained from the dichloro-compound.

Sodium thiosulphate reduces potassium bromo- and iodo-dinitromethanes to potassium dinitromethane; the chloro salt is reduced much more slowly.

The action of acids on potassium bromodinitromethane is represented by the equation, $2CKBr(NO_2)_2+H_2SO_4=CBr_2(NO_2)_2+K_2SO_4+N+NO+CO_2+H_2O$. Potassium chlorodinitromethane behaves analogously. For the purposes of preparation, the direct action of halogens gives better yields than that of acids. Copper, lead, and ferrous salts have a similar action to that of mineral acids, but the silver monohalogenodinitromethanes can be obtained as stable, crystalline substances.

Dichloronitromethane is best prepared by the action of strong nitric acid on 2 : 4-dichloroacetanilide, and purified by conversion into the potassium salt, from which it is regenerated by the action of aqueous chlorine; it is a colourless oil, d_4^{25} 1·6616, not solidifying above −10°. Dibromodinitromethane, similarly purified, is a colourless, pungent oil, d_4^{25} 2·3946, m. p. 7·4°. *Potassium chlorodinitromethane*, light yellow prisms exploding at 83—85°, decomposes on keeping. *Silver chlorodinitromethane*, long, yellow needles, explodes at 80—81°. Chlorobromodinitromethane is best prepared in presence of sodium acetate, and forms a colourless, pungent liquid, d_4^{25} 2·0472. *Potassium iododinitromethane*, obtained by the action of iodine on potassium dinitromethane in aqueous solution, forms orange-yellow plates, exploding at 154°. It does not darken on exposure when pure. The *silver* salt forms insoluble, pale yellow, glistening leaflets, exploding at 109—110°. F. G. W.

Aliphatic Nitro-alcohols. II. R. WILKENDORF and M. TRÉNEL (*Ber.*, 1924, 57, [*B*], 306—309).—An extension of previous work (A., 1923, i, 288).

β-Chloro-β-nitroethyl alcohol condenses with acetaldehyde in aqueous solution, in the presence of a little potassium carbonate, to form *β-chloro-β-nitrobutane-αγ-diol*, $OH·CH_2·CCl(NO_2)·CH(OH)·CH_3$, long needles, m. p. 104°; with propaldehyde, it gives *β-chloro-β-nitropentane-αγ-diol*, colourless needles, m. p. 107° (decomp.). It does not appear to react with higher aldehydes.

The sodium derivative of β-chloro-β-nitroethyl alcohol is converted by methyl iodide in methyl-alcoholic solution into *β-chloro-β-nitropropyl alcohol*, m. p. 114°.

ment with a mixture of nitric acid (d 1·4) and concentrated sulphuric acid into β-*chloro*-β-*nitroethyl nitrate*, a colourless liquid, d^{18} 1·568, which, when cautiously heated, decomposes into nitric acid and α-*chloro*-α-*nitroethylene*, a liquid, b. p. 54—55°/14 mm., which violently attacks the eyes; the latter substance can also be prepared by the action of phosphoric oxide on β-chloro-β-nitroethyl alcohol; in the presence of sodium hydrogen carbonate, it passes readily into a *polymeride*, m. p. 126—130° (decomp.), according to the manner of heating. H. W.

Preparation of Ethyl Ether by Williamson's Method. W. B. S. Bishop (*J. Soc. Chem. Ind.*, 1924, **43**, 23—24T).—Pure ethyl ether is obtained readily by Williamson's method, using ethyl iodide and sodium ethoxide. The yield is 80% of the theoretical (calculated on the ethyl iodide used). The oxidised copper gauze test for halogens is capable of detecting as little as 0·00004 g. of iodine present as ethyl iodide in 1 c.c. of ether. W. P. S.

Catalytic Dehydration of Ethyl Alcohol and Ether by Alumina. R. N. Pease and C. C. Yung (*J. Amer. Chem. Soc.*, 1924, **46**, 390—403).—The dehydrations were carried out in an electrically heated glass bulb of 35 c.c. capacity containing the alumina. The alcohol was run in from a burette at a uniform rate, and, when equilibrium conditions had been obtained, a test was made. It is found that appreciable quantities of ether as well as ethylene are formed from alcohol and that at 275° and 300° the amount of alcohol decomposed attains a maximum corresponding with about 65% conversion, whereas at 350° the reaction proceeds to complete dehydration with the production of ethylene. The maximum yield of ether was 60% at 250°. Ether decomposes readily at temperatures above 275°. The results are explicable on the theory that the dehydration of alcohol to ether is a reversible equilibrium corresponding with about 65% conversion, and that decomposition of the alcohol occurs in steps. Whilst the direct dehydration to yield ethylene is a possible mechanism, it is not necessary to assume it in order to account for the results. Water vapour and ethylene diminish somewhat the efficiency of the catalyst towards dehydration of alcohol. Alumina which has been used in the dehydration of ether appears to be peculiarly activated with respect to alcohol, and the yield of ethylene is nearly doubled. A. B. S.

Autoxidation of Ethers. A. M. Clover (*J. Amer. Chem. Soc.*, 1924, **46**, 419—430).—The oxidising properties acquired by ethyl ether when exposed to the air (A., 1922, i, 619) have been observed with several other ethers. In three cases, the ether peroxides have been obtained, whereas in the other cases, owing to the high boiling point of the ether, the peroxides could not be isolated. Aldehydes, esters, acids, and hydrogen peroxide were also formed. The hydrolysis of the peroxides, which yields acids, hydrogen peroxide, and aldehydes, is considered to occur in accordance with the schemes: $OR{\cdot}CHR'{\cdot}O{\cdot}OH + H_2O \rightarrow R'CHO + ROH + H_2O_2$ or $OR{\cdot}CHR'{\cdot}O{\cdot}OH \rightarrow R'CO_2H + ROH$ or $R'CO_2R + H_2O$. The ethers experimented with were: propyl ether; *iso*propyl ether; *n*-butyl ether; *iso*amyl ether, b. p. 168—171°; methylenediethyl ether, b. p. 86—89°; benzylmethyl ether, benzylethyl ether, b. p. 183—185°; dibenzyl ether. In the case of propyl, *n*-butyl, and methylenediethyl ethers, the *peroxides* were isolated and analysed.

A. B. S.

Sulphochromic Oxidation and β-Oxidation. M. POLONOVSKI (*Compt. rend.*, 1924, **178**, 576—578).—A study of the oxidation of aliphatic acids by means of dilute sulphuric acid–dichromate solutions at 100°. Acetic acid is unaffected. Propionic acid is oxidised slowly and incompletely, through pyruvic and acetic acids (α-oxidation). Butyric acid is oxidised rapidly, through acetoacetic acid (β-oxidation; α-oxidation is shown not to occur from a consideration of the oxidation–time curves). Valeric acid undergoes β-oxidation, which in this case produces propionic acid, oxidation decelerating as a result.

E. E. T.

Electrolysis of Potassium Oleate. G. W. F. HOLROYD and J. E. W. RHODES (*J. Chem. Soc.*, 1924, **125**, 438—442).—The apparent transport number of the oleic-ion in $0{\cdot}2N$-potassium oleate solution was found to be 0·725, in agreement with that obtained by McBain and Bowden (T., 1923, **123**, 2417) under different experimental conditions. Oleic acid is the chief product at the anode; neither oxygen nor oxidation products in amount demanded by the equation, $2R{\cdot}CO_2 + H_2O = 2R{\cdot}CO_2H + O$, were found. The apparatus used was a modification of Ostwald's, arranged to allow collection of gases evolved.

F. G. W.

Bromine Derivatives of α-Elæostearic Acid. M. ISHIO (*J. Pharm. Soc. Japan*, 1923, No. 501, 789—796; cf. T., 1903, **83**, 1042; 1912, **101**, 2082; Nicolet, A., 1921, i, 390).—Dibromo-α-elæostearic acid (73 g.), colourless plates, m. p. 91°, is prepared by adding bromine to a solution of α-elæostearic acid (150 g.) in ether or light petroleum cooled below −15°; if chloroform is used as solvent, a tetrabromide (35 g.), m. p. 115°, is produced from the acid (100 g.) or from the dibromide. The dibromide is changed by alcoholic potassium hydroxide solution into a viscous oil free from the halogen, the reduction of which with hydrogen in the presence of platinum black yields stearic acid. When the tetrabromide is treated with alcoholic potassium hydroxide, a dibromide, $C_{18}H_{30}O_2Br_2$ or $C_{18}H_{32}O_2Br_2$, lustrous crystals, m. p. 40—40·5°, is produced.

K. K.

Perilla Oil. III. Bromides of the Linolenic Acids of Perilla Oil. K. H. BAUER (*Chem. Umschau*, 1924, **31**, 83—86; cf. A., 1923, i, 180).—Considerable quantities of linolenic acid hexabromides, prepared from perilla oil, were debrominated with zinc and alcohol and the linolenic acid obtained was brominated again. The precipitated bromides were separated. The soluble bromides were then debrominated and the separated fatty acids submitted to oxidation by Hazura's method. The solid oxidation products were mixed with sand and extracted in succession with boiling ether, light petroleum, and alcohol. From the alcoholic extract a small quantity of an acid, m. p. 143—147°, was obtained. The aqueous solution of the soluble oxidation products yielded a small quantity of a yellowish-brown oil and linusic acid, m. p. 203°. *iso*Linusic acid was not found. The hexabromides obtained from perilla oil were satisfactorily recrystallised from boiling xylene, whereby hexabromostearic acid, m. p. 179—181°, was isolated. All attempts to separate the product into components by fractional crystallisation of large quantities were without effect, so that the substance is presumably homogeneous. Owing to the uncertainty surrounding the oxidation of and formation of additive compounds from these highly unsaturated substances, it is not considered safe to assume that, because linusic acid is the only hydroxy acid obtained from the soluble brominated linolenic acids, the oxidation of β-linolenic acid yields this acid only. Attempts to prepare hexahydroxystearic acids from hexabromostearic acids by treating them with silver oxide were unsuccessful. The effect of allowing perilla oil to remain for a long time in the dark in contact with a small quantity of iodine (conditions favourable to the transformation of α- into β-elæostearic acid in the case of tung oil) was studied; steric rearrangement did not occur under the conditions chosen.

H. C. R.

Glycerides of Lard. II. Synthetical. C. Amberger and A. Wiesehahn [and, in part, J. Bauch] (*Z. Unters. Nahr. Genussm.*, 1923, **46**, 291—299).—α-Oleo-βγ-distearin [glyceryl α-oleate βγ-distearate], m. p. 42°, was synthesised by Fischer and Pfähler's method (A., 1920, i, 807) from α-mono-olein and stearyl chloride. α-Palmito-αβ-diolein, synthesised in a similar manner from α-monopalmitin and oleyl chloride, is a dark yellow oil which solidifies at 0°. Attempts to synthesise oleopalmitostearin were unsuccessful. A comparison of the properties of the mixed glycerides isolated from lard with those synthesised (cf. A., 1922, i, 804) and those obtained by their hydrogenation, leads to the conclusion that the following are present: β-palmito-αγ-distearin, β-stearo-αγ-dipalmitin, α-oleo-αβ-distearin, α-palmito-αβ-diolein, and probably β-oleo-α-palmito-γ-stearin.

H. C. R.

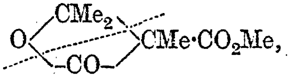
Crystalline Bromides of Linseed Oil. H. Toms (*Analyst*, 1924, **49**, 77—81).—A substance, m. p. 153° (corr.), is obtained by successive treatment of the crude bromide from linseed oil with ethyl acetate, alcohol, and ether. Its analysis agrees closely with the formula, $C_{57}H_{94}O_6Br_{16}$, from which it is concluded that it is a linolic–dilinolenic bromoglyceride. Its solubility in ethyl acetate at 15—20° is 0·15—0·20 g. per 100 c.c. The residue obtained from the ethyl acetate mother-liquor yields a small amount of material, m. p. 117° (corr.). The analysis of this substance corresponds approximately with the formula, $C_{57}H_{98}O_6Br_{12}$, and it may be trilinolic bromoglyceride or an oleic–linolic–linolenic bromoglyceride. Attempts were made to determine the bromide which was insoluble in ethyl acetate, and there were indications that the amount of the most unsaturated glyceride in linseed oil is a constant proportion of the total unsaturated substances present. H. C. R.

Uncommon Animal Fats. W. N. Rae (*Analyst*, 1924, **49**, 83—84).—The analytical characters of the fats of the following wild animals of Ceylon are given: leopard (*Felis pardus*), sambhur (*Cervus unicor*), spotted deer (*C. axis*), peafowl (*Pavo cristatus*), and wild boar (*Sus cristatus*). The values for leopard's fat agree closely with those given by Lewkowitsch for tiger's fat, and the values for the two members of the deer tribe agree with those of the chamois. European wild boar fat, however, differs considerably from that of the Ceylon wild boar. [Cf. *B.*, 1924, 264.] H. C. R.

β-Lactones of β-Hydroxybutyric Acid and its Alkyl Derivatives and the Influence of Constitution on the Decomposition of β-Lactones. H. Salkowski, jun. (*J. pr. Chem.*, 1923, **106**, 253—265).—When α-dialkylated β-hydroxybutyric acids are distilled they decompose into acetaldehyde and a dialkylacetic acid. A somewhat similar reaction to this is the thermal decomposition of methyl β-hydroxy-α-methyl*iso*propylmalonolactone, $O<\substack{CMe_2\\ CO}>CMe\cdot CO_2Me$, into acetone, dimethylketen, and carbon dioxide. To determine whether the decomposition of the β-hydroxybutyric acid may be preceded by the intermediary formation of a β-lactone which then decomposes into aldehyde and keten, the latter subsequently taking up the elements of water, β-lactones of β-hydroxybutyric acid, β-hydroxy-α-ethyl- and β-hydroxy-αα-dimethyl-butyric acids, were prepared and their thermal decomposition was studied.

The required hydroxybutyric acid derivatives were prepared by reduction of the corresponding derivatives of ethyl acetoacetate with sodium amalgam. β-*Hydroxy-α-ethylbutyric acid* is a viscous liquid, b. p. 123°/0·8 mm. β-*Hydroxy-αα-dimethylbutyric acid* forms a viscous liquid, b. p. 108—110°/0·02 mm., which slowly crystallises to bunches of needles, m. p. 34°. Part of the acid is converted into an *anhydride*, $OH\cdot CHMe\cdot CMe_2\cdot CO\cdot O\cdot CHMe\cdot CMe_2\cdot CO_2H$, b. p. 200—203°/15 mm., a very viscous liquid. The β-hydroxy-acids were converted into β-bromo-acids. For this purpose β-hydroxybutyric acid and β-hydroxy-α-ethylbutyric acid had first to be converted by distillation into the corresponding crotonic acid and the product treated with liquid hydrogen bromide. β-*Bromo-α-ethylbutyric acid* is a yellow, viscous liquid, b. p. 140—143°/15—16 mm.; β-*bromo-αα-dimethylbutyric acid* forms brown needles, m. p. 42°, b. p. 115°/0·2 mm. The lactones were obtained by treating the acids with sodium carbonate solution and extracting with ether. α-Ethyl-β-butyrolactone has b. p. 75°/13 mm. (cf. Johansson and Hagman, A., 1922, i, 426) and *αα-dimethyl-β-butyrolactone* has b. p. 63—65°/14 mm. The thermal decomposition of the lactones in each case gave carbon dioxide and an olefine, β-butyrolactone giving propylene, α-ethyl-β-butyrolactone giving amylene, and αα-dimethyl-β-butyrolactone giving α-methylbutylene. The decomposition is therefore different from that of the αα-dialkyl-β-hydroxybutyric acids.

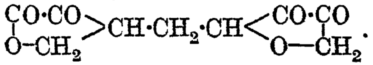
The type of β-lactone decomposition occurring in the case of methyl β-hydroxy-α-methyl*iso*propylmalonolactone,



$$O<\begin{array}{l}CMe_2\\ CO\end{array}>CMe\cdot CO_2Me,$$

the so-called ketone-splitting, can probably only take place when the β-carbon atom is tertiary. E. H. R.

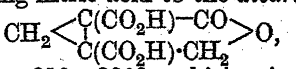
Condensation between Pyruvic Acid and Formaldehyde. Y. Asahina and S. Terada (*J. Pharm. Soc. Japan*, 1923, No. 502, 855—878).—The action of pyruvic acid on formaldehyde gives a compound, $C_9H_8O_6$, colourless plates, m. p. 239—240° (decomp.), which is shown to be methylenebis-α-ketobutyrolactone,



$$\begin{array}{l}CO\cdot CO\\ O{-}CH_2\end{array}>CH\cdot CH_2\cdot CH<\begin{array}{l}CO\cdot CO\\ O{-}CH_2\end{array}.$$

It gives the following derivatives: *ammonium* salt, $C_9H_7O_6\cdot NH_4$, white, silky crystals; *potassium* and *sodium* salts; unstable *silver* salt, $C_9H_6O_6Ag_2$, white scales; *ethyl* ester, m. p. 124—125°; monoacetyl derivative, scales, m. p. 135°; *dibenzoyl* compound, m. p. 122°; *phenylhydrazine* salt, $C_9H_8O_6,(Ph\cdot NH\cdot NH_2)_2$, white crystals, m. p. 195—196°; *phenylhydrazone*, $C_9H_8O_4(N\cdot NH\cdot Ph)_2$, m. p. 225—227° (decomp.); *semicarbazide* compounds, m. p. 196—197° (decomp.), and m. p. 182—183° (decomp.), respectively; *chloro-compounds*, m. p. 151—152°, and m. p. 183—184°. When heated at 145° with concentrated sulphuric acid, it yields an anhydride, $C_9H_6O_5$, white crystals, which do not melt below 300°.

Methylenebis-α-ketobutyrolactone is oxidised by silver oxide to the *substance*,  $CH_2<\begin{array}{l}C(CH_2OH)\cdot CO\\ C(CO_2H){-}CH_2\end{array}>O$, colourless, hexagonal crystals, m. p. 185—185·5°. It is not coloured by ferric chloride, but gives the pine-shaving reaction and contains one carboxy group, one lactone ring, and one hydroxy group. It yields a *methyl* ester, silky crystals, m. p. 105—105·5°, a *monoacetyl* derivative, m. p. 130°, and *monobenzoyl* compound, m. p. 130—131°. When heated with hydriodic acid and red phosphorus, it gives two iodine *compounds*, $C_7H_{10}O_4I_2$, m. p. 168—169° and 143—144°, respectively. When reduced with sodium amalgam, the former iodine compound gives *cis*-αγ-dimethylglutaric acid and the other the *trans*-isomeride. It is oxidised by fuming nitric acid to the *dicarboxylic acid*,



$$CH_2<\begin{array}{l}C(CO_2H){-}CO\\ C(CO_2H)\cdot CH_2\end{array}>O,$$

white crystals, m. p. 219—220°, which gives the pine-shaving reaction and contains two carboxyl groups and one lactone ring. Its *dimethyl* ester, prisms, melts at 77·5—78·5°. By heating with hydriodic acid and red phosphorus, it gives an iodine *compound*,

$C_6H_8O_4I_2$, m. p. 167—168°, the reduction of which with sodium amalgam produces αα-dimethylsuccinic acid. The similarity between the relation of β-tetronic acid to methylenebis-β-tetronic acid and that of α-tetronic acid to methylenebis-α-ketobutyrolactone was observed spectrographically. K. K.

Influence of Strong Acids on the Solubility of Oxalic Acid. W. Herz and E. Neukirch (*Z. anorg. Chem.*, 1923, **131**, 303—309).—The solubility of oxalic acid is depressed by the addition of a strong acid (hydrochloric, sulphuric, nitric) up to a certain concentration of the latter, after which it is increased. No action could be detected between oxalic and sulphuric acids up to a 3·5-molar concentration of the latter. Nitric acid exerts an oxidising effect, apparently due to impurities, and the figures obtained with this acid are not accurate. The results obtained are compared with those calculated on the solubility-product principle, the agreement being fair except in the case of nitric acid. [Cf. *B.*, 1924, 277.] S. K. T.

Photochemical Sensitisation of the Maleic Ester Transformation by means of Bromine. J. Eggert [with W. Borinski] (*Physikal. Z.*, 1924, **25**, 19—21).—A study of the transformation of maleic ester in carbon tetrachloride solution, in presence of bromine, into fumaric ether, under the influence of energy of wave-lengths 557, 436, and 365 μμ, gave the following results :—(1) The photochemical efficiency at 18° with blue light (436 μμ) is 565, much greater than the figure calculated from the equivalent law. (2) The transformation is proportional to the number of absorbed quanta, but independent of the concentrations of bromine and solvent within wide limits; it is proportional to the quantum dimension at uniform temperatures, and increases for the same radiated energy exponentially with the temperature. These results appear contradictory, and seem to indicate that the activated molecule can survive several collisions. S. I. L.

Correlation of Additive Reactions with Tautomeric Change. II. Reversibility in Relation to the Stability of Carbon Chains. E. H. Ingold (Usherwood) (*J. Chem. Soc.*, 1924, **125**, 435—438).—Failure to obtain a homologue by the method which leads to the formation of the parent substance may be due to the structure of the homologue admitting of some retrograde additive reaction by which it can break down. The influence of homology on the reversibility of such addition reactions thus becomes the determining factor in the ability to exist of various types of carbon structure.

The influence of homology on the reversibility of the aldol addition process is very marked. Thus in the cases of acetaldehyde, *iso*butaldehyde, and α-methylbutaldehyde, the percentages of aldol present in the equilibrium mixtures at 25° and 62° are, respectively, 100, 92 and 39, and 41 and 9. The failure of Neustädter (A., 1907, i, 14) to obtain α-methylbutaldehyde must be ascribed to the experimental limitations imposed on the aldol reaction by the influence of temperature and structure on its reversibility. In the case of acetaldehyde, reversibility could not be detected at the ordinary temperature, and experiments at 60° were rendered impossible by the formation of crotonaldehyde.

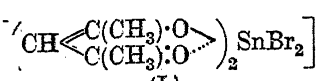
The position of the equilibrium, in the case of α-methylbutaldehyde, was determined by keeping the aldehyde or aldol, mixed with an equal volume of saturated aqueous potassium carbonate, in a closed vessel at a known temperature for a definite time, and working up as previously described (T., 1923, **123**, 1723), except that the distillation was finished at 125° in an atmosphere of carbon dioxide. *α-Methylbutaldol* forms a rather viscous, colourless liquid, b. p. 103—104°/6 mm., with a characteristic earthy odour.

F. G. W.

Dichloroacetaldoxime. O. ROUTALA and W. NEVVIUS (*Ber.*, 1924, **57**, [*B*], 252—254).—*Dichloroacetaldoxime*, $CHCl_2\cdot CH\!:\!N\cdot OH$, a colourless liquid with a penetrating odour, b. p. 67—69°/17 mm., 40—44°/2—3 mm. (partial decomp.), is prepared by the action of hydroxylamine hydrochloride on crude dichloroacetaldehyde obtained from trichlorolactic acid. It is converted by hydroxylamine at the atmospheric temperature into glyoxime. With phenylcarbimide, it yields the *compound*, $C_9H_8O_2N_2Cl_2,C_6H_6$, which darkens at 155° but has not a definite m. p. Attempts to transform it into the monoxime of glyoxal were not successful. H. W.

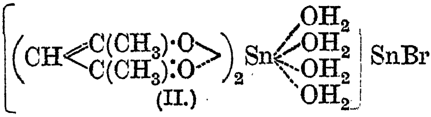
Condensation Products of Diethyl Ketone. J. B. EKELEY and M. S. CARPENTER (*J. Amer. Chem. Soc.*, 1924, **46**, 446—450; cf. Ekeley and Howe, A., 1923, i, 997).—The protracted action of an excess of diethyl ketone on sodium ethoxide at 10° leads to the production of a mixture of *homomesityl oxide* [*γ-ethyl-δ-methyl-Δ^γ-heptene-ε-one*], $CEt_2\!:\!CMe\cdot COEt$, and *homo*iso*phorone*, $C_{15}H_{28}O$. The former substance is a colourless liquid with a strong, mint-like odour and taste, b. p. 98—102°/20 mm., d_4^{20} 0·8535, n_D^{20} 1·4501. Homo*iso*phorone is a pale yellow, slightly viscous liquid, b. p. 137—140°/8 mm., d_4^{20} 0·91456, n_D^{20} 1·4831. A. B. S.

Residual Affinity and Co-ordination. XVII. Stannic Derivatives of β-Diketones. G. T. MORGAN and H. D. K. DREW (*J. Chem. Soc.*, 1924, **125**, 372—381).—The product of the reaction between molecular proportions of stannic chloride and acetylacetone in chloroform solution is a white, crystalline precipitate, m. p. 150° (decomp.), which deliquesces rapidly in air with formation of a crystalline substance, m. p. 98°. If instead of isolating this product, the reaction mixture is boiled with a second molecular proportion of acetylacetone, stannic bisacetylacetone dichloride, m. p. 202—203°, is obtained. This substance, contrary to Dilthey's statement (A., 1906, i, 342), is soluble in hot benzene, and its molecular weight in that solvent corresponds with the monomeric formula, $Sn(C_5H_7O_2)_2Cl_2$. The corresponding dibromide, obtained by the interaction of stannic bromide and copper acetylacetone in chloroform solution, does not react with stannic bromide when the two substances are dissolved together in anhydrous solvents, but the introduction of water leads to the formation of tetra-aquostannic bisacetylacetone stannibromide, $[(H_2O)_4Sn(C_5H_7O_2)_2]SnBr_6$. Stannic bisacetylacetone dibromide (I) and the tetra-aquo compound (II) exhibit co-ordination numbers of six and eight, respectively.



$$\left[\left(CH\!<\!\begin{matrix}C(CH_3)\cdot O\\ C(CH_3):O\end{matrix}\!>\right)_2 SnBr_2\right]$$

(I.)



$$\left[\left(CH\!<\!\begin{matrix}C(CH_3)\cdot O\\ C(CH_3):O\end{matrix}\!>\right)_2 Sn\!\begin{matrix}OH_2\\ OH_2\\ OH_2\\ OH_2\end{matrix}\right] SnBr_6$$

(II.)

The formation of stannic bis-β-diketone dibromides is a general reaction between stannic bromide and the copper salts of the β-diketones in chloroform, and proceeds according to the following equations: $3SnBr_4+3Cu\overline{Ac}_2=3Sn\overline{Ac}_2Br_2+3CuBr_2$; $3CuBr_2+Cu\overline{Ac}_2=2Cu_2Br_2+2\overline{Ac}Br$, where $\overline{Ac}$ is the univalent β-ketonic chelate group and $\overline{Ac}Br$ the corresponding bromo-β-diketone. The *cis-trans* (octahedral) isomerism theoretically possible has not yet been detected among these co-ordination compounds.

Stannic bisacetylacetone dibromide, transparent, colourless, lustrous, six-sided prisms, or aggregates of flaky crystals, m. p. 187°, separates from benzene as the double compound $[SnBr_2(C_5H_7O_2)_2]_2,C_6H_6$, which loses the solvent at 70—110°. *Tetra-aquostannic bisacetylacetone stannibromide*, obtained as described above or by the interaction of stannic bromide and stannic *bis*acetylacetone dibromide in presence of moisture, forms large, transparent, colourless prisms, m. p. 105—107°. When boiled with benzene, it loses water and dissociates into stannic bromide and the bisacetylacetone dibromide. *Stannic bisbenzoylacetone dibromide* is a white, microcrystalline powder, m. p. 213—214°, soluble in hot acetylacetone, with which it reacts to form benzoylacetone and the *bis*acetylacetone dibromide. 3-*Bromobenzoylacetone* was isolated as colourless prisms with an aromatic lachrymatory odour, m. p. 43—45°. *Stannic bisdibenzoylmethane dibromide*, shining, sulphur-yellow crystals, m. p. 276—278°, is only slowly hydrolysed by aqueous potassium hydroxide (40%) with formation of acetophenone. *Stannic bis-3-ethylacetylacetone dibromide*, transparent, colourless, six-sided prisms, m. p. 164—166° after softening at 162°, and 3-*bromo-3-ethylacetylacetone*, a pale yellow, lachrymatory liquid, b. p. about 195°, are described. F. G. W.

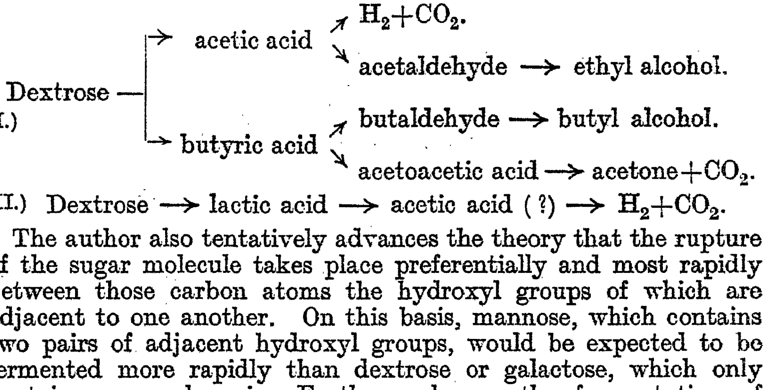
The α- and β-Forms of certain Monosaccharides. O. SVANBERG and K. O. JOSEPHSON (*Ber.*, 1924, **57**, [*B*], 297—299).—It is proposed to discriminate between the α- and β-forms of monosaccharides by observation of their differing affinity towards invertase. In the cases of dextrose and xylose, a distinct difference is observed in the behaviour of the two forms of the sugar; the α-variety of one sugar resembles exactly the β-variety of the other.

Amongst the monosaccharides, certain instances are encountered in which the more strongly dextro-rotatory variety (the α-form according to Hudson) can only be converted slowly, if at all, into the corresponding acetone-sugar, whereas in others (pentoses) the α-variety readily undergoes this change. When the α-sugar is very inert, the β-sugar is highly active.

The conclusions based on the two methods are identical in the cases of dextrose and xylose, but the available experimental data are insufficient to permit an extended proposal for the designation of α- and β-forms. H. W.

Molecular Configuration in the Sugars and Acid Production by *Bacillus Granulobacter Pectinovorum*. H. B. Speakman (*J. Biol. Chem.*, 1923, **58**, 395—413).—The non-volatile acid produced during the fermentation of starch by *Bacillus granulobacter pectinovorum* (cf. Reilly, Hickinbottom, Henley, and Thaysen, A., 1920, i, 465) has been identified as lactic acid, and the rates of formation of this acid, as well as those of acetic and butyric acids, during the fermentation of starch, arabinose, xylose, dextrose, galactose, and mannitol have been studied. From the results obtained, the fermentation of dextrose is provisionally regarded as taking place in two ways, according to the following schemes (cf. also A., 1920, i, 797):

(I.)



Dextrose
acetic acid
H_2+CO_2.
acetaldehyde → ethyl alcohol.
butyric acid
butaldehyde → butyl alcohol.
acetoacetic acid → acetone+CO_2.

(II.) Dextrose → lactic acid → acetic acid (?) → H_2+CO_2.

The author also tentatively advances the theory that the rupture of the sugar molecule takes place preferentially and most rapidly between those carbon atoms the hydroxyl groups of which are adjacent to one another. On this basis, mannose, which contains two pairs of adjacent hydroxyl groups, would be expected to be fermented more rapidly than dextrose or galactose, which only contain one such pair. Further, whereas the fermentation of dextrose should proceed mainly according to scheme (I), that of galactose should proceed mainly according to scheme (II). These deductions appear to be confirmed by experiment. Similar deductions from the configurations of the pentoses are also in accord with fact, but the theory appears to fail with respect to dulcitol, which, unlike mannitol, is not fermented by the bacillus (cf. also Robinson, A., 1922, i, 971). E. S.

Relations between Rotatory Power and Structure in the Sugar Group. I. The Halogenoacyl and Nitroacyl Derivatives of the Aldose Sugars. C. S. Hudson (*J. Amer. Chem. Soc.*, 1924, **46**, 462—477).—Investigations have been carried out with a view to determine the probable structure and physical constants of the as yet undiscovered α-halogenoacetylglucoses and related sugars as a help to their syntheses.

The application of van't Hoff's hypothesis of additive optical superposition to the two forms of dextrose penta-acetate permits the calculation of the rotation of the acetylated basal chain which is common to both varieties. If this value is subtracted from the known rotation of acetylbromoglucose, the numerical value for the halogenated carbon atom can be deduced. An extension of this method of calculation to a series of halogenoacetyl- and nitroacetylglucoses shows that the rotation of the terminal asymmetric carbon atom in these compounds is approximately a constant quantity for the various aldoses. A comparison of the calculated and observed values for a series of halogenoacetyl sugars, such as bromo- and chloro-acetyldextrose, indicates that they are to be classified as α-forms instead of, as previously, β-varieties.

Van't Hoff's theory is applicable also to the glucosamines and to derivatives of deoxyglucose. Bromoglucodesose tribenzoate (Bergmann, Schotte, and Leschinsky, A., 1923, i, 653), is an α-derivative whereas deoxymethylglucoside tribenzoate prepared from it is a β-form. Toluene-*p*-sulphonyltriacetylbromoglucose (Freudenberg and Ivers, A., 1922, i, 524) is also an α-variety, whereas the corresponding tetra-acetate and the methylglucoside belong to the β-series. A. B. S.

Relations between Rotatory Power and Structure in the Sugar Group. II. The Halogenoacetyl Derivatives of a Ketose Sugar [*d*-Fructose]. C. S. HUDSON (*J. Amer. Chem. Soc.*, 1924, **46**, 477—483; cf. preceding abstract).—The theory of optical superposition may be applied to ketoses, the effect of the halogenated terminal carbon atom being of the same magnitude as for the aldoses.

In the case of the two isomeric lævulose penta-acetates, the calculated values for $[\alpha]_D$ are —5° and —103° in chloroform, whereas the observed rotations of the two known isomerides are $[\alpha]_D^{20}$ +34·7° and —121° in the same solvent. It seems very unlikely that the dextrorotatory form is the expected α-derivative; possibly it has a different ring structure from the compounds hitherto examined. The other isomeride, $[\alpha]_D^{20}$ —121°, may be the β-form, although a difference of 18° causes doubt; the fact that normal β-bromo- and fluoro-acetyl-lævuloses can be prepared from it are evidence in favour of the β-modification. A. B. S.

Relations between Rotatory Power and Structure in the Sugar Group. III. The Biose of Amygdalin [Gentiobiose] and its Configuration. C. S. HUDSON (*J. Amer. Chem. Soc.*, 1924, **46**, 483—489).—The identity of the biose of amygdalin with gentiobiose is established by the observation that the rotation of the biose chain of amygdalin, as calculated from the rotations of two of its derivatives, *iso*amygdalin and prulaurasin, has the same value as the rotation of the chain of gentiobiose. The line of evidence is entirely independent of that of Haworth and Leitch (T., 1922, **121**, 1921) or Kuhn (A., 1923, i, 589). The combined results prove the configuration of gentiobiose to be that of 1 : 6-β-glucosidoglucose. Maltose and gentiobiose are the α- and β-glucos-

idic forms respectively of 1 : 6-glucosidoglucose; they constitute the first αβ pair of compound sugars to be definitely allocated.

Polysaccharides. XXII. Lichenase and Reserve Cellulose [Lichenin]. XXIII. The Separation of Lichenase into Constituent Enzymes. P. KARRER and others.—(See i, 471.)

Polysaccharides. XXIV. The Occurrence of Lichenin (Reserve Cellulose) in Lichens and other Plants. P. KARRER, M. STAUB, and J. STAUB (*Helv. Chim. Acta*, 1924, 7, 159—162).—The preparation of lichenin is described from the lichens *Evernia vulpina*, *Usnea barbata*, L., and *Parmelia furfuracea*, Ach.; it is shown to be identical with that from Iceland moss, *Cetraria Islandica*. It also occurs in many other plants, such as barley, oats, maize, spinach, beans, hyacinth bulbs and others. [Cf. i, 471.]
E. H. R.

Starch Iodide. A. LOTTERMOSER (*Z. angew. Chem.*, 1924, **37**, 84—85; cf. this vol., i, 269).—The partition of iodine between starch, aqueous potassium iodide, and carbon tetrachloride was determined, using the partition coefficient of iodine between carbon tetrachloride and *N*/10-potassium iodide (=1·16 at 25°). The partition of iodine between carbon tetrachloride, aqueous potassium iodide, and soluble starch was also examined by the potentiometer method (cf. A., 1922, i, 10). The results agreed with those obtained by ultrafiltration of the starch iodide solution and analytical determination of the individual components before filtration and in the ultrafiltrate. Starch iodide is thus shown to be an adsorption product. The I_3-ion is most strongly adsorbed, the adsorption curve being normal. At the same time, the I-ion and undissociated KI and KI_3 are also adsorbed, whilst the expulsion of free iodine from the surface generally increases with increasing concentration. The determination of the partition of iodine between benzene, water, and starch (cf. von Euler and Myrbäck, A., 1922, i, 527, 1120) gave unsatisfactory results owing to the uncertainty of the partition coefficient of iodine between benzene and water. Analogous experiments using carbon tetrachloride in place of benzene give results in agreement with those quoted above, so that there is no evidence of chemical combination between the iodine and starch. Adsorbed iodine is given up again very incompletely by starch, so that the curves obtained by adjusting the equilibrium from "above" and "below" do not coincide. The actual adsorption equilibrium is, however, rapidly attained, but the starch continues to adsorb iodine owing, apparently, to a very gradual diffusion of the latter into it.
W. T. K. B.

Starch-Iodine Reaction. N. R. DHAR.—(See ii, 242.)

Topochemical Reactions. Esterification and Mercerisation of Cellulose. R. O. HERZOG and G. LONDBERG (*Ber.*, 1924, **57**, [*B*], 329—332).—Röntgen examination shows that the esterification of ramie fibre and a number of varieties of artificial silk is a normal, heterogeneous process which proceeds from exterior to interior accompanied by solution of the cellulose esters. The progress of the reaction does not depend on the degree of arrangement of the crystallites, but on the previous chemical and physical treatment of the material. The nitration of cellulose, on the other hand, is a typical topochemical reaction occurring in the swollen fibre as in a homogeneous chemical system; denitration of cellulose nitrate under mild conditions takes place similarly.

Röntgen photographs of ramie or hemp fibres which have been mercerised without tension by sodium hydroxide solution (about 17%) and subsequently washed until free from alkali, exhibit Debye-Scherrer rings in place of the original point diagrams, showing that the crystallites have taken all possible positions. When the fibre is mercerised under such tension that the length remains unchanged, however, a point diagram is subsequently obtained, showing that the crystals lie, as originally, with the same axis in the direction of the fibre, that the crystals of mercerised cellulose have the same axial ratio and angles as the crystals of the original cellulose, and that the molecule of mercerised cellulose differs but little from that of the original cellulose, possibly to such an extent as is involved by the displacement of an oxygen linking.

H. W.

Quantitative Determination of the Fluorescent Powers (the Spectro-fluorescometry) of Cellulose and its Derivatives. S. J. Lewis (*J. Soc. Dyers and Col.*, 1924, **40**, 29—40).—The work previously described (A., 1923, ii, 334) has been extended and the methods have been improved so that the investigation of the fluorescent powers of cellulosic substances is now claimed to be easily carried out and even capable of application to industrial problems. Particularly, the spark source of ultra-violet light has been replaced by a cooled rotating tungsten arc, whereby the original feebleness of the spectrum between λ 2750—3300 and λ 2640—2730 is avoided, the necessary time for exposure has been shortened, and the method is about one thousand times more efficient, the accuracy being within 1%.

The fluorescent powers of various classes of cellulosic substances such as pure papers, pure cellulose, hydrocellulose, oxycellulose, and cellulose acetate have been determined in reference to a new standard (a specially purified paper) and the type of fluorescent curve for each class has also been determined. The previous conclusion that the fluorescent power of a cellulosic substance is independent of its physical condition has been confirmed. For instance, the fluorescent curves of cellulose acetate powder, paper, and transparent film are very similar, and the fluorescent power of oxycellulose is almost independent of its method of preparation.

Numerous curves representing the fluorescent powers of cellulose and related substances are given and discussed.

A. J. H.

The Viscose Reaction. B. Rassow and M. Wadewitz (*J. pr. Chem.*, 1923, **106**, 266—332).—A study has been made of the factors affecting the viscosity of solutions of viscose (cellulose xanthate). By the action of sodium hydroxide solutions on cellulose there appears to be formed a definite compound, having the empirical composition $C_6H_{10}O_5,NaOH$. When solutions containing less than 35% of sodium hydroxide are used, there is an equilibrium set up between cellulose, sodium hydroxide, the compound, and water. The compound is slowly decomposed by absolute ethyl alcohol. The so-called ripening of cellulose xanthate solutions, during which a fall in viscosity takes place, is probably the result of two reactions, the gradual hydrolysis of the cellulose xanthate and the disruptive action of the sodium hydroxide present on the cellulose molecular aggregates. [Cf. *B.*, 1924, 289.]

E. H. R.

Lignin. I. Flax Lignin and some Derivatives. W. J. POWELL and H. WHITTAKER (*J. Chem. Soc.*, 1924, **125**, 357—364).—Flax lignin, obtained from flax shoves by digestion with 10% sodium hydroxide solution at 130°, can be purified to a homogeneous, light brown product of the composition

$$C_{40}H_{30}O_6(OH)_5(OMe)_4{\cdot}CHO,$$

by pouring its solution in aqueous acetone into a large volume of dilute hydrochloric acid. Its *acetyl* derivative,

$$C_{40}H_{30}O_6(OMe)_4(OAc)_5{\cdot}CHO,$$

a dark brown, amorphous solid, is insoluble in cold, dilute sodium hydroxide, but is readily hydrolysed by boiling with water, indicating that the acidic properties of the lignin are to be ascribed to phenolic hydroxyl groups. By the action of methyl sulphate under very mild conditions, three methoxyl groups can be introduced into the lignin molecule, forming *methyl-lignin*,

$$C_{40}H_{32}O_8(OMe)_7{\cdot}CHO,$$

which is insoluble in alkali hydroxide and very resistant to hydrolysis. Attempts to acetylate the methylated product were not successful, indicating some difference between the remaining hydroxyl groups in lignin and those in its derivatives. The product of the action of hydriodic acid on the lignin agrees closely in composition with a demethylated lignin, but it cannot be acetylated, showing that reduction accompanies the demethylation. Cold, concentrated nitric acid, or a mixture of nitric and sulphuric acids, converts the lignin into a *trinitro* derivative, $C_{42}H_{39}O_{22}N_3$, a red powder which contains one methoxyl group and behaves as an aromatic nitro compound; six acetyl groups can be introduced, forming *acetylnitrolignin.* At higher temperatures, nitration is accompanied by much oxidation. The lignin reacts energetically with chlorine and bromine in absence of sunlight, with evolution of halogen acid. The products, *chlorolignin* and *bromolignin*, $C_{40}H_{20}O_8Hal_2(OMe)_2(OH)_5{\cdot}CHO$, are soluble in alkali hydroxides, and have suffered partial demethylation. They are not affected by hot nitric acid, and are only partly dehalogenated by boiling with sodium hydroxide solution, indicating that the remaining halogen atoms are attached to aromatic nuclei. *Acetylchlorolignin*, $C_{53}H_{42}O_{21}Cl_{12}$, and *acetylbromolignin*, $C_{42}H_{30}O_{16}Br_{12}$, as well as the acetylnitrolignins, are readily hydrolysed. The presence of one aldehyde group in the lignin molecule is deduced from the action of Fehling's solution and of phenylhydrazine. Comparison of these results with those of Cross and Bevan, Klason (A., 1908, i, 707; 1923, i, 187), and Beckmann and Liesche (A., 1921, i, 546; 1922, i, 233), shows that the lignins from jute, flax, and pine are not identical, but that those from flax and winter rye straw are closely related.

On treatment of the neutralised washings from the lignin (see above) with calcium chloride solution, considerable quantities of the calcium salt of a substance resembling lignin, but having a much smaller methoxyl content, are obtained. From the solution of chlorolignin in cold alkali hydroxide, acids precipitate the *compound* $C_{43}H_{35}O_{16}Cl_6$. F. G. W.

Potash Fusion of Lignin, Cellulose, and Wood. E. HEUSER and F. HERRMANN (*Cellulosechem.*, 1924, **5**, 1—6).—The observations of Heuser and Winsvold (A., 1923, i, 541, 900) on the fusion of lignin are confirmed and extended. When iron powder is present the yield of aromatic products is increased and the elimination of carbon dioxide from the protocatechuic acid is promoted, but not to such a large extent as when the fusion is performed in an iron crucible; iron is dissolved. There is only a slightly lower yield when the fusion is carried out at 240—260° instead of 270—280°. In the presence of ammonium carbonate a portion of the pyrocatechol is re-converted into protocatechuic acid. Fusion in an atmosphere of carbon dioxide instead of hydrogen does not have this effect; an atmosphere of carbon dioxide exerts a protective influence in suppressing the formation of oxalic acid, but not so completely as hydrogen. Carbon dioxide also moderates the total reaction, presumably because it combines with the potassium hydroxide; more lignic acid remains in the product. Carbon dioxide is produced to the extent of 27—28% of the weight of lignin when the fusion is carried out in a nickel crucible in the presence of air. Since the decomposition of protocatechuic acid into pyrocatechol is only pronounced in the presence of a catalyst in an atmosphere of hydrogen, the carbon dioxide formed under normal conditions is the result of oxidation at the expense of a portion of the products of reaction. Pure pyrocatechol is substantially resistant under the conditions employed. The fusion of cellulose with potash yields no aromatic products, only oxalic acid, with 21—22% of acetic acid and 1·5—2% of formic acid. The amount of oxalic acid is not substantially altered by the use of an atmosphere of hydrogen or by adding iron as catalyst; thus its formation from cellulose is not a process of oxidation. The fusion of wood gives results exactly compatible with those described for lignin and cellulose. J. F. B.

Nature of Lignin. E. STRUPP (*Cellulosechem.*, 1924, **5**, 6—7.)—The cyclo-saccharides or cycloses may be regarded as intermediate links capable of uniting partly with true carbohydrates and partly directly with one another. The presence of hydroaromatic rings in lignin and its undetermined position between the aromatic and aliphatic systems are cited as arguments in favour of the investigation of this conception. The methyl ether of inositol is a constituent of the cambial sap of certain conifers, and from inositol are obtainable several of the aromatic and aliphatic derivatives which have been detected in the products of decomposition of lignin. J. F. B.

Transformation of Ligneous Plant Substances into Coal. I. Production of Coal-like Products from Cellulose. C. G. SCHWALBE and R. SCHEPP (*Ber.*, 1924, **57**, [*B*], 319—322).—Cellulose can be converted into coal-like substances by salts which are present in sea water at a relatively low temperature and with surprising rapidity.

Coal-like substances, the composition and nature of which have not been fully examined, are produced from wood tissue and concentrated magnesium chloride solution at 150—180°, 135°, and 95°, respectively; a similar effect is produced by zinc chloride but not by calcium chloride solutions at 135°. Since in every case hydrochloric acid is produced it remains uncertain whether the effect is to be ascribed to dehydration or to hydrolysis of cellulose to dextrose and carbonisation of the latter. H. W.

Synthesis of some New β-Amino-acids, Esters, and Alcohols. R. BRECKPOT (*Bull. Soc. chim. Belg.*, 1923, **32**, 412—433).—Using three alkyl-substituted β-aminobutyronitriles described by Bruylants (A., 1923, i, 762) as a starting-point, the author has effected their hydrolysis and the esterification of the resulting acids, and has studied the reduction of these esters and also their reactions with magnesium ethyl bromide. The following compounds are described: β-*Dimethylaminobutyric acid hydrochloride*, hygroscopic needles, obtained by the action of concentrated hydrochloric acid on β-dimethylaminobutyronitrile, *chloroplatinate*, small orange crystals, m. p. 194—195° (decomp.). *Ethyl* β-*dimethylaminobutyrate*, b. p. 69·5°/12 mm., 183·5—184·5°/758 mm. (partial decomp.), d_4^{20} 0·91958, n_D^{20} 1·42641, prepared by the action of dry hydrogen chloride on an alcoholic solution of the hydrochloride of the acid, when an oil, $C_9H_{17}O_4N$, b. p. 105—110°/12 mm., which could not be identified, was produced simultaneously. The ester yields a *methiodide*, colourless needles, m. p. 127—128°, and a *chloroplatinate*, flattened orange-red prisms, m. p. 178—179° (decomp.), whilst on reduction with sodium and absolute alcohol, β-*dimethylaminobutyl alcohol*, b. p. 178—180°/760 mm., d_4^{20} 0·896, n_D^{20} 1·4408, is obtained. (The hygroscopic *methiodide*, m. p. 262—263°, and the non-crystalline *hydrochloride* are described.) The ester on treatment with magnesium ethyl bromide yields a mixture of diethylpropylenecarbinol, $CHMe{:}CH{\cdot}C(OH)Et_2$, and *αα-diethyl-γ-dimethylaminobutan-α-ol*, b. p. 205—212°, d_4^{20} 0·873, n_D^{20} 1·4410 (*methiodide*, m. p. 140—142°, *hydrochloride*, a white, extremely hygroscopic solid). β-*Ethylaminobutyric acid hydrochloride*, a crystalline mass, m. p. 72—73°, was also prepared by the action of hydrochloric acid on the corresponding nitrile; the corresponding free acid could not be prepared. *Ethyl β-ethylaminobutyrate*, b. p. 74°/12 mm., d_4^{20} 0·91549, n_D^{20} 1·42531 (*hydrochloride*, m. p. 111—114°), was obtained by passing dry hydrogen chloride through an alcoholic solution of the acid, with simultaneous production of a colourless oil, $C_{14}H_{27}O_6N$, b. p. 111—114°/19 mm. On reduction, the ester yields *β-ethylaminobutyl alcohol*, b. p. 187°, and is converted by treatment with magnesium ethyl bromide into the *lactam* of *β-ethylaminobutyric acid*, $CO<\begin{matrix}CH_2\\NEt\end{matrix}>CHMe$, b. p. 79·5—80·5°/12·5 mm., d_4^{20} 0·9420, n_D^{20} 1·4478 (*hydrochloride*, m. p. 72—73°); a theoretical explanation of its formation is given. At the same time, an octadiene, a colourless liquid, b. p. 127—130°/761 mm., and a small quantity of hygroscopic white needles, b. p. 255—265°, which were not identified, were produced. *Ethyl β-methylaminobutyrate*, b. p. 72°/12·5 mm., was prepared in a similar manner to its homologue; with magnesium ethyl bromide it yields the *lactam* of *β-methylaminobutyric acid*, b. p. 73—74°/12 mm., together with the same octadiene mentioned above.

The author points out that the three esters described may all be obtained from allyl bromide as a starting point (cf. Bruylants, A., 1922, i, 817), and the yields at each stage are good. H. J. E.

Salting-out of Amino-acids. P. Pfeiffer and O. Angern (*Z. physiol. Chem.*, 1924, **133**, 180—192).—*l*-Tyrosine, *l*-asparagine, *d*-glutamic acid, and glycylglycine are not salted out by ammonium sulphate and sodium acetate. Glycine and sarcosine are salted out to a greater or less degree by potassium acetate, *l*-cystine by ammonium sulphate, and *dl*-alanine by potassium acetate and ammonium sulphate. *l*-Leucine, *dl*-phenylalanine, and *l*-tryptophan are precipitated by sodium chloride, potassium acetate, and ammonium sulphate. S. S. Z.

Amino-acids and Polypeptides in Combination with Neutral Salts. IV. P. Pfeiffer, M. Klossmann, and O. Angern (*Z. physiol. Chem.*, 1924, **133**, 22—61).—Compounds of glycine, alanine, sarcosine, betaine, glycylglycine, alanylglycine, and di- and tri-glycylglycine, with a number of metallic salts, mainly alkali halides, were prepared and analysed. S. S. Z.

Oxidation of Amino-acids with Hydrogen Peroxide and at the Anode. F. Fichter and F. Kuhn (*Helv. Chim. Acta*, 1924, **7**, 167—172).—The oxidation of glycine in 2*N*-sulphuric acid solution, in presence of ferrous sulphate, with hydrogen peroxide proceeds partly according to the equation, $NH_2{\cdot}CH_2{\cdot}CO_2H+3O=NH_3+2CO_2+H_2O$, but only about half the theoretical quantity of ammonia and carbon dioxide can be accounted for. When insufficient hydrogen peroxide for the above equation is used, some formic acid is produced. When the oxidation is carried out in presence of ammonia, only minute amounts of carbamide are formed. By electrochemical oxidation of glycine in presence of ammonia, using ammonium nitrate as the electrolyte, larger quantities of carbamide are formed, and still larger quantities if ammonium carbonate is used instead of the glycine. It is concluded, therefore, that when glycine is used, the carbamide is formed from its decomposition products (cf. Fichter and Schmid, A., 1920, i, 824).

Oxidation of α-alanine with hydrogen peroxide in dilute sulphuric acid in presence of ferrous sulphate gives ammonia, acetaldehyde, acetic acid, formaldehyde, formic acid, and carbon dioxide; anodic oxidation in acid solution gives the same products. Anodic oxidation of leucine gives a mixture of *iso*valeraldehyde, *iso*valeric acid, *iso*butyric acid, acetone, acetic acid, formic acid, carbon dioxide, and ammonia. E. H. R.

Nitrogenous Components of Beetroot and Beetroot Products. E. O. von Lippmann (*Ber.*, 1924, **57**, [*B*], 256—258).—An account of experiments completed in 1902.

The following substances have been isolated from the solutions obtained after removal of sugar: *d*-arginine, m. p. 207°, $[\alpha]_D^{20}$ +11·25° in aqueous solution; *d*-lysine, m. p. 193·5°, $[\alpha]_D^{20}$ +15·42° when dissolved in water; *l*-histidine, m. p. above 280° (decomp.), $[\alpha]_D^{20}$ −39·48°; proline, m. p. 203°, $[\alpha]_D^{20}$ −3·12°; scatolecarboxylic acid, m. p. 162·5°; *l*-cystine, m. p. about 260° (decomp.), $[\alpha]_D^{20}$ +221° in hydrochloric acid solution (10%). The juice of freshly-harvested but still unripe beetroot yielded *l*-phenylalanine, m. p. 263°, a substance, $C_{18}H_{20}O_5N_2$, m. p. 275°, $[\alpha]_D^{20}$ +94·15° and +38·65° in faintly acidic and alkaline solution, respectively, which is probably identical with tyrosine anhydride (A., 1922, i, 184), and a substance, $C_6H_7O_4N$, colourless prisms, m. p. 125°, probably the imide of tricarballylic acid (cf. Thole and Thorpe, T., 1911, **99**, 1688). H. W.

Deamination of Esters of Alanine and Amino*iso*butyric Acid. A. L. Barker and G. S. Skinner (*J. Amer. Chem. Soc.*, 1924, **46**, 403—414).—*Ethyl α-amino*iso*butyrate hydrochloride*, m. p. 155—157° (corr.), is converted by a slight excess of sodium nitrite in aqueous solution at 0° into ethyl α-methylacrylate, ethyl α-hydroxy*iso*butyrate, and a little α-methylacrylic acid. Under similar conditions, methyl α-amino*iso*butyrate hydrochloride yields very small amounts of α-methoxy*iso*butyric acid which contains a small proportion of α-hydroxy*iso*butyric acid and α-methylacrylic acid together with methyl α-methylacrylate and methyl α-hydroxy*iso*butyrate. Methyl α-aminopropionate hydrochloride gives methyl acrylate, methyl α-chloropropionate, and methyl lactate, in addition to a non-volatile residue which is regarded as a pyrazolinedicarboxylic ester; the acidic products include α-methoxypropionic acid, lactic acid, and unsaturated and chloro acids. Ethyl α-aminopropionate hydrochloride yields ethyl acrylate, ethyl chloro- and hydroxy-propionates, ethyl diazopropionate, acrylic, lactic, α-chloropropionic, and α-ethoxypropionic acids, and certain nitrogenous residues which have not been identified. A. B. S.

Attempts to Prepare a Cyanide of Tin. J. G. F. Druce (*Chem. News*, 1924, **128**, 115—116).—No compound of tin with the cyanogen radical could be obtained by boiling an ethereal solution of stannous chloride with silver cyanide or ethyl cyanide. Freshly precipitated stannic hydroxide was dissolved in hot dilute hydrocyanic acid, and the filtered solution on evaporation in a vacuum left a pale brown, amorphous residue insoluble in water, alcohol, or ether. Analysis gave results closely agreeing with the formula $Sn(OH)_3{\cdot}CN$. Lead cyanide is produced by adding an excess of potassium cyanide to a saturated solution of lead nitrate; it is a white precipitate slightly soluble in hot 5% hydrocyanic acid, from which it crystallises in colourless needles. A. R. P.

Oxidation of Saturated Hydrocarbons by Ozone. R. Koetschau and W. Flemming (*Z. angew. Chem.*, 1924, **37**, 42—44).—Saturated cyclic hydrocarbons are attacked by ozone, as is shown by a marked increase in their viscosity and refractive index. The products obtained from decahydronaphthalene are mainly of the nature of peroxides which, unlike normal ozonides, dissolve in saturated hydrocarbons. When they are treated with water, hydrogen peroxide is formed, accompanied, not by aldehydic products, but by hydroxylic and carboxylic compounds. A small proportion of decahydronaphthol was identified in the reaction products, but the constitution of the peroxides and acids is still uncertain. The oxidation is far-reaching, and is complicated by the apparent partial rupture of the ring structure, with liberation of carbon dioxide. W. T. K. B.

Benzene and the Tetrahedron Formula. C. W. A. Lely (*Chem. Weekblad*, 1924, **21**, 114—117, 117—124).—Further arguments are quoted in support of the author's triangular formula (A., 1923, i, 99, 313, 767) and criticising the arguments brought against it by Olivier, van Roon, Schoutissen, and Derx and Hermans (*ibid.*, 195, 196, 451). The conclusion is drawn that the benzene formula of Kekulé and van't Hoff's tetrahedron conception of the carbon atom no longer serve to cover all the known facts. S. I. L.

Contact Condensation of Acetylene. N. Zelinsky.—(See i, 359.)

Hydrocarbons of Kerosene. C. R. Wagner.—(See i, 357.)

Action of Nitrogen Tetroxide on Aromatic Hydrocarbons, particularly Toluene. A. Schaarschmidt and E. Smolla (*Ber.*, 1924, **57**, [*B*], 32—42).—Nitrogen tetroxide scarcely reacts with cold benzene, more readily with toluene or xylene, immediately with mesitylene with evolution of heat. A study of the interaction of the tetroxide (1 part) and the hydrocarbon (3 parts) during extended periods at the atmospheric temperature, shows that benzene gives mainly nitrobenzene, picric acid, and some dinitrobenzene. *p*-Chlorotoluene is oxidised and nitrated to *p*-chlorobenzoic acid and nitro derivatives. Xylene and mesitylene are transformed into resinous products, oxidation occurring to a particularly marked degree in the case of mesitylene. Toluene is converted into oxalic acid (the yield of which increases greatly with prolongation of the action), benzoic acid, phenols, and benzaldehyde; the residue remaining after the product has been treated successively with water, sodium carbonate, sodium hydroxide, and sodium hydrogen sulphite consists mainly of almost equal proportions of unsaponifiable nitrotoluenes and readily hydrolysed nitrous or nitric esters of dinitrocresol. The unsaponifiable portion contains about 66% of mononitrotoluene; the remainder is a mixture of nitro products of higher boiling point, the least volatile of which decomposes explosively when heated in a vacuum at 200°. In the earlier stages of the reaction, acid, aldehydic, and neutral products are formed the weights of which are approximately in the ratio 3 : 2 : 4; when, however, the reaction is prolonged, the aldehydic components disappear almost completely in favour of the acid substances. The action depends greatly on the purity of the nitrogen tetroxide employed, and is most vigorous in the absence of water. H. W.

Reaction of Organo-Magnesium Compounds with Cupric Chloride. E. SAKELLARIOS and T. KYRIMIS (*Ber.*, 1924, **57**, [*B*], 322—326).—Diphenyl, 4 : 4′-ditolyl, 1 : 1′-dinaphthyl, and *s*-diphenylethane have been prepared by treating cupric chloride with the appropriate magnesium monoaryl halide (cf. Krizewsky and Turner, T., 1919, **115**, 559). Cupric chloride converts magnesium styryl bromide into $\alpha\delta$-diphenyl-$\Delta_{\alpha\gamma}$-butadiene, m. p. 147°, and magnesium *iso*amyl bromide into $\beta\eta$-dimethyloctane, b. p. 159—160°. Hydrodicamphene, m. p. 86°, is prepared from pinene hydrochloride. H. W.

Catalytic Effects of Zinc Chloride and Aluminium Chloride. J. F. NORRIS (*Ind. Eng. Chem.*, 1924, **16**, 184).—When the molecular compound of triphenylmethyl chloride and aluminium chloride is treated with ether, triphenylmethane is formed. This reaction is considered to proceed in the following way: $Ph_3C\cdot Cl+Et_2O=Ph_3C\cdot OEt+EtCl$; $Ph_3C\cdot OEt=Ph_3CH+MeCHO$. The first reaction is analogous to the action of aluminium chloride on a solution of benzoyl chloride in ether, the second reaction can be effected by heat alone, or in presence of aluminium chloride at the ordinary temperature. Triphenylmethane can therefore be prepared by allowing a mixture of carbon tetrachloride, benzene, and aluminium chloride to stand over-night; ether is then added, and after some hours the mixture decomposed with water. Excellent yields and a pure product are obtained. Primary alcohols are found to react readily with concentrated hydrogen chloride solution in presence of zinc chloride. This seems to indicate that the rôle of zinc chloride in reactions of this type is not that of a dehydrating agent, but of a catalyst operating by means of the formation of a molecular compound with the alcohol. C. I.

Hexaphenyl, the Linear Chain of Six Benzene Nuclei. R. PUMMERER and K. BITTNER (*Ber.*, 1924, **57**, [*B*], 84—88).—In continuation of previous work (A., 1922, i, 1196), 1-phenyl-

4-*p*-aminophenylbenzene is described in greater detail together with its transformation into hexaphenyl.

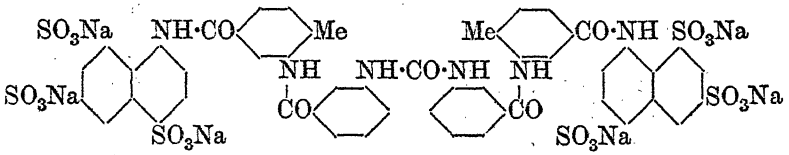
The preparation of 1-phenyl-4-*p*-aminophenylbenzene has been improved in many details; its success depends greatly on the purity of the reagents employed. 1-*Phenyl*-4-p-*acetamidophenylbenzene*, slender needles, m. p. 294°, 1-*phenyl*-4-p-*benzylideneaminophenylbenzene*, m. p. 262°, and the *compound*, $C_{28}H_{19}O_2N$, obtained from the base and *p*-naphthaquinone, are described. The amino compound yields a granular, yellow *diazonium sulphate* which is converted by potassium iodide into 1-*phenyl*-4-p-*iodophenylbenzene*, colourless leaflets, m. p. 247°. The action of silver powder on the iodo compound at about 330° leads to the production of *hexaphenyl*, $Ph{\cdot}[C_6H_4]_4{\cdot}Ph$, small, colourless, rhombic leaflets, m. p. 475°.

H. W.

Mechanism of the Reaction of *iso*Cyanates and *iso*Thiocyanates with the Grignard Reagent. H. Gilman and C. R. Kinney (*J. Amer. Chem. Soc.*, 1924, **46**, 493—497).—The reaction between phenyl *iso*cyanate and the Grignard reagent may be represented by the scheme : (I) PhN:C:O + PhMgBr → PhN(MgBr)·C(Ph):O → PhNH·C(Ph)O or (II) PhN:C:O+PhMgBr → PhN:C(Ph)OMgBr → PhN:C(Ph)OH, the last compound undergoing rearrangement to benzanilide. To decide between the two schemes, attempts were made to displace the MgBr in the additive compound by other radicals before hydrolysis. The introduction of methyl and ethyl groups was attempted, using methyl and ethyl sulphates, but the product obtained on hydrolysis was always benzanilide. The same occurred when diphenylmethyl chloride, triphenylmethyl chloride, methyl iodide, ethyl iodide, allyl bromide, and *p*-nitrobenzyl bromide were used. As the MgBr group is more easily replaced when attached to sulphur, the *iso*thiocyanates were investigated. When the Grignard compound was treated with methyl sulphate or ethyl sulphate, the products of hydrolysis were always *S*-methylthiobenzanilide and *S*-ethylthiobenzanilide, indicating that the addition of PhMgBr had taken place, not on the ·N:C:, but on the :C:S, group, the ·MgBr going to the sulphur. Scheme (II) represents the action in the case of the *iso*thiocyanates, and on account of the similarity of the *iso*cyanates, the same scheme probably represents the reaction in their case also.

A. B. S.

New Series of Trypanocidal Drugs. E. Fourneau, J. Tréfouël, (Mme.) J. Tréfouël, and J. Vallée (*Compt. rend.*, 1924, **178**, 675—676).—A substance (called 309) resembling Bayer 205 in all physical and trypanocidal properties, has been prepared. It is a grey or flesh-coloured powder, very soluble in water, insoluble in alcohol, and readily hydrolysed by concentrated sulphuric acid. Whilst 20-g. mice are completely unharmed by doses of 10—12 mg., mice infected with *Trypanosoma brucei* (Nagana) are cured by doses of 0·062 mg., infection of 2 days' standing being arrested by half this quantity. The drug is prepared as follows : sodium 1-naphthylamine-4 : 6 : 8-trisulphonate is condensed, in presence of sodium acetate, with 2-nitro-*p*-toluoyl chloride. The resulting nitro-compound is reduced, the amino compound obtained being condensed with *m*-nitrobenzoyl chloride. The product is reduced, and the amino compound formed condensed with carbonyl chloride. Bayer 205 (or the new compound, 309) is the sodium salt (following formula) of the resulting carbamide:



A large number of allied substances have been prepared, none of which has the physiological action of Bayer 205. The slightest constitutional change, *e.g.*, as obtained by using the above acid chlorides in the reverse order, is accompanied by complete suppression of trypanocidal action. E. E. T.

Compounds of the 2-Fluorenylmethyl Series. J. von Braun and H. Engel (*Ber.*, 1924, **57**, [*B*], 191—194; cf. A., 1923, i, 1087).—The cyano group of 2-cyanofluorene can be smoothly reduced to the methylamino group, without the occurrence of hydrogenation of the nucleus, by the action of hydrogen in the presence of nickel on a solution of the compound in decahydronaphthalene at 100°. 2-*Fluorenylmethylamine* and *di*-2-*fluorenylmethylamine* are thereby produced; they are separated from one another by taking advantage of the widely differing solubilities of the respective hydrochlorides in water. The primary base is a colourless, crystalline mass, m. p. 113°, b. p. 215°/10 mm.; the corresponding *hydrochloride*, m. p. 275—278° (decomp.), the *picrate*, m. p. 210°, the *acetyl* derivative, m. p. 171°, and the *phenylthiocarbamide* compound, colourless needles, m. p. 169°, are described. The secondary base, m. p. 147°, gives a *hydrochloride* which does not melt below 360° and a *nitroso* derivative, needles, m. p. 212°. Nitrous acid transforms the primary amine into 2-*fluorenylmethyl alcohol*, colourless crystals, m. p. 131°, which gives an intense bluish-green coloration with concentrated sulphuric acid; it is converted by the requisite phosphorus halide into 2-*fluorenylmethyl chloride*, m. p. 100°, and 2-*fluorenylmethyl bromide*, a pale yellow, crystalline mass, m. p. 95°. With trimethylamine, the bromide yields quantitatively 2-*fluorenylmethyltrimethylammonium bromide*, m. p. 218—219°, whilst when treated successively with hexamethylenetetramine and water, it is transformed into *fluorene*-2-*aldehyde*, colourless crystals, m. p. 174—175° (*semicarbazone*, m. p. 245—247°). 2-*Fluorenylacetonitrile*, m. p. 124°, is hydrolysed to 2-*fluorenylacetic acid*, m. p. 178°. H. W.

Kinetic Behaviour of Mixtures of Isomeric Nitrophenols on Reduction with Stannous Chloride. A. Klemenc (*Annalen*, 1924, **435**, 321—322).—The result obtained previously (this vol., i, 36) might have been due to the use of acid at only one concentration. The same result is now obtained varying this concentration, of which it is therefore independent. E. E. T.

Rôle of Weight of Acyl in the Migration from Nitrogen to Oxygen. L. C. Raiford and C. E. Greider (*J. Amer. Chem. Soc.*, 1924, **46**, 430—437; cf. Raiford, A., 1920, i, 156).—To investigate the influence of the weight of the acyl group on migration from nitrogen to oxygen, mixed diacyl derivatives of the three aminophenols were prepared, using the acetyl, benzoyl, and α-naphthoyl radicals. It is concluded that weight is the deciding factor and that migration is independent of substituents in the aminophenol nucleus. The heavier group is always found attached to nitrogen. o-α-*Naphthoylamidophenyl acetate* was obtained when *o*-acetamidophenol in pyridine solution was treated with the calculated quantity of naphthoyl chloride; it forms pink crystals, m. p. 133°. o-α-*Naphthoylamidophenol* is obtained when the acetate is allowed to stand in contact with a 1% solution of potassium hydroxide for 12 hours; very fine needles, m. p. 190°. The constitution of *o*-α-naphthoylamidophenyl acetate was proved by preparing *o*-α-naphthoylamidophenol from *o*-aminophenol and acetylating it, when the same substance was obtained. 5-*Bromo*-3-*naphthoylamido*-p-*tolyl acetate* was obtained from 5-bromo-3-acetamido-*p*-cresol by the same method as above; it crystallises in needles, m. p. 218°. 5-*Bromo*-3-*naphthoylamido*-p-*cresol* forms colourless needles, m. p. 151°. 4 : 6-*Dibromo*-2-α-*naphthoylamidophenyl acetate*, from 4 : 6-dibromo-2-acetamidophenol, crystallises in colourless needles, m. p. 226°. 4 : 6-Dibromo-2-α-naphthoylamidophenol, from the acetate by leaving it in contact with 2% alkali solution for 24 hours, crystallises in needles, m. p. 175°. It was also prepared by benzoylating 4 : 6-dibromo-2-aminophenol; the product was acetylated and identified with the acetate prepared as above. o-α-*Naphthoylamidophenyl benzoate* was obtained from *o*-benzoylamidophenol by the method described above, the yield being poor; it forms colourless needles, m. p. 176°. 4 : 6-*Dibromo*-2-α-*naphthoylamidophenyl benzoate*, from 4 : 6-dibromo-2-benzoylamidophenol, by the action of α-naphthoyl chloride, crystallises poorly, m. p. 235°. Its structure was proved by benzoylating 4 : 6-dibromo-2-α-naphthoylamidophenol, when the same substance was obtained. A. B. S.

Benzoylmethylcarbinol and Acetylphenylcarbinol. K. von Auwers and O. Jordan (*Biochem. Z.*, 1924, **144**, 31—43).—Benzoylmethylcarbinol has been prepared by the method of Auwers (A., 1918, i, 18), by hydrolysis of the acetyl compound with barium carbonate in water at 100°, and by hydrolysis of α-bromopropiophenone in aqueous alcohol solution with silver oxide. After purification by distillation in a vacuum, the refractive indices of the various preparations were measured, and these showed no alterations over a period of eight weeks. The purest preparation had n_D^{20} 1·5366, and was not affected by dilute acid or alkali nor by conversion to the acetyl compound and regeneration of the parent carbinol, which is therefore concluded to be a perfectly stable compound. The observations of Neuberg and Ohle (A., 1922, i, 480, 540) on the partial interchange of benzoylmethylcarbinol (α-ketol), Ph·CO·CH(OH)·CH_3, into acetylphenylcarbinol (β-ketol), OH·CHPh·COMe, also obtained biosynthetically by the action of the enzyme carboligase (A., 1921, i, 480), are therefore not confirmed. A mixture of these two compounds (α- and β-ketols) is obtained by the oxidation of α-phenylpropylene αβ-glycol (Zincke and Zahn, A., 1910, i, 316). Attempts to prepare acetylphenylcarbinol from methylbenzylcarbinol were unsuccessful, and the products obtained from phenylacetone (Carapelle, A., 1904, i, 158) consisted chiefly of derivatives of the α-ketol. The mechanism of this reaction is discussed. Finally, attempts to obtain acetylphenylcarbinol from methylbromobenzyl ketone by the action of silver oxide yielded a product (n_D^{20} 1·5152) to which the formula  $\mathrm{O}<\begin{array}{l}\mathrm{CHPh}\\ |\\ \mathrm{CMe{\cdot}OH}\end{array}$ or  $\mathrm{O}<\begin{array}{l}\mathrm{CPh{\cdot}OH}\\ |\\ \mathrm{CHMe}\end{array}$ is ascribed, on spectrochemical grounds, and since it does not react with semicarbazide. It is suggested that the slow change of refractive index observed by Neuberg and Ohle (*loc. cit.*) in their preparations may be due to the activity of spores normally present in a biochemical and absent from a chemical laboratory (cf. Auwers and Lange, A., 1922, i, 684).

The Presence of the Resorcinol Nucleus in the Tannin of Quebracho Wood. M. NIERENSTEIN (*Ber.*, 1924, **57**, [*B*], 356; cf. Einbeck and Jablonski, A., 1923, i, 1099).—Resorcinol has been obtained previously by the author from quebracho tannin (A., 1906, i, 761).

H. W.

Substitution Derivatives of Aurin. C. H. SPIERS (*J. Chem. Soc.*, 1924, **125**, 450—459).—Aurin is most readily isolated from corallin by saturating a solution of the latter in 60% alcohol with sulphur dioxide, and heating the precipitated compound of aurin and sulphurous acid at 130°. The aurin remaining may then be purified by fractional crystallisation from 60% alcohol. *Hexachloroaurin* is obtained as a red powder by boiling with water the product (probably hexachloroaurin sulphate) produced by the action of excess of sulphuryl chloride on aurin in glacial acetic acid solution in presence of ferric chloride. It is insoluble in the usual solvents, but crystallises from anisole in red crystals with a slight golden lustre. *Hexabromoaurin* is obtained similarly from its hydrobromide, which results from the action of excess of bromine on aurin in glacial acetic acid. It dissolves in *o*-chlorophenol, and the solution deposits the *compound* $C_{19}H_8O_3Br_6,C_6H_4Cl{\cdot}OH$ in red crystals with a brassy surface lustre. This loses *o*-chlorophenol at 120° in a vacuum, leaving pure hexabromoaurin as small, red crystals. *Hexabromodiacetylaurin*, obtained by the action of hot acetic anhydride on hexabromoaurin, and also in the cold when a trace of pyridine is present, forms yellow crystals, m. p. 280—290° (decomp.). *Hexabromotriacetylaurin*, colourless crystals of indefinite m. p.

(160—190°), is produced by the action of warm acetic anhydride on the diacetyl derivative in presence of pyridine. *Dibromoaurin* was obtained by the regulated action of bromine on a cold suspension of aurin in glacial acetic acid. It forms deep red, thin, interlocking prisms of a monohydrate, which loses water in a vacuum, leaving small, crimson crystals of the dibromoaurin. By the action of excess of iodine on a solution of aurin in sodium hydroxide, *tetraiododihydroxybenzophenone* (colourless crystals, m. p. 247°, decomp.) was the chief product, together with a little tri-iodophenol, and no iodoaurins could be isolated. *Tetraiododiacetyldihydroxybenzophenone* forms colourless crystals, m. p. 220—222°. *Trimethylaurin* was obtained by diazotising triaminotritolylmethane, and boiling the diazo compound with dilute sulphuric acid. It crystallises from a mixture of ethylene chlorohydrin and water in red crystals with a blue surface colour. *Tribromotrimethylaurin* is obtained by the action of bromine on a solution of trimethylaurin in boiling glacial acetic acid. It crystallises from ethylene chlorohydrin in reddish-brown needles with a slight golden lustre which contain 1 mol. of solvent. The latter is given up at 120° in a vacuum, leaving the tribromotrimethylaurin as small, red crystals. F. G. W.

Interaction of some Aromatic Hydrocarbons, Alcohols, and Aldehydes with Nitrogen Peroxide. L. W. BASS and T. B. JOHNSON (*J. Amer. Chem. Soc.*, 1924, **46**, 456—461).—Aromatic hydrocarbons show little tendency to interact with nitrogen peroxide at the ordinary temperature. Exposure to sunlight has very little effect. After heating or long exposure, there is slight evidence of nitration and oxidation. *o*-Nitrobenzaldehyde gave, besides *o*-nitrobenzoic acid, a compound which appears to be *o*-diazobenzoic acid nitrate. Benzyl alcohol was oxidised to a mixture of benzaldehyde and benzoic acid in about equal proportions. Aromatic aldehydes oxidised to acids. With *o*-, *m*-, and *p*-nitrotoluenes there was slight oxidation to *o*-, *m*-, and *p*-nitrobenzoic acids. Anthracene was partly oxidised to anthraquinone. A. B. S.

Chemical Nature of the Naphthenic Acids. I. N. ZELINSKY (*Ber.*, 1924, **57**, [*B*], 42—51).—An attempt has been made to settle the vexed question of the nature of the polycyclic ring present in the naphthenic acids. The latter were converted by a series of mild reactions into hydrocarbons containing the same number of carbon atoms. These were subjected to catalytic dehydrogenation (Zelinsky, A., 1911, i, 958; 1912, i, 167) under conditions such that hexamethylene derivatives were converted into hydrogen and aromatic hydrocarbons whereas the *cyclo*butane, *cyclo*pentane, and *cyclo*heptane rings remained unaffected. It was found that the great majority of the naphthenic acids are not derivatives of *cyclo*hexane.

[With A. TSCHUKSANOWA.]—The initial material was a series of fractions of naphthenic acids obtained from Baku petroleum. The acids were converted into their methyl esters, whereby it was found possible to isolate two fractions the analytical composition of which accorded with that required for methyl heptanaphthenecarboxylate and methyl octanaphthenecarboxylate, respectively, but the wide range of boiling point showed them to be mixtures of isomerides. They were reduced by sodium and alcohol to the corresponding primary alcohols, octanaphthene- and nonanaphthene-alcohols, which were converted by iodine and red phosphorus into the corresponding iodides and subsequently reduced by zinc dust in the presence of aqueous alcohols to the hydrocarbons. The latter were saturated, indifferent towards permanganate and concentrated sulphuric acid, and generally similar to *cyclo*hexane and *cyclo*pentane compounds. When passed over platinum black at 300°, they yielded very little hydrogen.

The preparation of *hexahydro*-o-*xylene* [1 : 2-*dimethyl*cyclo*hexane*], b. p. 127·5—128°, d_{20} 0·7903, d_4^{20} 0·7893, n^{20} 1·4321, is described incidentally; the physical constants of the compound differ widely from those of octanaphthene. H. W.

Chemical Nature of the Naphthenic Acids. II. N. Zelinsky and E. Pokrowskaja (*Ber.*, 1924, **57**, [*B*], 51—58).—An investigation of the octa-, nona-, and deca-naphthenecarboxylic acids along the lines indicated in the preceding abstract. The behaviour of nona-, deca-, and undeca-naphthenes towards palladium black at 300—310° shows that they cannot contain more than small amounts of derivatives of *cyclo*hexane. H. W.

Naphthenic Acids. IV. Metallic Salts of Naphthenic Acids. Y. Tanaka, K. Horiuchi, and G. Ôyama (*J. Chem. Ind. Japan*, 1923, **26**, 1190—1203).—Pure mixed naphthenic acids derived from the waste lyes from the refining of Kurokawa petroleum were separated by distillation into three fractions consisting chiefly of trideca-, tetradeca-, and pentadeca-naphthenic acids, respectively. Metallic salts of these fractions have been prepared, and their solubilities and some other properties have been studied. The solubility increases with decreasing molecular weight of the acid. The lead salts are transparent, resinous solids, m. p. 110—118°. Manganese tridecanaphthenate is a pink powder, soluble in ether, slightly soluble in absolute alcohol (about 2% at 15°), and practically insoluble in cold or hot water. This result contradicts that of von Kożicke and von Pilat (A., 1916, i, 814). Manganese tetradecanaphthenate melts at 61—63°. The lead and manganese salts have a drying action on linseed oil. Chromium salts were obtained in two different modifications, one being a violet powder and the other a green, viscous mass; the former is changed into the latter by heating. Aluminium naphthenate forms a transparent, colourless, and porous mass which can be powdered; it has a waterproofing action. The calcium salts are white, lustrous solids and the magnesium and zinc salts white powders. K. K.

Solid Constituents of Low-temperature Coal Tar. J. Marcusson and M. Picard (*Brennstoff-Chem.*, 1924, **5**, 68—69).—The solid carboxylic acids, isolated from low-temperature coal tar, may be divided into three classes, according as they are soluble in ether, insoluble in ether but soluble in acetone, or insoluble in ether or acetone. They are all aromatic in character and may be sulphonated and nitrated. The content of solid phenols in a tar varies with the method of distillation employed. Naphthalene or anthracene is not present in the primary tar, which contains up to 2% of solid paraffins, a considerable proportion of which is unsaturated. The acetyl value of the neutral portion of the tar both before and after hydrogenation was low, indicating that only small quantities of aldehydes and ketones were present. [Cf. *B.*, 1924, 287.] T. S. W.

Action of Esters on Magnesium Alkyl Halides. G. STADNIKOFF (*Ber.*, 1924, **57**, [*B*], 1—8).—An investigation of the abnormal course of the action of Grignard's reagents on esters whereby esters, ethers, and hydrocarbons are produced in addition to alcohols.

The formation of esters is attributed to the action of the iodomagnesium compounds of the alcohols, formed primarily, on the unchanged ester, thus: $2RMgI+R'\cdot CO_2Et \rightarrow R_2R'CO\cdot MgI+EtO\cdot MgI$ and $R_2R'CO\cdot MgI+R'\cdot CO_2Et \rightarrow R'\cdot CO_2\cdot CR_2R'+EtO\cdot MgI$. Under somewhat unusual conditions, a preparative method of obtaining the esters of complex alcohols is thereby afforded; the examples cited are benzhydryl acetate, b. p. 169—170°/11 mm., m. p. 40—42°, 3-methyl*cyclo*hexyl acetate, b. p. 187—188°/784 mm., menthyl formate, b. p. 110°/20 mm., menthyl acetate, b. p. 131°/40 mm., $[\alpha]_D$ —79·2°, menthyl benzoate, b. p. 189—190°/16 mm., m. p. 54·5—55°, *menthyl iminodiacetate*, $C_{24}H_{43}O_4N$, b. p. 263°/15 mm., m. p. 48—50°, and *menthyl cyanotriacetate*, $C_{36}H_{63}O_6N$, m. p. 80—81°. The iodomagnesium derivatives of the phenols do not react with esters.

The production of simple and mixed ethers is ascribed to the interaction of halogenomagnesium alkoxides on iodides or bromides in accordance with the scheme: $R\cdot O\cdot MgI+CHR'_2I \rightarrow MgI_2+R\cdot O\cdot CHR'_2$, whilst the iodides are themselves formed by the action of magnesium iodide on esters of alcohols of high molecular weight as exemplified by the scheme: $R\cdot CO_2CHPh_2+MgI_2=R\cdot CO_2\cdot MgI+CHPh_2I$. The small proportion of magnesium iodide normally present in a Grignard solution is sufficient to account for the change, since the material which enters into reaction is regenerated. If this explanation be accepted, it is to be expected that hydrocarbons would be formed when an excess of magnesium is employed as indicated by the scheme: $2CHPh_2I+Mg \rightarrow CHPh_2\cdot CHPh_2+MgI_2$. The following experimental evidence in favour of this interpretation is cited. Magnesium ethyl iodide when treated successively with benzhydrol and ethyl acetate in ethereal solution yields benzhydryl ethyl ether, b. p. 157—157·5°/14 mm., and dibenzhydryl ether, m. p. 108—109°. The same products with the addition of tetraphenylethane, m. p. 208—209°, are formed when ethyl acetate is replaced by ethyl formate; the yield of the hydrocarbon is increased by the use of an excess of magnesium. The iodomagnesium compound of triphenylcarbinol is converted to a small extent by ethyl acetate into triphenylmethyl ethyl ether, m. p. 84—85°; the intermediate production of triphenylmethyl iodide is placed beyond doubt by the isolation of triphenylmethyl peroxide from the products of the reaction.

When, in contrast to the usual conditions, the reaction between magnesium phenyl bromide and methyl benzoate is conducted vigorously, considerable amounts of triphenylmethyl methyl ether, m. p. 83—84°, are produced in addition to triphenylcarbinol. The formation of ethers can be considerably restricted, however, by a suitable choice of radicals. Thus magnesium phenyl bromide and benzyl benzoate give only a very small proportion of *triphenylmethyl benzyl ether*, m. p. 106—107°, in boiling ethereal solution, although the yield may be increased by working under increased pressure. Magnesium phenyl bromide and ethyl benzoate give triphenylcarbinol and triphenylmethyl ethyl ether in yields of 42% and 31%, respectively, whereas ethyl formate and magnesium phenyl bromide produce dibenzhydryl ether, benzhydryl ethyl ether, and tetraphenylethane.

Ethyl formate and magnesium α-naphthyl bromide give *di-α-naphthylmethyl ethyl ether*, $C_{23}H_{20}O$, m. p. 134—135°. H. W.

Condensation of Ethyl Oxalate with Nitrotoluenes. I. o-Nitrotoluene. W. WISLICENUS and E. THOMA (*Annalen*, 1924, **436**, 42—68).—By condensing *o*-nitrotoluene with ethyl oxalate in presence of potassium ethoxide, the authors have obtained *o*-nitrophenylpyruvic acid in a better yield (80 as against 55% of the theoretical) than resulted from Reissert's experiments (A., 1897, i, 417; 1898, i, 315). The product was first isolated as a *potassium* derivative, probably of the *aci*nitro form, $NO_2K{:}C_6H_4{:}CH{\cdot}CO{\cdot}CO_2Et$, a dark red substance. In aqueous solution, the colour gradually disappears and potassium *o*-nitrophenylpyruvate is formed. The two desmotropic forms of *o*-nitrophenylpyruvic acid were isolated. The *keto* form,

$$NO_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}CO{\cdot}CO_2Et,$$

was obtained by decomposing the above red potassium derivative in aqueous solution and formed needles or prisms, m. p. 46—47°. The *enol* form, $NO_2{\cdot}C_6H_4{\cdot}CH{:}C(OH){\cdot}CO_2Et$, m. p. 70—71°, was produced when the decomposition was carried out in ethereal suspension. In alcoholic solution, the two forms exist together as an equilibrium mixture containing 20% of enol, as determined by titration with bromine in the usual way. *Ethyl* β-*bromo*-o-*nitrophenylpyruvate*, obtained by brominating the enol, forms white crystals melting at about 76—82°. It regenerates the parent ester when treated with sodium bisulphite, and with aqueous or alcoholic alkali is partly transformed to a *compound*, $C_{16}H_{13}O_6N_2Br$, m. p. 121—122°. *Ethyl* o-*nitrophenylpyruvate phenylhydrazone* forms yellow needles, m. p. 103·5°, and the *oxime*, colourless needles, m. p. 121—122°. When the ester was treated with ammonia during 4 days, o-*nitrophenylpyruvamide*, $NO_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}CO{\cdot}CO{\cdot}NH_2$, colourless needles, m. p. 165—166°, was obtained. The ester reacts with aniline and various substituted anilines (but not with β-naphthylamine or methylaniline) to form *anils*. Thus with aniline, $NO_2\cdot C_6H_4\cdot CH_2\cdot C(:NPh)\cdot CO_2Et$, red prisms, m. p. 92°; with *p*-toluidine, dark red crystals, m. p. 90·5—91·5°; with *o*-toluidine, orange-red crystals, m. p. 77—78°; with *m*-toluidine, orange-red crystals, m. p. 138°; with 1 : 3 : 4-xylidine, red crystals, m. p. 106·5—107°; with *p*-bromoaniline, dark red prisms, m. p. 136—137°. These compounds should, however, be formulated as the tautomeric anilino-enols, as when they are brominated addition does not take place but bromine enters the nucleus (cf. Hantzsch, A., 1916, i, 12).

o-Nitrophenylpyruvic acid forms colourless leaflets, m. p. 121°. The *methyl* ester was obtained as yellow needles, sintering at 65° and melting between 83° and 87°. It appears to exist largely as the *enol* form, and the pure *keto* form was not isolated. Methylation of the ethyl ester with methyl sulphate gave exclusively *ethyl* o-*nitro-α-methoxycinnamate*, $NO_2\cdot C_6H_4\cdot CH:C(OMe)\cdot CO_2Et$, scales, m. p. 46—47°. This gave a *dibromide*,

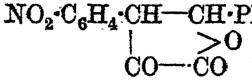
$$NO_2\cdot C_6H_4\cdot CHBr\cdot CBr(OMe)\cdot CO_2Et,$$

m. p. about 98°, which by boiling with alcohol was converted into *ethyl β-bromo*-o-*nitro-α-methoxycinnamate*, colourless prisms, m. p. 79—80°. o-*Nitro-α-methoxycinnamic acid* itself has m. p. 160—161°; its *methyl* ester, 67·5—68°. *α-Ethoxy*-o-*nitrophenylcinnamic acid* and its *methyl* ester were obtained in a similar way, using ethyl iodide as ethylating agent, and melted at 146—147° and 49—50°, respectively. When ethyl *o*-nitrophenylpyruvate was methylated with methyl iodide, the *C*-methyl derivative, namely *ethyl* o-*nitrophenyl-β-methylpyruvate*, was produced. This compound is an oil and was isolated as its *phenylhydrazone*,

$$NO_2\cdot C_6H_4\cdot CHMe\cdot C(:N\cdot NHPh)\cdot CO_2Et,$$

white needles, m. p. 131·5—132·5°; a by-product, presumably the phenylhydrazone of the dimethyl derivative, forms yellow scales, m. p. 136°.

Ethyl *o*-nitrophenylpyruvate was benzoylated to give the O-*benzoyl* derivative, $NO_2\cdot C_6H_4\cdot CH:C(OBz)\cdot CO_2Et$, small tablets, m. p. 46—47°. The corresponding *acetyl* derivative forms prisms, m. p. 95—96°. When the ester is treated with benzaldehyde the *lactone*,



$$\begin{array}{l} NO_2\cdot C_6H_4\cdot CH\text{—}CH\cdot Ph \\ \quad\quad\quad\quad | \quad\quad\quad > O \\ \quad\quad\quad\quad CO\text{—}CO \end{array}$$

, is formed, m. p. 174—176°, whilst with sodium nitrite, contrary to what Reissert has stated (*loc. cit.*), it yields *ethyl* o-*nitrophenyl*-β-iso*nitrosopyruvate*,

$$NO_2\cdot C_6H_4\cdot C(:NOH)\cdot CO\cdot CO_2Et,$$

colourless, tetrahedral crystals, m. p. 120·5—121·5° (decomp.). It combines with diazobenzene to form a yellow *compound*. Attempts to prepare ethyl *o*-nitrophenyl-β-methylpyruvate by interaction of ethyl oxalate and *o*-nitroethylbenzene failed.

II. Condensation of Ethyl Oxalate and p-Nitrotoluene. [With F. Schultz.]—This reaction was carried out in the same way as that just described, but when ethyl oxalate was used there were always formed some *pp'*-dinitrostilbene and dinitrodibenzyl as by-products (cf. Reissert, *loc. cit.*). These were not produced when methyl oxalate was used, nor from *p*-nitrotoluene and potassium or sodium ethoxide alone under the same conditions. *Ethyl* p-*nitrophenylpyruvate* forms a red *potassium* derivative resembling the *o*-isomeride described above. The free ester appears to exist solely in the enolic form as an intensely yellow substance, crystallising in rectangular prisms, m. p. 106°. The *acid* has m. p. 194° and gives a *pyridine* salt, yellowish-green needles, m. p. 150°. When the ethyl ester is reduced with tin and hydrochloric acid, it gives *p*-aminophenyl-lactic acid, m. p. 188° (Erlenmeyer, A., 1883, 994). *Ethyl* p-*nitrophenylpyruvate phenylhydrazone* forms yellowish-green prisms, m. p. 113°, and when heated with alcoholic sulphuric acid suffers intramolecular condensation, forming *ethyl* 3-p-*nitrophenylindole-2-carboxylate*, yellow, rectangular leaflets, m. p. 216°. The *anil* of ethyl *p*-nitrophenylpyruvate forms orange-red scales, m. p. 76°; the corresponding derivative with *o*-toluidine, orange-yellow needles, m. p. 85°; with *p*-toluidine, scarlet-red prisms, m. p. 97°; with α-naphthylamine, orange-red leaflets, m. p. 113°; with β-naphthylamine, scarlet-red, rectangular scales, m. p. 137°; with anthranilic acid, yellow needles, m. p. 194°. When the ester is treated with *o*-diamines quinoxalines are formed; thus with 1 : 3 : 4-tolylenediamine 2-*hydroxy*-3-p-*nitrobenzyl*-7-*methylquinoxaline* was obtained, m. p. 270°. With *o*-aminophenol 2-*keto*-3-p-*nitrobenzylbenzoxazine*, a deep red substance, m. p. 192°, was produced. By interaction of *p*-nitrotoluene and methyl oxalate, *methyl* p-*nitrophenylpyruvate* was prepared. This compound resembles the ethyl ester and crystallises in yellow pyramids, m. p. 149°. The β-*bromo* derivative has m. p. 114—115°, the *oxime*, 172—173°, and the *phenylhydrazone* about 136—145°.

III. Condensation of Ethyl Oxalate and 1-Nitro-2-methylnaphthalene. [With E. MUNDINGER.]—The sole product of this reaction under normal conditions was *ethyl* 1-*nitro*-2-*naphthylpyruvate*, but if double the usual quantity of potassium ethoxide were used 1 : 1′-*dinitro*-2 : 2′-*dinaphthylethane*, yellow prisms, m. p. 251°, was chiefly formed (cf. Mayer and Oppenheimer, A., 1916, i, 816). *Ethyl* 1-*nitro*-2-*naphthylpyruvate* was isolated in the two desmotropic forms. The *ketonic* form was obtained by decomposing its bisulphite compound and formed colourless needles, m. p. 84°. The *enol* was prepared by treating the potassium compound in ethereal suspension with mineral acid and separated as yellow crystals, m. p. 135°. In alcoholic solution, the two forms exist as an equilibrium mixture containing about 58% of enol. The ketonic form yields an additive *compound* with methyl alcohol, m. p. 76°. The ester forms a *copper* compound when treated with copper acetate, a brown precipitate, m. p. 182°. Its O-*benzoyl* derivative crystallised in yellow prisms, m. p. 107°; its O-*methyl* derivative in pearly prisms, m. p. 114—115°; the corresponding methoxy *acid* melts at 178°. The *anil* of ethyl nitronaphthylpyruvate forms yellow prisms, m. p. 116—117°. When the ester is treated with *o*-aminophenol an *oxazine* corresponding with the one described under II is formed (yellow prisms, m. p. 179°), and when it is reduced with zinc amalgam *ethyl* α-*naphthindolecarboxylate*

(m. p. 173—174°, free *acid*, m. p. 213°) is obtained (cf. Mayer and Oppenheimer, A., 1919, i, 17). W. A. S.

Studies in the Indene Series. I. Derivatives of Indeneglyoxylic Ester and of Indene-1-carboxylic Acid [Indene-3-carboxylic Acid]. W. Wislicenus and W. Hentrich (*Annalen*, 1924, **436**, 9—41).—Ethyl indene-1-glyoxylate,

$$\mathrm{CH}{<}\begin{matrix}\mathrm{C_6H_4}\\ \mathrm{CH}{-}{-}\end{matrix}{>}\mathrm{CH{\cdot}CO{\cdot}CO_2Et},$$

is methylated less readily than the corresponding fluorene derivative (see p. 398) and gives a product which cannot be isolated in a pure condition and was therefore directly hydrolysed; 55% of the calculated yield of 3-methylindene (b. p. 198·5°, d_4^{20} 0·9640) was thus obtained together with tarry by-products, transference of the double bond having occurred (cf. Courtot, A., 1915, i, 392). In the same way, 3-ethylindene was prepared; yield 43% of the theoretical, b. p. 215—216° (cf. von Braun, A., 1918, i, 111). The intermediate ethyl indeneglyoxylate could not be obtained in a pure state. 1-*Benzylidene*-3-*ethylindene* crystallises in yellow, rectangular scales, m. p. 57—58°. The *benzylidene* derivative of 3-benzylindene has m. p. 137·5°; the corresponding derivative from *p*-tolualdehyde forms bundles of yellow needles, m. p. 94°, and from cinnamaldehyde orange prisms, m. p. 161—162°. *Ethyl* 3-*benzylindene*-1-*glyoxylate* forms orange, rectangular tablets, m. p. 130°. This compound, unlike its congeners, is stable. 3-*Allylindene*, b. p. 138°/27 mm., prepared by the same general method, is very easily oxidised by the air. Attempts to prepare *s*-di-indenylethane failed.

Ethyl indeneglyoxylate behaves in a similar way to the corresponding fluorene compound when treated with primary amines (cf. p. 398). The *anil*, $C_9H_7C(:NPh){\cdot}CO_2Et$, forms brownish-red prisms, m. p. 142°; the *o*-toluidine derivative (unstable), dark brown prisms, m. p. 107—108°; the α-naphthylamine derivative, reddish-brown crystals, m. p. 127°. The *phenylhydrazone* forms dull yellow cubes, m. p. 69°; it decomposes when kept. The *oxime* forms a yellow, crystalline powder, m. p. 204° (decomp.).

When ethyl indeneglyoxylate reacts with one molecular proportion of hydrazine hydrate, an additive *compound* is formed to which the authors ascribe the formula $C_9H_7{\cdot}C(OH)(NH{\cdot}NH_2){\cdot}CO_2Et$. This is quite stable, m. p. 184°, and decomposes when heated above its melting point. When two molecular proportions of hydrazine hydrate were used the product was the *hydrazide* of the above, m. p. 218° (decomp.). Bromination of the ester gave a definite product only when four atomic proportions of bromine were taken up, 1 : 2 : 3-*tribromohydrindene*-3-*glyoxylic acid*, white rosettes, m. p. 101°, being formed. For this reason, attempts to determine the proportion of enol in ethyl indeneglyoxylate by Meyer's bromine titration method failed.

Ethyl indeneglyoxylate reacts with diazonium compounds, giving, not a hydrazone of the hitherto unknown indenone like the corresponding fluorene derivative (Wislicenus and Densch, A., 1902, i, 291), but a compound for which the structure  $CH{<}\substack{C_6H_4\\CH-}{>}C{<}\substack{CO\cdot CO_2Et\\N:NR}$ is proposed.

Ethyl 3-methylindene-1-glyoxylate gives a similar compound. This formula explains the fact that the compound dissolves readily in aqueous alkali with loss of the carbethoxy group. *Ethyl* 1-*benzeneazoindene*-1-*glyoxylate* forms dark red crystals, m. p. 146°. Similar products were obtained by interaction with *p*-nitrobenzenediazonium chloride (scarlet-red needles, m. p. 209°, decomp.), and with *m*-nitrobenzenediazonium chloride (red, amorphous powder, m. p. 201—202°, decomp.). From the latter an *acid* was obtained by dissolving it in cold dilute aqueous potassium hydroxide and reprecipitating, m. p. 151—153° (decomp.).

Indene-3-*carboxylic acid* was prepared by oxidising sodium indene-1-glyoxylate (Thiele, A., 1901, i, 76) with hydrogen peroxide (yield variable, 30—65%). The product melted at 160° and was found to be identical with that obtained by Weissgerber (A., 1911, i, 623). Transposition of the double bond has again taken place. The *hydrazide*, $C_9H_7\cdot CO\cdot NH\cdot NH_2$, forms rectangular, colourless leaflets, m. p. 186°; its *hydrochloride*, needles, darkens at 245° and decomposes at 263°. The hydrazide reacts readily with aromatic aldehydes, but not so smoothly with ketones, to give well crystallised *hydrazones*; thus with benzaldehyde, it forms white needles, m. p. 272—273°; with *o*-nitrobenzaldehyde, pale yellow needles, m. p. 215° (decomp.); with *p*-tolualdehyde, long, colourless needles, m. p. 254—255° (decomp.); with salicylaldehyde, flexible, yellow needles, m. p. 267° (decomp.); with cinnamaldehyde, sulphur-yellow leaflets, m. p. 239—242° (decomp.); with furfuraldehyde, yellow, rectangular, prismatic needles, m. p. 234°; with oxindole-3-aldehyde, yellow, clustered needles, darkening at 280°, m. p. 293° (decomp.). The *diacetyl* derivative of the hydrazide forms colourless needles, m. p. 147°; the *benzoyl* derivative, leaflets, m. p. 212—213°; a by-product, presumably the *dibenzoyl* derivative, has m. p. 253—255°. The β-*phenylhydrazide* of indene-3-carboxylic acid, $C_9H_7\cdot CO\cdot NH\cdot NHPh$, forms yellow needles, m. p. 188°. The *amide*, $C_9H_7\cdot CO\cdot NH_2$, forms yellow leaflets, m. p. 180°. The *anilide* crystallises in yellow prisms, m. p. 158°. Indene-3-carboxylic acid readily reacts with aldehydes in methyl-alcoholic potassium hydroxide solution to form highly coloured fulvene derivatives of the general formula,  $CO_2H\cdot C{<}\substack{C_6H_4\\CH-}{>}C:CHR$. 1-*Benzylideneindene*-3-*carboxylic acid* forms yellow needles, m. p. 222°; the 3-*furfurylidene* derivative, brownish-red, prismatic needles, m. p. 250°; the 3-*cinnamylidene* derivative is an orange powder, m. p. 235°. *Ethyl* 3-*carboxyindene*-1-*glyoxylate* forms orange-red prisms, m. p. 138·5° (decomp.). The *acid* forms a red precipitate, m. p. 199°. Its *ethyl* ester, obtained by interaction of ethyl indenecarboxylate with ethyl oxalate, crystallises in rectangular prisms, m. p. 116°. By treating the potassium derivative of potassium indene-3-carboxylate with ethyl bromide it was hoped to obtain 1-ethylindene-3-carboxylic acid, but actually the product was mainly 3-ethylindene. The potassium compound of ethyl indenecarboxylate reacts with two molecular proportions of benzenediazonium chloride, giving an orange-red *substance*, m. p. 163°. A similar compound with *p*-nitrodiazobenzene forms a red powder, m. p. 223—225° (decomp.).

Ethyl 3-methylindene-2-carboxylate (Thiele and Rüdiger, A., 1906, i, 586) reacts with ethyl oxalate in presence of potassium ethoxide to give *ethyl 3-methyl-2-carbethoxyindene-1-glyoxylate*, $CO_2Et{\cdot}C_9H_5Me{\cdot}CO{\cdot}CO_2Et$, the potassium compound of which forms pearly leaflets darkening at 200° and melting with decomposition at 215°. The free ester crystallises in pale yellow needles, m. p. 123—125° (only if rapidly heated). The corresponding compound from the methyl methylindenecarboxylate forms yellow needles, m. p. 134—135°.

II. Indene-3-carboxylic Acid. [With G. MANTHE.]—Methyl indene-3-carboxylate (Weissgerber, A., 1911, i, 623) on methylation readily gave (yield 66%) *methyl 1-methylindene-3-carboxylate*, a yellow oil, b. p. 127°/14 mm., which forms an unstable *dibromide*, m. p. 87—88°, b. p. 170—185°/11 mm. When the ester was hydrolysed 3-methylindene was obtained. In the same way, *ethyl 1-methylindene-3-carboxylate* was prepared (yield 80%, b. p. 132—136°/16 mm.) and likewise hydrolysed. *Ethyl 1-ethylindene-3-carboxylate* (yield 70%, b. p. 148—150°/19 mm.) gave similarly ethylindene in 70% yield. *Ethyl 1-benzylindene-3-carboxylate* (yellow, viscous oil, b. p. 240°/20 mm.) gave a good yield (80%) of benzylindene. Attempts to prepare by this method both *s*-di-indenylethane and 1 : 1′-di-indenyl failed. When the potassium compound of ethyl indenecarboxylate was treated with one molecular proportion of benzoyl chloride, a blue compound still containing potassium was produced, whilst when an excess of benzoyl chloride was used a *dibenzoyl* derivative was formed (yellow prisms, m. p. 166°). A similar derivative was produced when *m*-nitrobenzoyl chloride was used (yellow needles, m. p. 164°). The *dibenzoyl* derivative of the methyl ester forms a yellow powder, m. p. 182°. Indene-3-carboxylic acid, but not its ethyl ester, reacts with ethyl nitrate in presence of potassium ethoxide to give *di-potassium 1-nitroindene-3-carboxylate*,  $CO_2K{\cdot}C\Big<{}^{C_6H_4}_{CH\!-\!-}\Big>C{:}NO_2K$, of which the *lead* salt was also prepared.

III. 1-Nitroindene. [With K. PFEILSTICKER.]—Indene was treated with ethyl nitrate and potassium ethoxide and the hitherto unknown *1-nitroindene* obtained as a *potassium* derivative, $CH\Big<{}^{C_6H_4}_{CH\!-\!-}\Big>C{:}NO_2K$, an unstable, yellow, crystalline substance. The free nitroindene was obtained as a crystalline, greenish-yellow precipitate, m. p. 50°, which was too easily decomposed to be recrystallised. This is the *aci*-form. It decomposes without changing over into the true nitro compound. It forms more stable condensation products with aromatic aldehydes, but not with ketones, in presence of sulphuric acid. *3-Nitro-1-benzylideneindene* forms orange leaflets, m. p. 139°; *3-nitro-1-tolylideneindene*, red crystals, m. p. 105°; similar derivatives with p-*nitrobenzaldehyde* (red needles, m. p. 218—220°) and *cinnamaldehyde* (deep red crystals, decomposing at 208°) were prepared. Potassium nitroindene was converted by treatment with benzoyl chloride into 1-*nitro*-3-*benzoylindene*, yellow rhombs, m. p. 121°. The above benzylidene derivatives were reduced with tin and hydrochloric acid, giving the corresponding benzylaminoindenes. Nitroindene itself gave an unstable product. 1 : 3- (or 3 : 1-)*Benzylaminoindene* is a rapidly oxidising oil; its *hydrochloride*, microscopic crystals, m. p. 237°; its *acetyl* derivative, needles, decomposing at 243°. *Cinnamylaminoindene hydrochloride* melts at 242—245°, and its *acetyl* derivative decomposes at 267°. W. A. S.

Condensations in the Arylacetonitrile Series. I. Formyl-α-naphthylacetonitrile, Ethyl Formyl-α-naphthylacetate, and Ethyl α-Naphthyloxalacetate. W. Wislicenus, G. Butterfass, and G. Koken (*Annalen*, 1924, **436**, 69—100).—*Formyl-α-naphthylacetonitrile* was obtained by interaction of naphthylacetonitrile (Mayer and Oppenheimer, A., 1916, i, 816) and ethyl formate. The *potassium* compound forms a yellow powder. The free nitrile is an imperfectly crystalline, colourless mass, m. p. 130°, giving a brown *copper* salt. Titration with bromine indicated that from 95·8 to 99·7% (in different preparations) existed in the enolic form. It should therefore be formulated as hydroxymethylenenaphthylacetonitrile, $C_{10}H_7\cdot C(CN){:}CH\cdot OH$ (cf. Wislicenus, A., 1896, i, 522). It forms an *anilide*, white leaflets, m. p. 152—154°; p-*toluidide*, prisms, m. p. 142°; *semicarbazide*, diamond-shaped scales, m. p. 172—173°; and *hydroxylamide*, needles, m. p. 111°. It reacts with phenyl*iso*cyanate only at a much higher temperature than similar compounds (cf. Wislicenus, *loc. cit.*) to form the *carbanilate*, $NHPh\cdot CO\cdot O\cdot CH{:}C(C_{10}H_7)\cdot CN$, pale yellow needles, m. p. 158—159° (decomp.).

Various derivatives of ethyl formyl-α-naphthylacetate (Wislicenus and Elvert, A., 1917, i, 202) which could not be obtained directly by simultaneous hydrolysis and esterification of the nitrile, were prepared. The *anilide* forms quadratic prisms, m. p. 94—96°; the p-*toluidide*, glistening crystals, m. p. 90—91°. The latter derivative when heated at 250—260° suffered intramolecular condensation and 3-α-*naphthyl*-4-*hydroxy*-6-*methylquinoline* was formed (needles, m. p. 302—305°, subliming at a somewhat higher temperature; *picrate*, m. p. 140—145°). When ethyl formylnaphthylacetate was reduced by Clemmensen's method, it gave a mixture of α-(α-*naphthyl*)*hydracrylic acid* (crystalline powder, m. p. 112°) and *ethyl α-naphthylacrylate* (an oil, b. p. 220—230°/12 mm.). α-*Naphthylacrylic acid* forms needles, m. p. 152—154°. Ethyl formyl-α-naphthylacetate was alkylated and found to give invariably *O*-derivatives. The *methyl* derivative formed an indefinitely crystalline mass, m. p. 63—64°, and the *ethyl* derivative needles, m. p. 75°.

Ethyl α-naphthylacetate and ethyl oxalate were condensed together in the usual way to produce *ethyl α-naphthyloxalacetate*,

$C_{10}H_7\cdot CH(CO_2Et)\cdot CO\cdot CO_2Et$, a yellow oil which decomposes when distilled. Its *potassium* salt forms silky leaflets which decompose at 220—223°; its *copper* salt has a m. p. dependent on the solvent from which it is recrystallised. With phenylhydrazine, *ethyl* 1-*phenyl*-4-α-*naphthyl*-5-*pyrazolone*-3-*carboxylate* is obtained as microscopic leaflets, m. p. 213—214°. When the ester is heated at 180—186° it loses carbon monoxide, forming *ethyl α-naphthylmalonate* (clustered prisms, m. p. 59—60°), the sodium derivative of which, by interaction with ethyl bromoacetate and subsequent hydrolysis, gives *α-naphthylsuccinic acid*, rectangular scales, m. p. 206° (decomp.).

II. Formyl-β-naphthylacetonitrile and Ethyl Formyl-β-naphthylacetate. [With H. Riethmüller.]—The β-naphthyl derivative resembles the α-isomeride described above. It crystallises in leaflets, m. p. 181—182°, gives a brown *copper* salt, and appears to exist mainly in the *enolic* form. Its O-*benzoyl* derivative forms needles, m. p. 188°; the *anilide*, yellow needles, m. p. 185°; p-*toluidide*, yellowish-green leaflets and needles, m. p. 199—201°; *oxime*, leaflets, m. p. 135—136°; compound with *phenylcarbimide*, needles, m. p. 178° (decomp.). It reacts with benzenediazonium chloride to form β-*naphthylglyoxylonitrile phenylhydrazone* (yellow needles, m. p. 195—196°), the formyl group being displaced. When formyl-β-naphthylacetonitrile is treated with bromine, an impure *bromo* derivative, m. p. 162—164°, is obtained, whilst with iodine its potassium compound in methyl-alcoholic solution gives s-*di*-β-*naphthylsuccinonitrile*, $C_{10}H_7\cdot CH(CN)\cdot CH(CN)\cdot C_{10}H_7$, colourless prisms, m. p. 246—249°. The free nitrile in aqueous methyl alcohol with iodine and sodium hydroxide gives s-*di*-β-*naphthyldicyanoethylene*, $C_{10}H_7\cdot C(CN){:}C(CN)\cdot C_{10}H_7$, yellow needles, m. p. 204°. The latter compound was also obtained by treating β-naphthylacetonitrile in a similar way.

Ethyl formyl-β-naphthylacetate gave on reduction and hydrolysis the corresponding α-(β-*naphthyl*)-β-*hydroxypropionic acid*, $OH\cdot CH_2\cdot CH(C_{10}H_7)\cdot CO_2H$, which formed clustered crystals, m. p. 154—156°. Ethyl formyl-β-naphthylacetate gives an *anilide*, yellow needles, m. p. 91—92°; with phenylhydrazine it forms, not the expected phenylhydrazone, but 1-*phenyl*-4-β-*naphthyl*-5-*pyrazolone*, colourless needles, m. p. 219—220°, yet with 2 : 4-*dinitrophenylhydrazine* the second reaction does not take place and the corresponding *dinitrophenylhydrazone* only is formed, orange-yellow crystals, sintering at 110° and melting between 115° and 118°.

III. Ester Condensations with Benzyl Cyanide. [With H. Eichert and M. Marquardt.]—Cyanodeoxybenzoin,

$$C_6H_5\cdot CO\cdot CH(CN)\cdot C_6H_5,$$

was obtained by interaction of ethyl benzoate, benzyl cyanide, and metallic potassium in yields superior to those of earlier workers (Walther and Schickler, A., 1897, i, 522; Bodroux, A., 1911, i, 545). It forms colourless scales, m. p. 91—92°, and gives an *anil*, yellow needles, m. p. 201°. By simultaneous hydrolysis and esterification *ethyl benzoylphenylacetate* (needles, m. p. 90—91°; b. p. 220—225°/

13 mm.) and the corresponding *methyl* ester (rosettes of colourless prisms, m. p. 74—75°) were obtained. Both compounds exist in solution in the two desmotropic forms; in the case of the *methyl* ester, the enolic form accounts for 4—5% of the whole. Ethyl benzoylphenylacetate heated with aniline forms *benzoylphenylacetanilide*, Bz·CHPh·CO·NHPh, colourless needles, m. p. 168°; with phenylhydrazine it gives either the *phenylhydrazone* (needles, m. p. 173—174°) or, at a higher temperature, 1 : 3 : 4-*triphenyl*-5-*pyrazolone*, leaflets, m. p. 193—194°. When it was treated with phosphorus pentachloride, a mixture of 3-*chloro*-2-*phenylindone*,

$CCl<\begin{matrix}C_6H_4\\ CPh\end{matrix}>CO$

orange-red needles, m. p. 93—94°, b. p. 205—210°/13 mm., and *ethyl chlorobenzoylphenylacetate*, needles, m. p. 44—45°, b. p. 225—230°/12 mm., was formed. The latter compound was also obtained by direct chlorination of the ester.

Ethyl benzoylbenzoate (A., 1908, i, 994) was similarly condensed with benzyl cyanide to form *benzoylbenzoylphenylacetonitrile*, crystallising from alcohol in colourless needles or scales, m. p. 214°, and from benzene in irregular crystals, m. p. 188°. Neither is the enolic form. The compound resists hydrolysis, and forms a loose compound with hydrogen chloride. It is unaffected by hydrazine, aniline, and the like, and the only derivative obtained was *benzoylbenzoylphenylmethylacetonitrile*, $Bz{\cdot}C_6H_4{\cdot}CO{\cdot}CMePh{\cdot}CN$, prisms, m. p. 145°.

Ethyl *iso*butyrate and benzyl cyanide condensed to form *phenyl*iso*butyroacetonitrile* (β-*keto*-α-*phenyl*-γ-*methylvaleronitrile*),

$$CHMe_2{\cdot}CO{\cdot}CHPh{\cdot}CN,$$

a yellow oil, b. p. 154—156°/13 mm. The *bromo* derivative (needles, m. p. 192°), *phenylhydrazone* (needles, m. p. 109°), *hydrazone* (needles, m. p. 102°), *oxime* (needles, m. p. 85°), and *semicarbazone* (needles, m. p. 147°) were prepared. By simultaneous hydrolysis and esterification, *ethyl* α-*phenyl*iso*butyroacetate* (oil, b. p. 150—160°/13 mm.) and the corresponding *methyl* ester (leaflets, m. p. 52°) were obtained. The *acid*, $CHMe_2{\cdot}CO{\cdot}CHPh{\cdot}CO_2H$, forms colourless needles, m. p. 159°. From the ester with phenylhydrazine 1 : 4-*diphenyl*-3-iso*propylpyrazolone* (colourless needles, m. p. 191°) and with hydrazine 4-*phenyl*-3-iso*propylpyrazolone* (m. p. 192°) were obtained, whilst with semicarbazide, 4-*phenyl*-3-iso*propyl*-5-*pyrazolone*-1-*carboxylamide*,

$\begin{matrix}Pr^{\beta}C{:}N & — & N{\cdot}CONH_2\\ | & & |\\ CHPh & \cdot & CO\end{matrix}$

m. p. 187°, solidified again at 188—189°, remelted at 318—320°, was produced. When the ester was hydrolysed with dilute sulphuric acid, benzyl *iso*propyl ketone (b. p. 232—235°; cf. Blaise, A., 1901, i, 252) was obtained.

Ethyl diphenylacetate and benzyl cyanide condense to give *diphenylacetophenylacetonitrile* (β-*keto*-αγγ-*triphenylbutyronitrile*), $CPh_2{\cdot}CO{\cdot}CHPh{\cdot}CN$ (needles, m. p. 97°), which gives a *phenylhydrazone* (needles, m. p. 167°) and a *hydrazone* (needles, m. p. 135°). *Ethyl* β-*keto*-αγγ-*triphenylbutyrate* forms scales, m. p. 109—110°, and gives 4-*phenyl*-3-*diphenylmethyl*-5-*pyrazolone*, m. p. 232—233°, with hydrazine.

W. A. S.

Fluorene- and 2-Nitrofluorene-9-glyoxylic Esters. W. Wislicenus and H. Weitemeyer (*Annalen*, 1924, **436**, 1—9).—*Fluorene-9-glycollic acid*, which the authors (A., 1921, i, 511) failed to obtain from its ester, prepared by reducing ethyl fluorene-9-glyoxylate with aluminium amalgam, owing to simultaneous dehydration to dibenzofulvene-ω-carboxylic acid, is produced directly when the reduction is carried out by Clemmensen's method. *Methyl fluorene-9-glycollate* forms white needles, m. p. 96°. When ethyl fluorene-9-glyoxylate or the free acid is oxidised with hydrogen peroxide following Reissert's procedure, it gives, not the expected fluorene-9-carboxylic acid, but exclusively fluorenone. The product obtained by Wislicenus and Densch (A., 1902, i, 291) by methylating ethyl fluoreneglyoxylate is the *C*-methyl derivative, as it may be easily hydrolysed to 9-methylfluorene. Ethyl fluoreneglyoxylate may be nitrated: the glyoxylyl group is displaced and 2 : 9-*dinitrofluorene* formed. This substance crystallises in white needles which turn yellow on exposure to light, m. p. 136°. It decomposed when heated above its melting point, giving 2-nitrofluorene. The same compound was obtained, and its constitution proved, by further nitrating both 9-nitrofluorene (Wislicenus and Waldmuller, A., 1908, i, 973) and ethyl 2-nitrofluorene-9-glyoxylate. Although 9-nitrofluorene reacts with alcoholic potassium hydroxide, the 2 : 9-dinitro derivative is insoluble in this reagent and is unable to pass over into an *aci*-form. Ethyl fluorene-9-glyoxylate yields an *anil*, $C_{13}H_9\cdot C(:NPh)\cdot CO_2Et$, orange-yellow crystals, m. p. 137°, and corresponding derivatives with *p*-toluidine and β-naphthylamine (m. p. 156°). With hydrazine, on the other hand, the ethoxy group is displaced and a *hydrazide* formed, $C_{13}H_9\cdot CO\cdot CO\cdot NH\cdot NH_2$, small, yellow crystals, m. p. above 350°. This compound reacts with benzaldehyde to form a *benzylidene* derivative, crystallising in needles which decompose above 350°, and with acetone to give the *hydrazone*, $C_{13}H_9\cdot CO\cdot CO\cdot NH\cdot N:CMe_2$, m. p. 216°.

In 2-nitrofluorene, as in 2 : 7-dibromofluorene (Sieglitz, A., 1920, i, 605), the methylene group is more reactive than in fluorene itself. Thus when a warm solution of 2-nitrofluorene in benzene is added to a mixture of ethyl oxalate and potassium ethoxide, the potassium salt of 2-nitrofluorene-9-glyoxylic ester is immediately thrown down. *Ethyl 2-nitrofluorene-9-glyoxylate* forms yellow crystals, m. p. 143°. It gives coloured precipitates with heavy metals. The ester must be hydrolysed at temperatures below 80°, otherwise scission takes place and 2-nitrofluorene is reproduced. The free acid, $NO_2\cdot C_{13}H_8\cdot CO\cdot CO_2H,H_2O$, forms minute yellow crystals, m. p. 183°. The *methyl* ester has an indefinite melting point, about 120°. The ethyl ester yields a *phenylhydrazone*, yellowish-brown crystals, m. p. 192°; an *anil*, dark red crystals, m. p. 162°, and corresponding derivatives with *p*-toluidine and β-naphthylamine, m. p. 164° and 187°, respectively. Like the unsubstituted fluoreneglyoxylic ester, it gives a *benzoyl* derivative, $NO_2\cdot C_{13}H_7:C(OBz)\cdot CO_2Et$ (cf. Wislicenus and Densch, *loc. cit.*), minute yellow crystals, m. p. 137—138°, easily decomposed again by solution in alcoholic potassium hydroxide. W. A. S.

Equilibrium in the System, Sodium Phthalate–Sodium Sulphate–Water. H. W. FOOTE and S. B. SMITH (*J. Amer. Chem. Soc.*, 1924, **46**, 84—88).—The solubility relations of the system, sodium phthalate–sodium sulphate–water have been determined at 0°, 25°, and 35°. The transition temperature at the quintuple point, where the solid phases are anhydrous sodium sulphate, the decahydrate of sodium sulphate, and hydrated sodium phthalate, has been found to be 23°. When crystallised from water at the ordinary temperature, sodium phthalate has the composition represented by $2Na_2C_8H_4O_4,7H_2O$. J. F. S.

Unsaturated Lactones. S. GABRIEL, L. KORNFELD, and C. GRUNERT (*Ber.*, 1924, **57**, [*B*], 302—306).—An investigation of the behaviour of arylidene- and alkylidenephthalides containing a bromine atom in the side chain towards sodium methoxide.

α-*Bromobenzylidenephthalide*,  $CO<^{C_6H_4}_{O}>C{:}CBr\cdot Ph$, quadratic leaflets, m. p. 193°, is obtained by heating the corresponding dibromide in a current of carbon dioxide at 140—150° until hydrogen bromide ceases to be evolved. It is transformed by a solution of sodium in methyl alcohol into *hydroxydiketophenylhydrindene*,  $C_6H_4<^{CO}_{CO}>C(OH)Ph$, yellow needles, m. p. 192° (in a vacuum), which, when dissolved in alkali hydroxide and exposed to the air, passes into *benzil*-o-*carboxylic acid*, $COPh\cdot CO\cdot C_6H_4\cdot CO_2H$, m. p. 140—141°. *Methoxydiketophenylhydrindene* crystallises in needles, m. p. 114°. α-Bromobenzylidenephthalide is not appreciably affected by boiling water, but is transformed by boiling potassium hydroxide solution (20%) into benzhydroldicarboxylic acid, $CO_2H\cdot C_6H_4\cdot CPh(OH)\cdot CO_2H$.

α-Bromo-*p*-tolylidenephthalide is converted in a similar manner into 4′-*methylbenzil-2-carboxylic acid*, small needles, m. p. 143°.

α-*Bromopropiophenone*-o-*carboxylic acid*,

$$CO_2H\cdot C_6H_4\cdot CO\cdot CHBrMe,$$

needles, m. p. 110°, is transformed by potassium hydroxide into *hydroxydiketomethylhydrindene*, which readily becomes oxidised on exposure to air and by a saturated solution of hydrogen bromide in glacial acetic acid to the *dibromo* compound,

$$CO<^{C_6H_4}_{O}>CBr\cdot CHBr\cdot CH_3,$$

rhombic crystals, m. p. 97—99°. αα-*Dibromopropiophenone*-o-*carboxylic acid*, needles, m. p. 140°, when treated successively with boiling water and phenylhydrazine, gives a *phenylhydrazone*, $CO_2H\cdot C_6H_4\cdot CO\cdot C({:}N\cdot NHPh)\cdot Me$, or $CO_2H\cdot C_6H_4\cdot C({:}N\cdot NHPh)\cdot CO\cdot Me$, quadratic plates, m. p. 219° (decomp.).

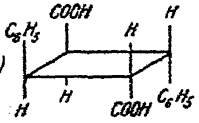
Phthalylideneacetic acid is converted by phosphoryl chloride and phosphorus pentachloride into *phthalylideneacetyl chloride*,  $CO<^{C_6H_4}_{O}>C{:}CH\cdot COCl$, long needles, m. p. 158°, which is transformed by a small quantity of the respective alcohols into the corresponding *methyl* ester, quadratic leaflets, m. p. 168° (decomp.), and *ethyl* ester, m. p. 132—134°; when boiled with an excess of the alcohols, however, it yields *methyl o-carboxybenzoylacetate*, $CO_2Me\cdot C_6H_4\cdot CO\cdot CH_2\cdot CO_2Me$, m. p. 73°, or the corresponding *ethyl* ester. *Methyl diketohydrindenecarboxylate*, $C_6H_4<\substack{CO\\CO}>CH\cdot CO_2Me$, is prepared by the action of potassium hydroxide solution at 0° on the dimethyl ester or of sodium methoxide on methyl phthalylideneacetate. The diethyl ester is converted similarly into ethyl diketohydrindenecarboxylate, m. p. 76°. H. W.

Fluorene Series. VIII. Synthesis of Fluorenone-1-carboxylic Acid. A. SIEGLITZ (*Ber.*, 1924, **57**, [*B*], 316—317).—2′-Aminobenzophenone-2-carboxylic acid is diazotised in sulphuric acid solution and the diazonium solution is warmed, thus giving anthraquinone, fluorenone, and fluorenone-1-carboxylic acid, m. p. 192—193° (cf. Mayer and Freitag, A., 1921, i, 248); the main product of the change, however, is *2′-hydroxybenzophenone-2-carboxylic acid*, colourless needles, m. p. 170—171°, which is converted by methyl sulphate and potassium hydroxide into *2′-methoxybenzophenone-2-carboxylic acid*, colourless crystals, m. p. 144—145°, and by concentrated sulphuric acid into 1-hydroxyanthraquinone, m. p. 191°. H. W.

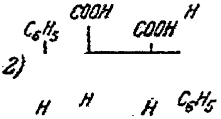
Synthesis of Depsides of *iso*Ferulic Acid [3-Hydroxy-4-methoxycinnamic Acid]. F. MAUTHNER (*J. pr. Chem.*, 1923, **106**, 333—335; cf. A., 1922, i, 936).—*Carbomethoxy*iso*ferulic acid*, obtained by the action of methyl chlorocarbonate on *iso*ferulic acid in alkaline solution, forms crystals, m. p. 223—224° (decomp.). It is converted by phosphorus pentachloride into *carbomethoxy*iso*ferulyl chloride*, colourless needles, m. p. 84°. With *p*-hydroxybenzoic acid, this gives p-*carbomethoxy*iso*ferulyloxybenzoic acid*, colourless crystals, m. p. 206—207°. The carbomethoxy group is removed by the slow action of ammonia in pyridine solution. The depside, p-iso*ferulyloxybenzoic acid*, forms colourless crystals, m. p. 217—218°. m-*Carbomethoxy*iso*ferulyloxybenzoic acid* forms colourless crystals, m. p. 203—204°, and m-iso*ferulyloxybenzoic acid*, colourless crystals, m. p. 191—192°. E. H. R.

Stereoisomerism of the Truxillic Acids and the Discovery of the Remaining Acid of this Group. VIII. R. STOERMER and F. BACHER (*Ber.*, 1924, **57**, [*B*], 15—23).—Theoretically five truxillic acids should exist, the configurations of which are shown by the formulæ:

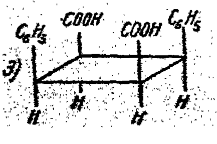
1)



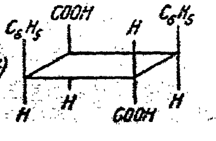
2)



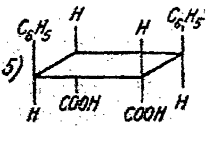
3)



4)



5)



The configurations 1 and 2 have been assigned definitely to α- and γ-truxillic acids respectively (cf. A., 1923, i, 929). ε-Truxillic acid is characterised as a *cis*-compound since it yields a unimolecular, crystalline imide from which it is smoothly regenerated. The *cis*-nature of η-truxillic acid follows from its ready conversion into the anhydride (cf. Stobbe and Zschoch, A., 1923, i, 337); since it is shown that the heavy groups lie on the same side of the *cyclo*butane ring, it is proposed to designate the compound *peri*-truxillic acid (configuration 3). The action of hydrochloric acid at 180° or of an excess of boiling sodium hydroxide on the *peri*-acid yields the outstanding member of the group, which is termed *epi*-truxillic acid owing to its production by a type of epimeric change. The conversion of the *epi*-acid by acetic anhydride into ε-truxillic acid (5) shows it to be a *trans*-compound to which the constitution 4 must necessarily be assigned.

The following individual compounds are described: *peri*-truxillic anhydride, prepared by a modification of the method of Stobbe and Zschoch (*loc. cit.*), m. p. 285°; *peri*-truxillic acid, m. p. 266° (decomp.) (Stobbe and Zschoch give m. p. 280°); *methyl* peri-*truxillate*, obtained by treatment of the acid with an ethereal solution of diazomethane or by the rapid action of methyl sulphate and alkali hydroxide, colourless crystals, m. p. 104—105°; *methyl hydrogen* peri-*truxillate*, from the anhydride and methyl alcohol at 180—200°, m. p. 192°; peri-(? epi-)*truxillamic acid*, small, quadratic plates or needles, m. p. 264° (decomp.); peri-*truxillanilic acid*, m. p. 247° (decomp.), from the *peri*-anhydride and boiling aniline whereby ε-truxilldianilide, m. p. 283°, is also produced; *methyl* peri-*truxillanilate*, m. p. 131°; *methyl* ε-*truxillanilate*, m. p. 159°; epi-*truxillic acid*, prepared most conveniently by heating the *peri*-acid with an excess of sodium hydroxide solution (10%), m. p. 285—287° (with transformation into ε-truxillic acid); *methyl* epi-*truxillate*, from the acid by means of diazomethane, methyl sulphate, or methyl-alcoholic hydrogen chloride, m. p. 111—112°; *methyl hydrogen* epi-*truxillate*, prepared by the partial hydrolysis of the normal ester with alcoholic potassium hydroxide solution, m. p. 204·5°. *epi*-Truxillic acid is converted by aniline at 190—210° into ε-truxilldianilide, and, apparently, a mixture of the two theoretically possible *epi*-truxillanilic acids which has not been separated satisfactorily into its components. H. W.

Formation and Ageing of Written Characters. The Primary Ink-salts of Iron Inks. F. ZETZSCHE, G. VIELI, G. LILLJEQVIST, and A. LOOSLI (*Annalen*, 1924, **435**, 233—264).—The primary ink salts have been prepared by the following method: the parent hydroxy compound (*e.g.*, salicylic acid) was treated with the theoretical quantity (see below) of a solution of ferrous sulphate in dilute sulphuric acid, the mixture neutralised with sodium hydroxide, and then shaken in an atmosphere of oxygen and carbon dioxide, until no more oxygen was absorbed. In the case of hydroxy compounds which are readily oxidised in alkaline solution (*e.g.*, pyrogallol), neutralisation was effected in the above oxygen–carbon dioxide atmosphere. In this manner, the formation of the ink salts can be followed and controlled, and that of secondary (oxidation) products avoided. The experimental procedure adopted follows very closely the mechanism of the formation of written characters.

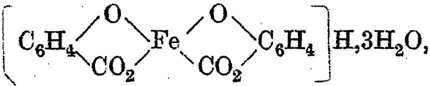
Gallic acid gives rise to *monogallatoferric* acid,

$$\left[\begin{array}{l}C_6H_2O_3 \\ CO_2\end{array} Fe\right]H,3H_2O,$$

a violet, microcrystalline powder, affording gallic acid on being treated with acids, dissolving in alkali to a blue, red, or yellow solution, according to the concentration, the latter solution being oxidised by air to give a yellow substance (galloflavine ?). The conversion of yellow, soluble ferrous gallate, $(C_6H_2[OH]_3\cdot CO_2)_2Fe$, into the above violet compound is reversed in presence of hydrogen and a platinum catalyst.

Using a greater proportion of ferrous sulphate to gallic acid, *ferric monogallatoferrate* (?),  $\left[C_6H_2\begin{array}{c}O_3\\CO_2\end{array}Fe\right]_3$ $Fe,12H_2O$, results, as a bluish-violet powder. It is readily oxidised, gives ferric oxide on heating at 85—90° and ferric hydroxide on treating with alkali.

Ferric disalicylate (*disalicylatoferric acid*),



$$\left[C_6H_4\begin{array}{c}O\\CO_2\end{array}Fe\begin{array}{c}O\\CO_2\end{array}C_6H_4\right]H,3H_2O,$$

red needles, gives a bluish-red solution in hot water, carbon dioxide being evolved on boiling. Unless care is taken in the preparation of this compound, Weinland's hexasalicylatotriferridisalicylatoferrate (cf. A., 1917, i, 649, and previous papers) is obtained. Alkali converts the disalicylate into alkali di- and trisalicylatoferrates.

Ferric protocatechuate,  $C_6H_3\begin{array}{c}O\\CO_2\end{array}Fe,3H_2O$, is a violet-blue, microcrystalline powder. The *ferric* salt of gallamide,

$$NH_2\cdot CO\cdot C_6H_2{:}O_3{:}Fe,2\cdot 5H_2O,$$

is a dark blue, microcrystalline powder; the *ferric* salt of gallanilide, $NHPh\cdot CO\cdot C_6H_2{:}O_3{:}Fe,3H_2O$, a dark violet powder and the *ferric* salt of ethyl gallate, $CO_2Et\cdot C_6H_2{:}O_3{:}Fe,2H_2O$, a dark blue powder. The last four compounds give wine-red solutions in aqueous alkali.

The *ferric* salt of tribromopyrogallol, $C_6Br_3{:}O_3{:}Fe,2H_2O$, is a dark blue powder, rapidly becoming brown owing to decomposition. The *diferric* salt of digalloylethyleneglycol,

$$\begin{array}{l}CH_2\cdot O\cdot CO\cdot C_6H_2{:}O_3{:}Fe,2H_2O\\ |\\ CH_2\cdot O\cdot CO\cdot C_6H_2{:}O_3{:}Fe,2H_2O\end{array},$$

is a bluish-violet powder, and the *triferric* salt of trigalloylglycerol, $C_{24}H_{11}O_{15}Fe_3,2H_2O$ (having a constitution similar to that of the glycol derivative) a bluish-violet powder, affording a red solution with alkali. The *pentaferric* salt of pentagalloyl-β-glucose, $C_{41}H_{37}O_{26}Fe_5,10H_2O$, and *pentaferritannate*, $C_{76}H_{37}O_{46}Fe_5,10H_2O$, have similar properties.

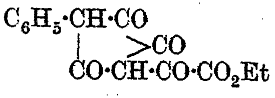
The proportions of phenolic compound to iron (mols. of phenolic compound : atoms of iron) in other primary ferric ink salts (which have not been actually isolated) are as follows: pyrocatechol (violet, 2 : 1), protocatechuic aldehyde (violet, 2 : 1), β-resorcylic acid (reddish-yellow, 1 : 1), gentisic acid (violet-red, 1 : 1), dibromopyrogallol (blue, 1 : 1), dibromogallic acid (dark blue, 1 : 1), and pyrogallolcarboxylic acid (dark violet, 1 : 1).

When ink is applied to paper, neutralisation of the acid present occurs first, followed by atmospheric oxidation of the ferrous salts, which are converted into bluish-violet insoluble primary ink salts (*e.g.*, of the gallic acid type). By the further action of atmospheric oxygen and moisture, the primary salts undergo oxidation, carboxyl or carbethoxyl groups being removed, with formation of carbon dioxide and brown secondary ink salts (*e.g.*, of the pyrogallol type). The black shade acquired by writing ink a week or so after use is due to the presence of a mixture of primary and secondary salts, or, in the case of salts rich in iron, to the presence, also, of ferric hydroxide. The addition of gum arabic to inks hinders atmospheric oxidation and loss of carbon dioxide.

Complete oxidation to the secondary ink salt type takes, on the average, twenty or thirty years. After a much longer time, ferric oxide or hydroxide alone will remain on the paper. E. E. T.

o-Cresoltetrachlorophthalein and some of its Derivatives. E. L. ARNOLD (*J. Amer. Chem. Soc.*, 1924, **46**, 489—493).—*o-Cresoltetrachlorophthalein* was prepared by condensing tetrachlorophthalic acid with *o*-cresol, using stannic chloride. It forms colourless crystals, m. p. 292—293° (decomp.). It resembles phenolphthalein and phenoltetrachlorophthalein, acting as an indicator, purple in alkaline solution; the end-point is between p_H 8·5 and 9. It forms a colourless *diacetyl* derivative, m. p. 207—208°, and a *dimethyl ether*, m. p. 212—213°. In concentrated sulphuric acid it gives a red solution probably due to sulphate formation. The spectrum of *o*-cresoltetrachlorophthalein in absolute ethyl alcohol is very similar to that of phenoltetrachlorophthalein, showing four weak bands in the ultra-violet, whereas that of phenolphthalein has only two bands, which correspond with the more prominent bands of the other two spectra. These bands are of frequency 3523 and 3613. A. B. S.

Ring Syntheses with Ethyl Oxalate. W. WISLICENUS and F. MELMS (*Annalen*, 1924, **436**, 101—112).—Continuing the work of Wislicenus and Schollkopf (A., 1917, i, 700), *ethyl triketophenylcyclopentaneglyoxylate* (annexed formula), was prepared by interaction of benzyl methyl ketone and ethyl oxalate (2 mols.) in presence of potassium ethoxide. This substance (yellow needles, m. p. 169—170°) is strongly enolised. It forms a red *di-potassium* salt and a dark red *copper* salt. The *acid* was obtained by mild alkaline hydrolysis as an orange powder, m. p. 214° (decomp.). When the ester was subjected to acid hydrolysis,



$$\begin{array}{l} C_6H_5\cdot CH\cdot CO \\ \quad\;|\qquad\;\; >CO \\ \quad CO\cdot CH\cdot CO\cdot CO_2Et \end{array}$$

scission took place and 2 : 4 : 5-*triketo*-1-*phenyl*cyclo*pentane* was formed, crystallising from benzene in yellow needles, from alcohol in colourless needles, whilst an orange modification was obtained when the compound was fused and again cooled, or boiled with water. All three forms melted at 167°. An aqueous solution of the substance is strongly acid to litmus and reduces Fehling's solution. The *phenylhydrazone* (only one keto group enters into these reactions) forms greenish-yellow scales, m. p. 241°, the *anil* orange-red scales, m. p. 172°, the p-*toluidine* derivative, red crystals, m. p. 195—196°. The *quinoxaline* formed by interaction with *o*-phenylenediamine forms brown needles, m. p. 251°. The methyl ether, 2 : 4-*diketo-5-methoxy*-1-*phenyl*cyclo*pentene*, in preparing which diazomethane was used, forms colourless crystals, m. p. 54—55°. The *benzylidene* derivative of triketophenyl*cyclo*pentane forms yellow crystals, m. p. 219°; similar derivatives with *p*-tolualdehyde (m. p. 206—207°) and *p*-nitrobenzaldehyde (m. p. 262—264°) were prepared; the latter is noteworthy in that the colour of the solution varies with the solvent employed. The *dibromo* derivative has m. p. 185°. When triketophenyl*cyclo*pentane was dissolved in alkali and reprecipitated, it was found to have been converted apparently into a *bis*-product of high melting point. A preliminary investigation of the condensations of ethyl β-ethoxyglutaconate, ethyl acetonedicarboxylate, and ethyl acetoacetate is described. W. A. S.

Polymorphic Forms and Thermotropic Properties of Schiff's Bases derived from 5-Iodo-4-hydroxy-3-methoxybenzaldehyde. R. M. Hann (*J. Washington Acad. Sci.*, 1924, **14**, 79—86).—Derivatives of the Schiff base type have been prepared from 5-iodo-4-hydroxy-3-methoxybenzaldehyde and aromatic amines. These 5-iodovanillidene compounds are not phototropic, but on vigorous trituration they change colour owing to the production of polymorphic forms. The introduction of iodine into *p*-hydroxy-*m*-methoxybenzaldehyde results in the disappearance of the power to undergo thermotropic change in the vanillidene derivatives. The following compounds are described: 5-*iodovanillideneaniline*, deep red bipyramids, changing to an orange powder, m. p. 152—153°; 5-*iodovanillidene*-o-*chloroaniline*, yellowish-brown crystals, m. p. 143°; 5-*iodovanillidene*-p-*chloroaniline*, red needles, changing to an orange powder, m. p. 110—111° (decomp.); 5-*iodovanillidene*-p-*bromoaniline*, yellowish-brown powder, changing to yellowish-green, with metallic lustre, m. p. 108° (partial decomp.); 5-*iodovanillidene*-p-*iodoaniline*, yellowish-brown powder, changing to yellowish-green with metallic lustre, m. p. 98°; 5-*iodovanillidene*-o-*toluidine*, light yellow needles, changing to deep yellow, m. p. 120—121°; 5-*iodovanillidene*-m-*toluidine*, orange-red granules, darkening on trituration, m. p. 103—104°; 5-*iodovanillidene*-p-*toluidine*, brilliant golden-yellow crystals, becoming nearly colourless on trituration, m. p. 160—161°; 5-*iodovanillidene*-α-*naphthylamine*, yellowish-brown crystals, changing to bright yellow, decomposes at 226°; 5-*iodovanillidene*-β-*naphthyl-*

amine, light yellow needles, changing to deep yellow, m. p. 163°; 5-*iodovanillidene-ψ-cumidine*, chocolate-brown powder, changing to yellow, m. p. 165°; 5-*iodovanillidenebenzidine*,

$C_6H_4I(OMe)(OH)\cdot CH:N\cdot C_6H_4\cdot C_6H_4\cdot NH_2$,

bright orange flocks, crimson on trituration, m. p. 160—161° (incipient decomp.). R. B.

o-Methoxydiphenylacetaldehyde and its Transformations. R. STOERMER and F. FRICK (*Ber.*, 1924, **57**, [*B*], 23—29).—αα-o-*Methoxydiphenylethylene glycol*, $MeO\cdot C_6H_4\cdot CPh(OH)\cdot CH_2\cdot OH$, long needles, m. p. 96°, prepared in moderate yield by the action of magnesium *o*-anisyl bromide on benzoylcarbinol, is smoothly converted by hot sodium hydrogen sulphite solution into o-*methoxydiphenylacetaldehyde*, a viscous liquid, b. p. 198°/16 mm.; the corresponding *semicarbazone* has m. p. 175°, whereas an oxime or a phenylhydrazone could not be isolated. The aldehyde is converted by glacial acetic and hydrobromic acids into 1-phenylcoumarone, m. p. 120°, instead of the expected 2-phenyl derivative. Probably the migration of the phenyl group takes place in an intermediately formed tolane derivative which could not be isolated. The aldehyde is transformed by phosphorus pentachloride into α-*chloro*-ββ-o-*methoxydiphenylethylene*, b. p. 190°/11 mm., which, however, is converted by sodium ethoxide at 200° immediately into 1-phenylcoumarone.

o-Methoxydiphenylacetaldehyde is decomposed by an excess of alcoholic potassium hydroxide solution at 180—200° into potassium formate and o-*methoxydiphenylmethane*, long, colourless needles, m. p. 30°, the constitution of which is established by its formation from *o*-methoxybenzophenone by Clemmensen's method; the corresponding *phenylurethane* has m. p. 115°. The methoxy derivative is converted by glacial acetic and hydrobromic acids at 150° into o-*hydroxydiphenylmethane*, b. p. 175°/18 mm., m. p. 15°.

The aldehyde is oxidised in acetone solution by potassium permanganate in the presence of potassium carbonate to o-*methoxydiphenylacetic acid*, m. p. 125°; it is reduced by aluminium amalgam in the presence of moist ether to o-*methoxydiphenylethyl alcohol*, a colourless, very viscous liquid, b. p. 220°/30 mm. (*phenylurethane*, m. p. 107°; *benzoate*, m. p. 98°), which is converted by acetic and hydrobromic acids into 2-phenylcoumaran, m. p. 39°, together with much resinous matter.

as-o-*Methoxydiphenylethylene oxide*, m. p. 90°, is obtained as a by-product of the preparation of αα-*o*-methoxydiphenylethylene glycol; it is transformed by dilute hydrochloric acid at 180° into methoxydiphenylacetaldehyde. H. W.

Action of Piperidine on Phenyl α-Bromostyryl Ketone. Production of a New Ketone, Phenylbenzylglyoxal. C. DUFRAISSE and H. MOUREU (*Compt. rend.*, 1924, **178**, 573—575; cf. A., 1922, i, 843; 1923, i, 113).—Piperidine converts phenyl α-bromostyryl ketone into *phenyl α-bromo-β-phenyl-α-piperidinoethyl ketone*, $COPh\cdot CBr(NC_5H_{10})\cdot CH_2Ph$, a pale yellow, sparingly soluble substance, m. p. 164°, very unstable, but forming stable salts with acids. This ketone, with 1 mol. of alkali in alcoholic solution, affords the red piperidinobenzylideneacetophenone described by Watson (T., 1904, **85**, 1322) and now shown to be phenyl α-piperidinostyryl ketone, $COPh\cdot C(NC_5H_{10}){:}CHPh$. The latter substance, on hydrolysis by acid, is converted into *phenylbenzylglyoxal*, $Bz\cdot CO\cdot CH_2Ph$, a pale yellow solid, m. p. 67—68°, unstable in air, but stable in a vacuum. E. E. T.

Additive Compounds of Metallic Salts and Doubly Unsaturated Aromatic Ketones. W. DILTHEY and O. RAUCHHAUPT (*Ber.*, 1924, **57**, [*B*], 309—310).—Concentrated solutions of di-*p*-methoxystyryl ketone and ferric chloride in glacial acetic acid yield the additive *compound*, $[(OMe\cdot C_6H_4\cdot CH{:}CH)_2CO]_2,FeCl_3$, dark violet needles, m. p. 146° after previous decomposition. In a similar manner, o-*chlorostyryl methoxystyryl ketone*, yellow crystals, m. p. 109°, gives the *compound*, $C_{36}H_{30}O_2Cl_4Fe$, dark violet needles, m. p. 155—156° (decomp.). Uranyl chloride and distyryl ketone yield the product, $[(CHPh{:}CH)_2CO]_2,UO_2Cl_2$, small, golden-yellow leaflets, m. p. 264° after incipient decomposition at 200°; the corresponding *compound*, $C_{38}H_{36}O_8Cl_2U$, from di-*p*-methoxystyryl ketone, crystallises in violet-red, hexagonal leaflets, m. p. about 258° (incipient decomp. 150°). The additive *compound*, $[(C_6H_4[OMe]\cdot CH{:}CH)_2CO]_2,VCl_2$, brownish-yellow needles, is prepared from its components dissolved in glacial acetic acid.
H. W.

Synthesis of Nitranilic Acid. H. O. MEYER (*Ber.*, 1924, **57**, [*B*], 326—328).—Nitranilic acid [3 : 6-dinitro-2 : 5-dihydroxy-*p*-benzoquinone] is obtained in 72—78% yield by the action of fuming nitric acid (*d* 1·459) on *p*-benzoquinone at −5° to −10°. It crystallises in lemon-yellow needles, m. p. 86—87°, whereas Nietzki (A., 1911, i, 69) gives m. p. 100°. The potassium salt, $C_6O_8N_2K_2$, exists in two distinct crystalline forms. The *rubidium* salt, $C_6O_8N_2Rb_2$, yellow needles, is described. H. W.

Action of Potassium Ferricyanide on Purpurin in Alkaline Solution. R. SCHOLL and P. DAHLL (*Ber.*, 1924, **57**, [*B*], 80—83).—Purpurin is readily oxidised in alkaline solution by potassium ferricyanide at the atmospheric temperature to *o*-phthalic acid and 2 : 5-dihydroxy-*p*-benzoquinone, *o*-2 : 5-dihydroxy-*p*-benzoquinonoylbenzoic acid being apparently produced initially. The first stage of the oxidation of purpurin is therefore similar to that of alizarin (Scholl and Zinke, A., 1919, i, 25; 1920, i, 169) and quinizarin (this vol., i, 178). Dihydroxyanthraquinones which contain the hydroxy group attached to different nuclei and monohydroxyanthraquinones are not affected by potassium ferricyanide in alkaline solution at the atmospheric temperature. The hypothesis that oxidative fission occurs through the diquinones therefore receives further support.

In addition to the orange-yellow modification described in the literature, 2 : 5-dihydroxy-*p*-benzoquinone exists in a pale yellow, metastable *modification* which is stable only in the presence of acetic acid. The substance is readily converted by methyl-alcoholic hydrogen chloride into the dimethyl ether. H. W.

Dyestuffs of the Phenanthrene Series. K. Brass (*Z. angew. Chem.*, 1924, **37**, 67—69).—Phenanthraquinonyl azides behave in a similar manner to phenyl azides towards sulphuric acid. Thus, 2-azidophenanthraquinone yields 2-amino-3-hydroxyphenanthraquinone, from which 2 : 3-dihydroxyphenanthraquinone is prepared in the usual manner, some 2-aminophenanthraquinone being formed at the same time. Under certain conditions 4-azidophenanthraquinone yields, with sulphuric acid, 4-amino-1-hydroxyphenanthraquinone, and under others 1 : 4-dihydroxyphenanthraquinone. These compounds are dyestuffs for wool and cotton. The presence of a hydroxyl group in the *o*-position to an amino- or a hydroxyl group has little or no effect on the tinctorial properties of the parent compounds, whereas its presence in the *p*-position to such groups greatly enhances their value. As mordant dyestuffs the 4-amino-1-hydroxy and 1 : 4-dihydroxy compounds are more powerful than the 2-amino-3-hydroxy and 2 : 3-dihydroxy compounds. The simple aminophenanthraquinones are also dyestuffs for wool, and possess more powerful tinctorial properties than the simple aminoanthraquinones. [Cf. *B.*, 1924, 246.]
W. T. K. B.

Azido-, Aminohydroxy-, and Dihydroxy-phenanthraquinones. I. K. Brass, E. Ferber, and J. Stadler (*Ber.*, 1924, **57**, [*B*], 121—128).—2-Aminophenanthraquinone behaves as an amine of the benzene series, in which the basic character is repressed by the presence of acidic groups; its diazotisation and the conversion of its diazonium hydrogen sulphate into a series of derivatives are described.

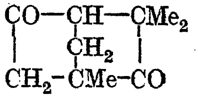
2-Aminophenanthraquinone is conveniently diazotised in accordance with the method of Schmidt and Soll (A., 1908, i, 996), somewhat less advantageously in the presence of concentrated sulphuric acid. *Phenanthraquinone-2-diazonium perbromide*, $C_{14}H_7O_2N_2Br_3$, orange-yellow crystals which lose bromine at the atmospheric temperature, is prepared by treating a solution of the diazonium sulphate with an excess of bromine dissolved in potassium bromide solution. It is transformed by ice-cold ammonia solution (25%) into 2-*azidophenanthraquinone*, cinnabar-red leaflets, m. p. 186° (decomp.) after darkening at 175°, which is converted by *o*-phenylenediamine hydrochloride into 2-*azidophenanthraphenazine*, $C_{20}H_{11}N_5$, long, yellow needles, m. p. 190° (decomp.) after softening at 180°. The action of sulphuric acid on the azide gives a mixture of 2-aminophenanthraquinone and 2-*amino*-3-*hydroxyphenanthraquinone*, bluish-black needles, which softens at 120°, but does not melt in a capillary tube at a higher temperature. The mixture of products yields phthalic acid when oxidised. 2 : 3-*Dihydroxyphenanthraquinone*, prepared by diazotisation of the hydroxy-amine in concentrated sulphuric acid solution, crystallises in slender, reddish-brown needles which have no definite melting point; it yields a *mono-sodium* salt and a *quinoxaline* derivative, small, orange-yellow needles, m. p. 162° (decomp.). H. W.

Azido-, Aminohydroxy-, and Dihydroxy-phenanthraquinones. II. K. Brass and J. Stadler (*Ber.*, 1924, **57**, [*B*], 128—136).—4-Aminophenanthraquinone is converted by sodium nitrite in the presence of concentrated sulphuric acid into the corresponding diazonium salt, which is relatively unstable in comparison with phenanthraquinone-2-diazonium sulphate (preceding abstract). It is transformed by a solution of bromine in concentrated potassium bromide solution into *phenanthraquinone*-4-*diazonium perbromide*, an orange-red, crystalline powder, from which 4-*azidophenanthraquinone*, red needles, is obtained by the action of aqueous ammonia (10%). 4-*Azidophenanthraphenazine*, prepared from the azide and *o*-phenylenediamine hydrochloride, crystallises in slender, yellow needles, m. p. 197° (decomp.). 4-Azidophenanthraquinone reacts with dilute sulphuric acid with unexpected ease, and after prolonged treatment at the temperature of boiling water yields solely 1 : 4-*dihydroxyphenanthraquinone*, very slender, bluish-violet needles (1 : 4-*diacetoxyphenanthraquinone*, prisms, m. p. 183°; 1 : 4-*dihydroxyphenanthraphenazine*, brownish-red, lustrous needles, m. p. 288°). The attachment of the two hydroxy groups to the same benzene nucleus is established by the observation that phthalic acid is the only isolable product of its oxidation. The compound must therefore be either 1 : 4- or 3 : 4-dihydroxyphenanthraquinone, and, since the latter constitution has already been assigned to morpholquinone, from which the present compound is quite distinct, the former alternative is selected. It appears, however, to be quite exceptional for a substituent to enter the phenanthraquinone nucleus in the 1-position. Oxidation of 1 : 4-dihydroxyphenanthraquinone in ethereal solution with silver oxide or lead tetra-acetate leads to the formation of a yellow op-*diquinone* which has not been isolated in the homogeneous condition.

4-*Amino*-1-*hydroxyphenanthraquinone* is prepared by the action of sulphuric acid on the azide at a temperature not exceeding 90°. It crystallises in violet-black aggregates of needles, decomp. 218° after subliming at 165°. The *sulphate* and the *hydrochloride* are described; the *sodium* salt is hydrolysed by water. It is transformed by hot, dilute sulphuric acid into 1 : 4-dihydroxyphenanthraquinone. H. W.

Formation of Diketocamphane (Ketocamphor) and of Diketofenchane (Ketofenchone) by the Oxidation of Camphor and Fenchone with Chromic Acid. J. Bredt (*J. pr. Chem.*, 1923, **106**, 336—347).—The *p*-diketocamphane described by Bredt and Goeb (A., 1921, i, 257) has now been obtained by the oxidation of both natural and inactive synthetic camphor with chromic acid. The product in both cases melts at 210° and the yield is only 4—5% of the theoretical. In its physiological action, *p*-diketocamphane is similar to camphor, and it has the advantage of greater solubility in water.

By oxidation of fenchone in glacial acetic acid solution with chromic acid below 15° (the reaction takes about 5 weeks), *ketofenchone* is obtained, probably having the annexed formula. It forms long, thin needles, m. p. 42·5—43°, has a typical lactone odour, and is readily volatile in steam; b. p. 108°/10·5 mm. The new keto group is more active than the original keto group of fenchone, and there are readily formed a *monophenylhydrazone*, white needles, m. p. 149—150° (decomp.), and a *monosemicarbazone*, thin needles, m. p. 222—223°. Ketofenchone has $[\alpha]_D^{21}$ +75·78° in benzene. E. H. R.



Solubility of Sulphur in Caoutchouc. W. J. KELLY and K. B. AYERS (*Ind. Eng. Chem.*, 1924, **16**, 148—150).—The distribution of dissolved sulphur between unvulcanised rubber and amyl or *n*-butyl alcohol obeys Henry's law. The sulphur consequently is present in the rubber in a state of solution and not of adsorption. For the determination of the solubility of sulphur in rubber it is convenient to suspend strips of the latter in a saturated solution of sulphur in butyl alcohol in the presence of solid sulphur; when equilibrium is attained, the dissolved sulphur is extracted from the rubber with acetone and its amount determined. [Cf. *B.*, 1924, 266.] D. F. T.

Reduction Products of 1-Acylcoumarones. R. STOERMER, C. W. CHYDENIUS, and E. SCHINN (*Ber.*, 1924, **57**, [*B*], 72—80).—1-Acetylcoumarone, b. p. 136°/11 mm., m. p. 76° (cf. Stoermer and Schäffer, A., 1903, i, 846), is prepared conveniently by the action of chloroacetone on salicylaldehyde and potassium hydroxide dissolved in alcohol; the *phenylhydrazone*, pale yellow crystals, m. p. 153—154°, and the *semicarbazone*, colourless needles, m. p. 217°, are described. Reduction of the ketone by sodium amalgam in the presence of alcohol acidified with acetic acid yields coumaranylmethylcarbinol,  $C_6H_4\genfrac{<}{>}{0pt}{}{O}{CH_2}CH{\cdot}CHMe{\cdot}OH$, and *acetylcoumarane*,  $C_6H_4\genfrac{<}{>}{0pt}{}{O}{CH_2}CHAc$, a colourless liquid, b. p. 132—133°/12 mm. (the sodium hydrogen sulphite *compound*, the *oxime*, m. p. 111—112°, the *phenylhydrazone*, yellow leaflets, m. p. 113°, and the *semicarbazone*, m. p. 192°, are described). *Diacetylbiscoumarane*, $C_{20}H_{18}O_4$, m. p. 183°, gives a *mono-oxime*, m. p. 177°. Reduction of acetylcoumaraneoxime by sodium amalgam and alcohol leads to the formation of small quantities of 1-*α-aminoethylcoumarane*,  $C_6H_4\genfrac{<}{>}{0pt}{}{O}{CH_2}CH{\cdot}CHMe{\cdot}NH_2$, a fairly mobile liquid, b. p. 153°/15 mm. (*hydrochloride*, colourless, lustrous leaflets, m. p. 117—118°; *picrate*, yellow leaflets, decomp. 209°).

Reduction of acetylcoumarone with sodium and alcohol according to the method of Stoermer and Schäffer (*loc. cit.*) gives acetylcoumarane, coumaranylmethylcarbinol, and *o*-hydroxyphenylbutan-γ-ol, m. p. 66—67°; the latter substance may also be obtained by reduction of coumaranylmethylcarbinol. It is converted by bromine in chloroform solution into 4-*bromo*-2-*hydroxyphenylbutan*-γ-*ol*, long, colourless needles, m. p. 94—95°. o-*Methoxyphenylbutan*-γ-*ol*, a colourless, viscous liquid, b. p. 143°/12 mm., is prepared by the action of methyl iodide and potassium hydroxide on an alcoholic solution of the corresponding phenol. It is converted by zinc chloride at 150° into *o*-Δ^{β}-butenylanisole, b. p. 104—106°/12 mm., d_4^{19} 0·9721, n_D^{19} 1·5255 (cf. von Braun and Schirmacher, A., 1923, i, 286), which is isomerised when heated with a small quantity of potash-lime to o-Δ^{α}-*butenylanisole*, b. p. 106—108°/12 mm., d_4^{18} 0·9819, n_D^{18} 1·5346.

1-iso*Propenylcoumarane*,  $C_6H_4{<}\substack{O\\CH_2}{>}CH\cdot CMe{:}CH_2$, a mobile liquid, b. p. 106—108°/12 mm., is obtained together with much resinous matter by the action of magnesium methyl iodide on acetylcoumarane.

1-Benzoylcoumarone, m. p. 90—91° (*semicarbazone*, m. p. 137°), is conveniently obtained by the action of bromoacetophenone and potassium hydroxide on salicylaldehyde in alcoholic solution. Somewhat unexpectedly, it is reduced by sodium and alcohol mainly to 1-*benzylcoumarane*, m. p. 26°, b. p. 185°/15 mm.; small quantities of β-o-*hydroxyphenylethylphenylcarbinol*,

$$OH\cdot C_6H_4\cdot CH_2\cdot CH_2\cdot CHPh\cdot OH,$$

slender needles, m. p. 94° (*phenylurethane*, m. p. 124°; *diphenylurethane*, m. p. 52°), are simultaneously produced. *Coumaronylphenylcarbinol*,  $C_6H_4{<}\substack{O\\CH}{\geqslant}C\cdot CHPh\cdot OH$, m. p. 76°, is obtained by the reduction of benzoylcoumarone with sodium amalgam in acid-alcoholic solution at the atmospheric temperature; the corresponding *phenylurethane* has m. p. 126°. *Benzoylcoumarone-oxime*, m. p. 132°, is reduced by sodium amalgam in faintly acid, alcoholic solution to *coumaronylphenylaminomethane*, a colourless liquid, b. p. 200°/11 mm. (*hydrochloride*, m. p. 210°). It is converted by one molecular proportion of sodium nitrite into coumarylphenylcarbinol and by two molecular proportions into benzoylcoumarone; it is reduced by sodium and alcohol to benzoylcoumarane. 1-*Benzylcoumarone*, b. p. 180—185°/15 mm., cannot be prepared from the benzoyl compound by Clemmensen's method, but is obtained when the hydrazone is heated with an alcoholic solution of sodium ethoxide at 220—230°. Attempts to prepare it by converting coumarylphenylcarbinol by means of thionyl chloride into coumarylphenylmethyl chloride and reduction of the latter substance with zinc dust and acetic acid yielded a *compound*, $C_{30}H_{26}O_2$, m. p. 98°, probably 1 : 1′-dibenzyl-2 : 2′-dicoumarane. H. W.

Synthesis of 4-Ketochroman [Chromanone]. F. MAYER and L. VAN ZÜTPHEN (*Ber.*, 1924, **57**, [*B*], 200—202; cf. Arndt and Källner; Krollpfeiffer and Schultze, succeeding abstracts).—β-Chloropropionyl chloride is converted by phenol in the presence of carbon disulphide and aluminium chloride or phosphoryl chloride into a mixture of phenyl β-chloropropionate, b. p. 132—135°/12 mm., and a *substance*, $C_9H_{10}O_3$, m. p. 141—142°, which is regarded provisionally as *o*(?*p*)-hydroxyphenyl β-hydroxyethyl ketone. The ester is transformed by aluminium chloride into o-*hydroxyphenyl β-chloroethyl ketone*, colourless prisms, m. p. 70°, and p-*hydroxyphenyl β-chloroethyl ketone*, colourless, lustrous leaflets, m. p. 90° (m. p. 75—80°, directly after crystallisation from water), which are separated from one another by distillation with steam, with which only the ortho-derivative is volatile; the compound $C_9H_{10}O_3$ (above) is also formed in small amount. The ortho-compound is converted by aluminium chloride at 160—180° into 4-*ketochroman* [*chromanone*],  $C_6H_4{<}\begin{array}{l}CO\cdot CH_2\\ \quad\;\,|\\ O-CH_2\end{array}$, colourless, slender needles, m. p. 111°, b. p. 128°/13 mm. (the *sodium* salt, yellow crystals, the *oxime*, long, colourless needles, m. p. 144—145°, and the *benzylidene* derivative, m. p. 147—150°, are described). H. W.

Chromanone and Chromonol. F. Arndt and G. Källner (*Ber.*, 1924, 57, [*B*], 202—206; cf. Mayer and van Zütphen, preceding abstract; Krollpfeiffer and Schultze, succeeding abstract).—β-Phenoxypropionic acid is converted by concentrated sulphuric acid or, more advantageously from the point of view of yield, by successive treatment with phosphorus pentachloride and aluminium chloride in the presence of benzene, into *chromanone*, colourless plates, b. p. 127—128°/13 mm., m. p. 38° (Mayer and van Zütphen, *loc. cit.*, give m. p. 111°); 3-*benzylidenechromanone*, almost colourless crystals, has m. p. 113° (Mayer and van Zütphen give m. p. 147—150°). Chromanone condenses with *p*-nitrosodimethylaniline in alcoholic solution in the presence of potassium hydroxide and the product is reduced by hydrazobenzene to (?)3-p-*dimethylaminophenylaminochromanone*,  $C_6H_4{<}\begin{array}{l}CO\cdot CH\cdot NH\cdot C_6H_4\cdot NMe_2\\ \quad\;\,|\\ O-CH_2\end{array}$, golden-yellow leaflets, m. p. 154° (the colourless *hydrochloride* is described), which is oxidised by potassium ferricyanide to the corresponding, very unstable anil. The latter substance is converted by boiling, concentrated hydrochloric acid into *chromonol* (3-*hydroxy*-1 : 4-*benzopyrone*),  $C_6H_4{<}\begin{array}{l}CO\cdot C(OH)\\ \quad\;\,\|\\ O-CH\end{array}$, coarse, colourless needles, m. p. 181°; the *sodium*, *calcium*, and *magnesium* derivatives are described. The *benzoate* crystallises in colourless needles, m. p. 177·5°. 3-*Bromochromanone* has m. p. 69—70°. H. W.

Ring Closures from β-Phenoxypropionic Acids to Chromanones. F. Krollpfeiffer and H. Schultze (*Ber.*, 1924, 57, [*B*], 206—207; cf. Mayer and van Zütphen; Arndt and Källner, preceding abstracts).—The formation of chromanones from β-phenoxyphenylpropionic acids is most conveniently effected by heating mixtures of the latter and phosphoric anhydride under diminished pressure; the action of concentrated sulphuric acid or of phosphoric oxide in the presence of benzene is less suitable. *Chromanone* crystallises in colourless leaflets, m. p. 39—40°, b. p.

124°/14 mm.; the *semicarbazone*, small, colourless needles, has m. p. 227°. β-p-*Toloxypropionic acid*, colourless needles, m. p. 147—148°, yields 6-methylchromanone, m. p. 34—36° (cf. von Auwers and Krollpfeiffer, A., 1915, i, 442). H. W.

Syntheses of Chromones and Coumarins. G. WITTIG (*Ber.*, 1924, **57**, [*B*], 88—95).—Chromones are readily obtained by condensation of *o*-acetylphenols with sodium and ethyl acetate, followed by ring closure of the diketones thus produced.

The displacement of the acetyl group into the ortho position to the hydroxy radical is effected by heating the phenolic esters with aluminium chloride at 110—115°; 4-chloro-6-acetylphenol (3-chloro-6-hydroxyphenyl methyl ketone), m. p. 53·5—54·7°, 4-*chloro*-6-*acetyl*-m-*cresol*, colourless needles, m. p. 69—70°, and 6-acetyl-*p*-cresol, m. p. 45—46°, are described.

4-Chloro-6-acetylphenol is converted by acetic anhydride and sodium acetate at 160—170° into a mixture of 6-chloro-4-methylcoumarin, m. p. 186—187°, and 6-*chloro*-2-*methylchromone*,

$C_6H_3Cl<\begin{matrix}CO\cdot CH\\ \quad\;\; \| \\ O—CMe\end{matrix}$, colourless needles, m. p. 115—116°. The substances are separated from one another by means of an alcoholic solution of sodium ethoxide, which causes fission of both rings with the production of 5-*chloro*-β-*methylcoumaric acid*, m. p. 156° (decomp.), and 4-chloro-6-acetylacetophenol. Addition of acid converts the former into its lactone, whereas the latter can be removed by aqueous sodium hydroxide and subsequently reconverted into its cyclic compound by sulphuric acid. The mixture of chromone and coumarone is converted by boiling 2*N*-sodium hydroxide solution into 5-chlorosalicylic acid, m. p. 173—174°, which owes its formation to fission of the intermediately formed diketone, $OH\cdot C_6H_3Cl\cdot CO\cdot CH_2\cdot COMe$.

A similar series of reactions has been applied to 4-chloro-6-acetyl-*m*-cresol, whereby the following compounds are produced: 6-*chloro*-4 : 7-*dimethylcoumarin*, needles, m. p. 206—207°; 4-*chloro*-6-*acetylaceto*-m-*cresol*, pale yellow, lustrous leaflets, m. p. 115·5—116·5°; 6-*chloro*-2 : 7-*dimethylchromone*, needles, m. p. 144·5—145·5°; 5-chloro-4-methylsalicylic acid, m. p. 203—204°. Similarly, 6-acetyl-*p*-cresol gives 2 : 6-dimethylchromone, m. p. 99·5—100°, 4 : 6-dimethylcoumarin, m. p. 147·5—148°, and 5-methylsalicylic acid, m. p. 148·5—149°.

p-Chlorophenyl methyl ether is converted by acetyl chloride and aluminium chloride in the presence of carbon disulphide into 4-*chloro*-6-*acetylphenyl methyl ether*, needles, m. p. 29—30°, which is transformed by sodium and ethyl acetate into 4-*chloro*-6-*acetylacetophenyl methyl ether*, yellow prisms, m. p. 76·5—77·5°; the latter compound is converted by concentrated hydriodic acid or, less advantageously, by hydrobromic and glacial acetic acids into 6-chloro-2-methylchromone.

The preparation of 6-chloro-2-methylchromone, 6-chloro-2 : 7-dimethylchromone, and 2 : 6-dimethylchromone by the action of sodium and ethyl acetate on the requisite phenol is described.

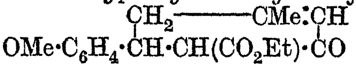
4-*Chloro*-6-*acetylacetophenol* crystallises in pale yellow leaflets, m. p. 110—111°; 6-*acetylaceto*-p-*cresol* has m. p. 94·5—96°.

H. W.

Interaction of Ethyl Acetoacetate with o-Hydroxystyryl Ketones. T. A. Forster and I. M. Heilbron (*J. Chem. Soc.*, 1924, **125**, 340—347).—2-Hydroxystyryl methyl ketone condenses with ethyl acetoacetate, in presence of sodium ethoxide or aqueous sodium hydroxide, to give 4-*acetonyl*-2-*methyl*-γ-*pyran*,

$$C_6H_4<\begin{matrix}CH(CH_2Ac)\cdot CH\\ O\text{————}CMe\end{matrix},$$

colourless needles, m. p. 134—135° (*phenylhydrazone*, colourless needles, m. p. 200°). Condensation of 2-hydroxystyryl phenyl ketone with ethyl benzoylacetate similarly affords 2-*phenyl*-4-*phenacyl*-γ-*pyran*, colourless crystals, m. p. 130°, together with 2-*phenyl*-4-*phenacyl*-γ-*pyran*-3-*carboxylic acid*, colourless prisms, m. p. 157°. Condensation of 2-methoxystyryl methyl ketone with ethyl acetoacetate affords *ethyl* 3-o-*methoxyphenyl*-5-*methyl*-Δ⁵-cyclo*hexen*-1-*one*-2(or 4)-*carboxylate*,



$$\begin{matrix}CH_2\text{———}CMe{:}CH\\ OMe\cdot C_6H_4\cdot CH\cdot CH(CO_2Et)\cdot CO\end{matrix}$$

or

$$\begin{matrix}CH(CO_2Et)\cdot CMe{:}CH\\ OMe\cdot C_6H_4\cdot CH\text{——}CH_2\text{——}CO\end{matrix},$$

pale yellow needles, m. p. 139°.

2-*Methoxystyryl phenyl ketone* (colourless needles, m. p. 60°) condenses with ethyl acetoacetate to give *ethyl* 5-*phenyl*-3-o-*methoxyphenyl*-Δ⁵-cyclo*hexen*-1-*one*-2-*carboxylate*, colourless prisms, m. p. 95°, whilst 2-hydroxystyryl phenyl ketone under similar conditions affords 3-*acetyl*-4-*phenacyldihydrocoumarin*,

$$C_6H_4<\begin{matrix}CH(CH_2Bz)\cdot CHAc\\ O\text{————}CO\end{matrix},$$

colourless needles, m. p. 175°, together with a small quantity of a colourless crystalline *substance*, m. p. 214°.

6-, 7-, and 8-*Methoxy*-4-*acetonyl*-2-*methyl*-γ-*pyran* respectively form feathery needles, m. p. 119°, colourless crystals, m. p. 149°, and colourless needles, m. p. 168°, the 8-compound affording a colourless, crystalline *phenylhydrazone*, m. p. 186°.

Spectrographic measurements support certain of the above constitutional formulæ.

F. G. W.

The Brazilin and Hæmatoxylin Question. III. The Degradation Product of Brazilin obtained by Schall and Dralle. P. Pfeiffer and J. Oberlin (*Ber.*, 1924, **57**, [*B*], 208—213; cf. A., 1917, i, 661; 1920, i, 561).—The compound, $C_9H_6O_4$, isolated by Schall and Dralle (A., 1892, 502) by the action of atmospheric oxygen on an alkaline solution of brazilin has been considered by Feuerstein and von Kostanecki (A., 1899, i, 538) to be 3 : 7-dihydroxychromone,

$$HO\cdot C_6H_3<\begin{matrix}O\text{—}CH\\ CO\cdot C\cdot OH\end{matrix}.$$

This is confirmed by the observation that synthetic 3 : 7-dimethoxychromone is identical with the dimethyl ether of the degradation product.

β-3-*Methoxyphenoxypropionic acid*, $OMe\cdot C_6H_4\cdot O\cdot CH_2\cdot CH_2\cdot CO_2H$, colourless, lustrous crystals, m. p. 81—83°, is prepared in poor yield (17%) from resorcinol methyl ether and β-iodopropionic acid. It is converted by treatment with zinc chloride at 145°, with phosphoric anhydride at about 100°, or by the successive action of phosphorus pentachloride and aluminium chloride, into 7-methoxychromanone, identical with the product obtained by Pfeiffer and Grimmer by the reduction of 7-methoxychromone (cf. A., 1917, i, 661). The chromanone is transformed by amyl nitrite and potassium amoxide in amyl alcoholic solution into 3-*oximino-7-methoxychromanone* (3-*oximino*-7-*methoxy*-2 : 3-*dihydro*-1 : 4-*benzopyrone*), almost colourless, microscopic leaflets, m. p. 146—147° (decomp.), which, when treated with glacial acetic and dilute sulphuric acids, gives 3-*hydroxy*-7-*methoxychromone* (3-*hydroxy*-7-*methoxy*-1 : 4-*benzopyrone*), colourless, microscopic needles, m. p. 171—172°. 3 : 7-*Dimethoxychromone*, prepared from the preceding compound and methyl sulphate, forms colourless crystals, m. p. 169—170°. H. W.

Linear and Angular Diphthaloylthianthrens. K. Brass and K. Heide (*Ber.*, 1924, **57**, [*B*], 104—121).—An extension of the work on compounds containing the dithiin ring to anthracene derivatives. In these, the stability of the ring is much greater than in the corresponding naphthalene compounds (cf. Brass and Köhler, A., 1922, i, 1050), and its conversion by loss of an atom of sulphur into the thiophen ring is effected only under drastic conditions. Contrary to the views of Scholl and Seer (A., 1911, i, 557), both linear and angular diphthaloylthianthrens are well-defined vat dyes.

2 : 3 : 6 : 7-Diphthaloylthianthren,

$$C_6H_4{<}\genfrac{}{}{0pt}{}{CO}{CO}{>}C_6H_2{<}\genfrac{}{}{0pt}{}{S}{S}{>}C_6H_2{<}\genfrac{}{}{0pt}{}{CO}{CO}{>}C_6H_4$$

(cf. Scholl and Seer, *loc. cit.*), is prepared by heating a mixture of molecular proportions of 2 : 3-dibromoanthraquinone and crystalline sodium sulphide gradually to 210° under pressure; it crystallises in small, brown needles which do not melt below 360°. It is remarkably stable towards nitric acid. It is reduced by alkaline sodium hyposulphite or by zinc dust and alkali hydroxide to *tetrahydroxydinaphthathianthren*, pale greenish-yellow needles; the *tetrabenzoate*, golden-yellow needles, which darken at 320° but do not melt below 350°, is hydrolysed and oxidised by concentrated sulphuric acid to benzoic acid and diphthaloylthianthren.

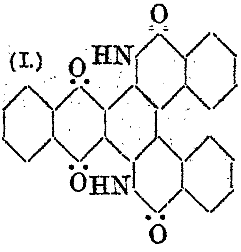
2 : 3-Dibromoquinizarin is transformed by boiling acetic anhydride in the presence of fused zinc chloride into the corresponding *diacetate*, pale yellow needles, m. p. 242° (indefinite), and by benzoyl chloride in the presence of nitrobenzene into the *dibenzoate*, yellow needles. It is converted by an equimolecular proportion of crystalline sodium sulphide at a temperature not exceeding 190° into 1 : 4 : 5 : 8-*tetrahydroxy*-2 : 3 : 6 : 7-*diphthaloylthianthren*, dark green needles with a metallic lustre which do not melt below 360°; the dithiin is more advantageously prepared by the action of sodium sulphide on an aqueous suspension of 2 : 3-dibromo-1 : 4 : 9 : 10-anthra-

diquinone (cf. Dimroth, Friedmann, and Kämmerer, A., 1920, i, 444) in the absence of air. When heated with nitric acid (*d* 1·52) on the steam-bath it loses almost exactly a molecular proportion of sulphur and is doubtless transformed into diquinizarinthiophen, which, however, has not been more closely investigated. The dithiin yields a *monosodium* salt, $C_{28}H_{11}O_8S_2Na$, a *di-sodium* salt, and a *di-potassium* salt; greater proportions of base could not be introduced into the molecule. It is converted by alkaline hyposulphite solution or by zinc dust and alkali hydroxide into a blood-red vat from which *octahydroxydianthracenedithiin* separates in brown flocks after addition of acid; it has m. p. 238—244°. The corresponding *octabenzoate* crystallises in pale yellow needles, m. p. 240—244°. Tetrahydroxydiphthaloylthianthren is converted by benzoyl chloride in the presence of boiling nitrobenzene into the corresponding *tetrabenzoate*, a greenish-yellow, crystalline powder which does not melt below 360°, and by acetic anhydride in the presence of dehydrating agents into the *diacetate*, brown leaflets.

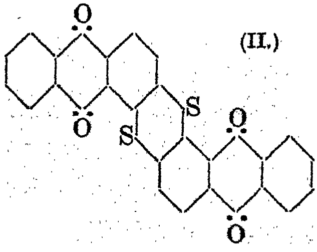
2 : 3-Dichloro-1 : 4-diaminoanthraquinone is converted by crystalline sodium sulphide at 210° into 1 : 4 : 5 : 8-*tetra-amino*-2 : 3 : 6 : 7-*diphthaloylthianthren*, $C_{28}H_{16}O_4N_4S_2$, small, dark blue needles which do not melt below 360°; with alkaline sodium hyposulphite solution it yields a red vat from which ammonia is evolved at 50—60°. Benzoylation of the vat leads to the production of the expected *octabenzoyl* derivative, $C_{84}H_{52}O_{12}S_2$, long, pale yellow, prismatic needles, m. p. 302° (decomp.). 1 : 4 : 5 : 8-*Tetrabenzoylamino*-2 : 3 : 6 : 7-*diphthaloylthianthren* crystallises in small, greenish-yellow, lustrous needles, which do not melt below 360°.

The presence of two benzoylamino groups in the vicinal position to the halogen atoms of 2 : 3-dichloro-1 : 4-dibenzoylaminoanthraquinone appears to inhibit the formation of the dithiin ring, since the substance is converted by sodium sulphide at 180° into the phenanthridone (I), microscopic, green needles which do not melt below 300°.

(I.)



(II.)



3 : 4 : 7 : 8-*Diphthaloylthianthren* [*thioindanthren*] (II), dark green, coppery needles, which do not melt below 360°, is prepared from 1 : 2-dibromoanthraquinone and sodium sulphide at 190°. With alkaline sodium hyposulphite solution, it gives a blood-red vat from which the expected *tetrabenzoate*, yellow needles, is obtained by the action of benzoyl chloride. H. W.

Hydroxypyrrole Derivatives [IV] and certain Reactions of Chloroacetyldiacetonitriles. E. BENARY and G. SCHWOCH (*Ber.*, 1924, **57**, [*B*], 332—339; cf. Benary and Lau, A., 1923, i, 366).—The remarkable formation of dyes when treated with alcoholic or liquid ammonia appears to be a general property of halogenoacyl derivatives of dinitriles containing an aromatic substituent and an unsubstituted imino group; when the latter contains a substituent, the normal formation of hydroxypyrroles is observed.

Chloroacetyldiacetonitrile, $NH_2{\cdot}CMe{:}C(CN){\cdot}CO{\cdot}CH_2Cl$, is converted by methyl-alcoholic ammonia into 4-*hydroxy*-2-*methylpyrrole*-3-*nitrile*,  $HN<\begin{matrix}CMe{:}C{\cdot}CN\\ CH{=}C{\cdot}OH\end{matrix}$, which is too unstable to permit its isolation in the homogeneous condition; it is characterised by its conversion into 5-*benzeneazo*-4-*keto*-2-*methylpyrroline*-3-*nitrile*, orange needles, decomp. 240°, by benzenediazonium solution, and by formaldehyde into *methylenebis*-4-*keto*-2-*methylpyrroline*-3-*nitrile*, an orange precipitate, decomp. about 250°.

C-*Chloroacetyl*-p-*toluacetodinitrile*,

$NH_2{\cdot}C(C_6H_4Me){:}C(CN){\cdot}CO{\cdot}CH_2Cl$,

matted needles, m. p. 166—168°, is prepared from *p*-toluacetodinitrile and chloroacetyl chloride in the presence of pyridine; it is converted by methyl-alcoholic ammonia into the *dye*,  $\begin{matrix}C(CN)\text{——}CO\\ C(C_6H_4Me){\cdot}NH\end{matrix}>C{:}C<\begin{matrix}C(CN){:}C{\cdot}C_6H_4Me\\ CH_2\text{—}NH\end{matrix}$, H_2O, a dark, violet-red powder, decomp. about 200°. The chloro compound is transformed by potassium hydrogen sulphide in alcoholic solution into the corresponding *sulphide*, $[NH_2{\cdot}C(C_6H_4Me){:}C(CN){\cdot}CO{\cdot}CH_2]_2S$, colourless prisms, decomp. 218·5—220°.

p-*Methoxybenzoacetodinitrile*, coarse, colourless prisms, m. p. 118°, is prepared by the action of sodium wire on anisonitrile and acetonitrile dissolved in hot benzene. It is converted by treatment in warm alcoholic solution with dilute hydrochloric acid into p-*methoxyphenyl cyanomethyl ketone*, $C_6H_4(OMe){\cdot}CO{\cdot}CH_2{\cdot}CN$, prisms, m. p. 130·5°; this ketone, with phenylhydrazine and glacial acetic acid in cold alcoholic solution, affords the *phenylhydrazone*, soft needles, m. p. 135—136°, which when heated above its m. p. or boiled with dilute acetic acid passes into 5-*imino*-1-*phenyl*-3-p-*methoxyphenylpyrazolone*,  $PhN<\begin{matrix}N\text{===}C{\cdot}C_6H_4{\cdot}OMe\\ C({:}NH){\cdot}CH_2\end{matrix}$, lustrous leaflets, m. p. 188°. The dinitrile is converted by hydroxylamine hydrochloride in boiling, aqueous-alcoholic solution into 5-*imino*-3-p-*methoxyphenyl*iso*oxazolone*, prisms, m. p. 136—137°. C-*Chloroacetyl*-p-*anisylacetodinitrile*, $C_{12}H_{11}O_2N_2Cl$, needles, m. p. 164°, is converted by methyl-alcoholic ammonia into the dark, violet-red *dye*, $C_{24}H_{18}O_3N_4$ (cf. formula above), decomp. 200° after darkening at 185°, and by potassium hydrogen sulphide into the *sulphide*, $[OMe{\cdot}C_6H_4{\cdot}C(NH_2){:}C(CN){\cdot}CO{\cdot}CH_2]_2S$, a crystalline powder, m. p. 196—197° (decomp.) after darkening and softening at 190°.

C-*Chloroacetyl*-N-p-*anisyldiacetonitrile*, $C_{13}H_{13}O_2N_2Cl$, lustrous needles, m. p. 80—81·5°, is converted by alcoholic potassium hydroxide solution into 3-*hydroxy*-1-p-*anisyl*-5-*methylpyrrole*-4-*nitrile*, matted needles, m. p. 190—192° (decomp.).

N-*Phenyl*-α-*anilinoacetylbenzoacetodinitrile*, prepared from chloroacetylbenzoacetodinitrile and aniline, decomposes at 258—260° when rapidly heated; with mercuric chloride and dilute hydrochloric acid it yields the additive *compound*, $C_{23}H_{19}ON_3,HCl,HgCl_2$, pale yellow needles, m. p. 172°. When boiled with an excess of glacial acetic acid the base yields α-*acetanilidoacetyl*-β-*anilino*-β-*phenylacrylamide*, $NHPh{\cdot}CPh{:}C(CO{\cdot}CH_2{\cdot}NAcPh){\cdot}CO{\cdot}NH_2$, colourless prisms, decomp. 296—298°, which is also obtained from chloroacetylbenzoacetodinitrile, aniline, and glacial acetic acid at 115—120°.

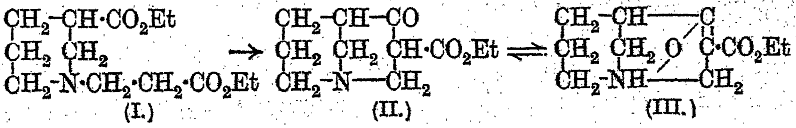
C-*Anilinoacetyl*-N-*phenyldiacetonitrile*,

$$NHPh{\cdot}CMe{:}C(CN){\cdot}CO{\cdot}CH_2{\cdot}NHPh,$$

small needles, m. p. 214—216° when rapidly heated, is obtained from chloroacetyldiacetonitrile and aniline or from the latter and *C*-chloroacetyl-*N*-phenylbenzoacetodinitrile; it gives a lemon-yellow *picrate*, m. p. 165—166° after previous softening, and the additive *compound*, $C_{18}H_{17}ON_3,HCl,HgCl_2$, colourless needles, decomp. 230° after darkening at 215°.

The action of phenylhydrazine on chloroacetyldiacetonitrile leads somewhat unexpectedly to the production of 5-*chloromethyl*-1-*phenyl*-3-*methylpyrazole*-4-*nitrile*,  $\mathrm{PhN}<\begin{matrix}\mathrm{N{=\!=\!=}CMe}\\ \mathrm{C(CH_2Cl){:}C{\cdot}CN}\end{matrix}$, needles, m. p. 130·5° after softening, which is also obtained from cyanoacetone phenylhydrazone and chloroacetyl chloride. It is hydrolysed to 5-hydroxymethyl-1-phenyl-3-methylpyrazole-4-carboxylic acid (cf. Benary, A., 1910, i, 434). Treatment with alcoholic potassium hydroxide solution transforms it into 5-*ethoxymethyl*-1-*phenyl*-3-*methylpyrazole*-4-*nitrile*, slender needles, m. p. 68·5°, which is unaffected by boiling, concentrated hydrochloric acid. The chloride is converted by methyl-alcoholic ammonia at 50—60° into 5-*aminomethyl*-1-*phenyl*-3-*methylpyrazole*-4-*nitrile*, long, colourless needles, m. p. 58—59° (*picrate*, pale yellow leaflets, m. p. about 250—251° [decomp.]) from which 5-*hydroxymethyl*-1-*phenyl*-3-*methylpyrazole*-4-*nitrile*, needles, m. p. 114—116°, is obtained by means of nitrous acid. H. W.

Synthesis of a New Bicyclic Nitrogen Ring. *iso*Granatanine Derivatives. Preparation of an Isomeride of Homococaine. S. M. McElvain and R. Adams (*J. Amer. Chem. Soc.*, 1923, **45**, 2738—2750).—Ethyl nipecotinate (piperidine-3-carboxylate) on condensation with ethyl β-chloropropionate in alcoholic solution in the presence of silver oxide yields ethyl (3-carbethoxypiperidino)-propionate (I), this being converted by sodium in xylene solution into ethyl *iso*granatonine carboxylate (II).



(I.) (II.) (III.)

Reduction of the ketone converts it into ethyl granatolinecarboxylate, and benzoylation of the latter yields a compound isomeric with homococaine. It is a less efficient local anæsthetic than cocaine, and is considerably more toxic than the latter.

Nicotinic acid nitrate was obtained by adding nicotine to nitric acid (*d* 1·42) and heating at 100° for several hours. The nitrate was converted into the hydrochloride by heating with hydrochloric acid, removing excess of the latter in a vacuum, dissolving the product in water, and precipitating with alcohol. Pure nicotinic acid was then obtained in the usual manner. Ethyl nicotinate was obtained by treating nicotinic acid (or its hydrochloride) successively with thionyl chloride and alcohol (excess of chloride being removed intermediately). Nipecotinic acid was prepared by the reduction of nicotinic acid hydrochloride with hydrogen in the presence of platinum oxide catalyst (cf. Freudenberg, A., 1919, i, 93). *Ethyl nipecotinate* is a colourless, water-soluble liquid, b. p. 102—104°/7 mm., d_{20}^{20} 1·0121, n_D^{19} 1·4592 (*hydrochloride*, needles, m. p. 110—111°); it may also be obtained (less satisfactorily) by the catalytic reduction of ethyl nicotinate hydrochloride in alcoholic solution, and by the reduction of ethyl nicotinate in alcoholic acetic acid. *Ethyl* (3-*carbethoxypiperidino*)*acetate*, obtained from ethyl nipecotinate and ethyl chloroacetate in presence of finely powdered silver oxide, has b. p. 147—149°/5 mm., d_{20}^{20} 1·0684, n_D^{18} 1·4607. The free *acid*, obtained by hydrolysis of the ester or by condensing nipecotinic acid with chloroacetic acid in the presence of hydrochloric acid, forms white crystals, m. p. 268—270° (decomp.). *Ethyl* (3-*carbethoxypiperidino*)*propionate*, obtained similarly from ethyl nipecotinate and ethyl-β-chloropropionate or from nipecotinic acid and β-chloropropionic acid, has b. p. 159—161°/5 mm., d_{20}^{20} 1·0452, n_D^{18} 1·4605. *Ethyl* iso*granatoninecarboxylate hydrochloride* forms white, microscopic crystals, m. p. 187—189°; it is extremely soluble in water and gives a deep reddish-purple coloration with ferric chloride. The keto-ester hydrochloride can be obtained crystalline by adding dry ether to its alcoholic solution until a faint cloudiness appears and then cooling to about −12°. *Ethyl* iso*granatoninecarboxylate* is a thick, colourless oil, b. p. 137—139°/8 mm., d_{20}^{20} 1·1381, n_D^{18} 1·5070; it gives a pronounced colour with acidified ferric chloride solutions. *Ethyl* iso*granatolinecarboxylate hydrochloride*, obtained by the reduction of the ketone with sodium amalgam in acid solution or by catalytic reduction in alcoholic solution in the presence of the platinum oxide catalyst, melts at 199—201°. An *isomeride* appears to be present in the mother-liquors left after crystallisation. The *benzoyl* derivative of the alcohol is obtained in the form of its hydrochloride as a white, crystalline powder.

An ethereal solution of the crude keto-ester (II) gradually deposits crystals which from their solubility in organic solvents probably consist of compound (III). F. G. P.

Pepper-substances. III. The Chavicine of Black Pepper. II. E. Ott and O. Lüdemann (*Ber.*, 1924, **57**, [*B*], 214—216).—Chavicine is purified by dissolution in benzene, addition of stannic bromide, and precipitation of the additive compound (as a resinous mass) by means of ether. Analysis of the chavicine, regenerated after further dissolution in benzene and precipitation with ether, confirms the previous conclusion (Ott and Eichler, A., 1922, i, 1026) that it is stereoisomeric with piperine. Treatment of purified chavicine with alcoholic alkali hydroxide solutions yields unchanged material, *iso*chavicic acid, and piperidine; wax alcohols and fatty acids are not produced as is the case when crude chavicine is employed. H. W.

Ester Condensations with Ethyl *o*-Aminophenylacetate and Oxindole. W. Wislicenus and H. Bubeck (*Annalen*, 1924, **436**, 113—124).—It was expected that by condensing ethyl *o*-aminophenylacetate (Neber, A., 1922, i, 545) with ethyl formate, indole-3-carboxylic acid would be formed, but actually the product was oxindole-3-aldehyde (Friedländer, A., 1910, i, 592). Ethyl oxalate with the amino ester gave ethyl 2 : 3-dihydroxycinchoninate,

$$C_6H_4<\begin{matrix}C(CO_2Et){:}C{\cdot}OH\\ NH\text{———}CO\end{matrix},$$

together with a little oxindole-3-glyoxylic ester. Oxindole-3-aldehyde, obtained as above or from oxindole itself, forms yellow needles, m. p. 205—206°, and its anil has m. p. 254°. *Oxindole-3-glyoxylic acid,* the ester of which was obtained by condensing oxindole and ethyl oxalate, forms orange-yellow leaflets, m. p. 262—265° (decomp.); *anilide*, yellow leaflets, m. p. 261° (decomp.). The *ethyl* ester crystallises in orange needles, m. p. 187—188°, gives a green, crystalline *copper* salt, a *benzoyl* derivative (yellow needles, m. p. 160—161°), an *anil* (yellow prisms, m. p. 191—193°), and the corresponding *compound* with α-naphthylamine (m. p. 190°). Titration with bromine indicates that ethyl oxindole-3-glyoxylate exists solely in the *enolic* form. When treated with phenylhydrazine, it gives a mixture of the *phenylhydrazide* of the acid (needles, m. p. 238—239°) and the *phenylhydrazone* of the ester (yellow prisms, m. p. 160—164°), but at higher temperatures a *substance,* $C_{16}H_{11}O_2N_3$, crystallising in colourless needles, which decomposes at 265°. The *phenylmethylhydrazone* of the ethyl ester forms yellowish-brown prisms, m. p. 139°. *Methyl oxindole-3-glyoxylate* forms yellow needles, m. p. 167—169° (decomp.), and gives a *phenylhydrazone,* m. p. 197° (decomp.), which again gives the above compound, $C_{16}H_{11}O_2N_3$, when boiled with glacial acetic acid.

Ethyl 2 : 3-*dihydroxycinchoninate* forms needles, sintering about 210°, melting at 227—228°, and decomposing at 230°. It is a weak acid, giving crystalline ammonium and hydrazine salts. The *acid* forms white needles and decomposes without melting at 180°, giving 2 : 3-dihydroxyquinoline (Madelung, A., 1913, i, 92). Its *anilide* forms needles, m. p. 260° (decomp.). The *benzoyl* and *acetyl* derivatives of the ester (only the 3-hydroxy group reacted in each case) melt at 182—183° and 190°, respectively. W. A. S.

[Tri-indolylmethanes and Aldehydes, Ketones, Ketonic Esters, and Keto-nitriles of Substituted Indoles.] H. FISCHER (*Ber.*, 1924, 57, [*B*], 356).—2-Methylindole-3-aldehyde (cf. Fischer and Pisbor, this vol., i, 86) has been obtained previously by Barger (A., 1917, i, 476). H. W.

Mechanism of Diazo Coupling Reactions. IV. Azo Dyes from 2-Methylenetrialkylindolines. W. KÖNIG and J. MÜLLER (*Ber.*, 1924, 57, [*B*], 144—149; cf. A., 1923, i, 862).—2-Methylene-1 : 3 : 3-trialkylindolines couple with diazonium salts to yield azo dyes whereby the alkyl group in position 1 is removed as the corresponding alcohol. The new compounds are of the general type,

$\begin{array}{l} C(Alk)_2{\cdot}C{:}CH{\cdot}N{:}NAr \\ C_6H_4\text{—}NH \end{array}$

, which becomes somewhat modified when a chromophoric group is present in the para-position in the diazonium component. The facility with which coupling occurs depends on the nature of the 3-alkyl groups.

The following compounds are described: 1 : 2 : 3 : 3-*Tetramethylindoleninium bromide*, pale yellow crystals, m. p. 252° (decomp.), and the corresponding *perchlorate*, long, colourless needles, m. p. 192° (decomp.). 2-Methyl-1 : 3 : 3-triethylindoleninium *picrate*, yellow needles, m. p. 180°, and the very hygroscopic *chloride*, slender, colourless needles, m. p. 131°. 1 : 2-*Dimethyl*-3 : 3-*diethylindoleninium picrate*, dark yellow needles, m. p. 167° (the corresponding *chloride* and *perchlorate* are extremely hygroscopic). 2 : 3 : 3-*Trimethyl*-1-*ethylindoleninium perchlorate*, needles, m. p. 197° (decomp.).

2-Benzeneazomethylene-3 : 3-dimethylindoline is isolated as the *hydrochloride*, $C_{17}H_{18}N_3Cl$, m. p. 186° (decomp.), by treatment of a solution of 1 : 2 : 3 : 3-tetramethylindolinium iodide (or bromide) with sodium hydroxide and addition of benzenediazonium chloride to the emulsion of the methylene base. 2-p-*Nitrobenzeneazomethylene*-3 : 3-*dimethylindoline*, prepared in a similar manner from 2-methylene-1 : 3 : 3-trimethylindoline or 2-methylene-1-ethyl-3 : 3-dimethylindoline, crystallises in reddish-brown leaflets, m. p. 168°; the corresponding *hydrochloride*, brownish-red needles, decomp. about 286°, the *hydrobromide*, brownish-red needles, decomp. 250°, and the *acetate*, leaflets, are described. 2 : 4′-*Nitro*-2′-*methoxybenzeneazomethylene*-3 : 3-*dimethylindoline* forms lustrous, steel-blue needles, m. p. 211° (*hydrochloride* [$+CH_3{\cdot}CO_2H$], m. p. 128°, and subsequently decomp. about 290°). 2-*p*-Nitrobenzeneazomethylene-3 : 3-diethylindoline could not be caused to crystallise; the *hydrochloride*, brownish-yellow needles, has m. p. 280° (decomp.). 2-p-*Acetylbenzeneazomethylene*-3 : 3-*dimethylindoline* crystallises in lustrous, red needles, m. p. 191°; the *hydrobromide* forms reddish-brown needles, m. p. 264°. H. W.

Supposed Syntheses from Ethyl Isatin-1-carboxylate. A. HANTZSCH (*Ber.*, 1924, 57, [*B*], 195—199).—A criticism of the work of Heller (A., 1918, i, 309). Heller's 2 : 3-dihydroxy-2 : 3-dihydroindole-2-carboxylic acid is shown to be formylisatoic acid, $CHO{\cdot}NH{\cdot}C_6H_4{\cdot}CO{\cdot}CO_2H$, since its production from ethyl isatin-

1-carboxylate by the action of warm water or cold sulphuric acid (50%) is accompanied by that of acetaldehyde whilst, also, it is hydrolysed in alkaline solution to isatoic and formic acids; this conclusion is confirmed by the analysis of the ethyl ester, m. p. 67°. The supposed "lactone-like anhydride," m. p. 108°, is proved to be 1-formylisatin, since its optical properties are almost identical with those of 1-acetylisatin; attempts to prepare it directly from isatin and formic acid in the presence of dehydrating agents were, however, unsuccessful. Heller's 2 : 4-dihydroxy-1 : 2 : 3 : 4-tetrahydroquinoline-2-carboxylic acid is, in reality, formylanthranilic acid, which is transformed by acetic anhydride and sodium acetate into acetylanthranilic acid (Heller's hydroxydihydroquinoline-2-carboxylic acid, m. p. 184°). The observed formation of yellow solutions of the colourless formylisatoic acid in water and anhydrous solvents is due to the ready production of 1-formylisatin. H. W.

Catalytic Hydrogenation of Pyridine. N. Zelinsky and P. Borisoff (*Ber.*, 1924, **57**, [*B*], 150—153).—Pyridine is very readily hydrogenated to piperidine in the presence of platinised asbestos (40%) at 150°. The catalyst does not become poisoned, since it retains its ability to cause the hydrogenation of benzene. At about 250°, it smoothly effects the dehydrogenation of piperidine, but, after use, it is no longer capable of bringing about the reduction of benzene or pyridine or the dehydrogenation of *cyclo*hexane. Palladised asbestos is a still more effective agent for the hydrogenation of pyridine at 150°; after use, however, it is found to have lost all activity towards benzene. It readily causes the dehydrogenation of piperidine, but not of *cyclo*hexane at 250°; after use, it is incapable of effecting hydrogenation.

The preparation of the highly active catalyst is effected in the following manner. Asbestos, which has been washed with acid and ignited, is soaked in a concentrated, faintly acid solution of platinum or palladium chloride at the temperature of boiling water and subsequently immersed in cold formaldehyde solution (35—40%). It is then treated with concentrated sodium hydroxide solution (40—50%), initially at 0° and finally on the water-bath. The product is washed thoroughly with water, immersed in dilute acetic acid solution, and again washed until the filtrate is neutral in reaction. It is dried for a short period at 110°. H. W.

Complex [Pyridine, Pyrazine, and Quinoxaline] Salts of Bivalent Iron. H. Ley, C. Schwarte, and O. Münnich.—(See ii, 228.)

The Product of the Action of Acidic Reducing Agents on Indigotin. W. Madelung and P. Siegert (*Ber.*, 1924, **57**, [*B*], 222—233).—The reduction of indigotin in the presence of acids leads to the opening of the ring with formation of 2 : 2′-diamino-ω-styrylacetophenone.

The gradual addition of indigotin and finely-divided iron to an almost saturated solution of hydrogen chloride in alcohol leads to the separation of *2 : 2′-diamino-ω-styrylacetophenone hydrochloride*, $NH_2 \cdot C_6H_4 \cdot CO \cdot CH_2 \cdot CH\colon CH \cdot C_6H_4 \cdot NH_2,HCl$, pale brown crystals; the corresponding *picrate, sulphate,* and perchlorate are described. The hydrochloride is converted by acetic anhydride in the presence of pyridine into the *acetyl* derivative, $C_{20}H_{20}O_3N_2$, colourless leaflets, m. p. 181° (the *perchlorate* is described). With formaldehyde and benzaldehyde, respectively, the base gives the *compounds,* $C_{17}H_{16}ON_2$, greenish-yellow crystals, and $C_{23}H_{20}ON_2$, slender, greenish-yellow crystals. The conversion of indigotin into 2 : 2′-diamino-ω-styrylacetophenone can be effected by ferrous chloride or by the addition of indigo-white to alcoholic hydrogen chloride, whereby disproportionation occurs accompanied by precipitation of indigotin.

2 : 2′-Diamino-ω-styrylacetophenone is very easily dehydrogenated. The hydrochloride is converted by solution in warm pyridine and exposure to air into 2-o-*aminostyrylindoxyl,*

$C_6H_4<\begin{matrix}C(OH)\\NH\end{matrix}>C\cdot CH{:}CH\cdot C_6H_4\cdot NH_2$, small needles, m. p. 161°, which is readily oxidised further; it gives a *monoacetyl* derivative, decomp. above 250°. Deoxyindigotin,

$$C_6H_4<\begin{matrix}CO\\NH\end{matrix}>C{:}C<\begin{matrix}CH_2\\NH\end{matrix}>C_6H_4$$

(cf. Borsche and Meyer, A., 1922, i, 55), is also obtained by the action of air on solutions of 2 : 2′-diamino-ω-styrylacetophenone in pyridine and is the sole product of the action of alcoholic solutions of potassium hydroxide or sodium alkoxide on the base. The ultimate product of the dehydrogenation of 2 : 2′-diamino-ω-styrylacetophenone is the *substance,*

$C_6H_4<\begin{matrix}CO\\-N\end{matrix}\geqslant C\cdot C\leqslant\begin{matrix}CH\\NH\end{matrix}>C_6H_4$, cocoa-brown, rhombic leaflets (*monoacetyl* derivative, pale yellow leaflets, decomp. 245—250°). When its solution in pyridine is exposed to air for 3—4 days the dimeric *compound,* $(C_{16}H_{10}ON_2)_2$, separates in the form of dark violet-blue, slender needles. A second dimeric *compound,* $(C_{16}H_{10}ON_2)_2$, is obtained by the action of concentrated acids on a solution of the monomeric substance, $C_{16}H_{10}ON_2$; the latter, which forms orange crystals, is immediately coloured green, probably owing to the formation of an unstable salt, and subsequently rapidly passes into the tile-red salt of the dimeride, which can also be obtained by dehydrogenation or disproportionation from the compounds $C_{16}H_{16}ON_2$, $C_{16}H_{14}ON_2$, and $C_{16}H_{12}ON_2$. It has well-marked basic properties and gives sparingly soluble salts with mineral acids, the most characteristic of which is the *hydriodide,* $C_{32}H_{20}O_2N_4,HI$. The *diacetyl* derivative, $C_{36}H_{24}O_4N_4$, is a red, crystalline powder. When boiled with an alcoholic solution of formaldehyde, the base is converted into the *substance,* $C_{33}H_{22}O_2N$ (orange-yellow crystals), whereas it is transformed by a boiling solution of sodium methoxide in methyl alcohol into the *compound* $C_{32}H_{25}O_2N_4$, canary-yellow, rhombic leaflets. H. W.

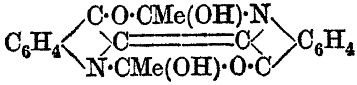
Imines, Anils, and Hydrazones of Indigotin and the Stereochemical Configuration of the Indigoids. W. Madelung and O. Wilhelmi (*Ber.*, 1924, 57, [*B*], 234—241).—The carbonyl and imino groups of indigotin are so indifferent towards the usual reagents that their presence cannot be established in the customary manner. On the other hand, derivatives such as the oximes, phenylhydrazones, and azines can easily be prepared when di-iminoindigotin (Madelung, A., 1913, i, 904) is used as initial material; of these, indigotindioxime has already been described (Madelung, A., 1914, i, 738). The stability of indigotin suggests that there is an intimate connexion between the carbonyl and imino groups such as has been indicated by the constitutions proposed by Claasz (A., 1916, i, 840) and by Lifschitz and Lourié (A., 1917, i, 586). These formulæ do not, however, appear to be satisfactory, since they are valid only for indigotin itself, and cannot be extended to the derivatives of it which are now described; these are very closely related (optically) to indigotin. It is suggested that the oxygen atom of the carbonyl group is joined by a subsidiary valency either to the hydrogen atom of the imino group in the opposite half of the molecule, thus yielding a new six-membered ring, as has been proposed by Scholl (Georgievics, "Die Biziehungen zwischen Farbe u. Konstitution von Farbstoffen," 1920), or to the imino nitrogen atom, thus giving a new five-membered ring.

Indigotinbisphenylhydrazone, $C_{16}H_{10}N_2(:N\cdot NHPh)_2$, red needles, m. p. 219—220° (decomp.), is prepared by the gradual addition of phenylhydrazine to a solution of di-iminoindigotin acetate in glacial acetic acid and subsequent treatment of the hot saturated solution of the product in alcohol with anhydrous potassium carbonate; it separates from acetic acid in green crystals ($+2CH_3\cdot CO_2H$), m. p. 202—204°. The *hydrochloride*, $C_{28}H_{22}N_6,HCl$, green needles, and the *picrate*, $C_{28}H_{22}N_6,2C_6H_3O_7N_3$, green needles, are described. In a similar manner, di-iminoindigotin acetate is converted by hydrazine hydrate into *indigotinazine acetate*, $C_{16}H_{10}O_4,C_2H_4O_2$, long, somewhat unstable needles, m. p. above 300° after previous change; the free base is too unstable to isolate. *Indigotindianilide acetate*, $C_{28}H_{20}N_4,C_2H_4O_2$, dark, bluish-green crystals, is obtained from di-iminoindigotin acetate, aniline, and glacial acetic acid in boiling alcoholic solution; when dissolved in xylene and treated with anhydrous sodium carbonate, it gives the corresponding free base (cf. Grandmougin and Dessoulavy, A., 1910, i, 73). *Dimethyliminoindigotin acetate*, prepared from di-iminoindigotin acetate and methylamine in boiling alcoholic solution, has m. p. 252—254°; the corresponding *base* crystallises in blue needles. The action of acetic anhydride on the imino acetate affords *diacetyliminoindigotin*, aggregates of dark blue needles, m. p. 202°.

Indoleazobenzene, $C_{11}H_{11}N_3$, yellowish-brown crystals, m. p. 133—134°, is prepared by the gradual addition of a methyl-alcoholic solution of indole to an alkaline solution of diazotised aniline. H. W.

Alkyl and Acyl Derivatives of Leuco-indigotin and Indoxyl.

W. MADELUNG (*Ber.*, 1924, **57**, [*B*], 241—252).—A study of the action of benzyl chloride on alkaline solutions of leuco-indigotin leads the author to the conclusion that, contrary to previous views, alkylation leads primarily to the production of *C*-substituted derivatives which readily undergo fission to substituted indoxyls. The formation of two diacetyl-leuco-indigotins is very difficult to interpret; it is suggested that the acetyl groups are not present as such but form a bridge between the hydroxy and imino groups as indicated in the annexed formula. The stereoisomerism is due to the presence of two asymmetric carbon atoms in the two new rings (cf. Madelung and Hagen, A., 1916, i, 840).



$$C_6H_4\genfrac{<}{}{0pt}{}{C\cdot O\cdot CMe(OH)\cdot N}{N\cdot CMe(OH)\cdot O\cdot C}\!>\!C{=}C\!<\!C_6H_4$$

[With O. Haller.]—Indigo white is converted by methyl sulphate in the presence of sodium hydroxide into a dimethyl derivative, rhombic leaflets, m. p. above 235° (decomp.) after darkening at 200° (cf. Grandmougin, A., 1922, i, 470); it gives a *picrate*, dark violet needles, m. p. 173°, and is converted by nitrous acid in the presence of glacial acetic acid into indigotin.

Monobenzyl-leuco-indigotin, $C_{23}H_{18}O_2N_2$, ochre-yellow needles, m. p. 183°, is prepared by the action of benzyl chloride on leuco-indigotin at the ordinary temperature. When an excess of benzyl chloride is used under similar conditions, two isomeric *dibenzyl-leuco-indigotins* are formed. The main product, pale greenish-yellow crystals, m. p. 203°, resembles the dimethyl compound in yielding fluorescent solutions; it is unstable in hot solutions in the presence of acids. It is regarded as the *C*-dibenzyl compound, $C_6H_4<\genfrac{}{}{0pt}{}{CO-}{NH}>C(CH_2Ph)\cdot C(CH_2Ph)<\genfrac{}{}{0pt}{}{CO-}{NH}>C_6H_4$. The second substance, colourless needles, m. p. 192°, is stable in organic media, but more sensitive towards permanganate than its isomeride; it is considered to be the dibenzyl ether of leuco-indigotin. The substance, m. p. 203°, is converted by boiling glacial acetic acid into benzylideneindoxyl, $C_{15}H_{11}ON$.

When treated in alkaline solution with an excess of benzyl chloride at 70—80°, leuco-indigotin suffers fission and the primary products become further benzylated, whereby 2 : 2′-dibenzylindoxyl, yellow crystals, m. p. 174—175° (*nitroso* derivative, pale yellow, lustrous leaflets, m. p. 135°), and 2-*benzylindoxyl benzyl ether*, colourless, slender needles, m. p. 198—199°, are formed; the latter substance is readily oxidised by permanganate, but is stable towards nitrous acid.

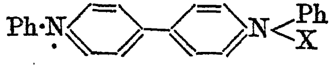
1-Acetylindoxyl gives a *phenylhydrazone*, $C_{16}H_{15}ON_3$, pale yellow needles, m. p. 154°, and an *oxime hydrochloride*, $C_{10}H_{10}O_2N_2,HCl$, colourless needles, m. p. 139°.

Indigotin is converted when heated with acetic anhydride, zinc dust, and acetyl chloride into a *compound*, $C_{20}H_{14}O_3N_2$, yellow needles, m. p. 209—210°, which is regarded as *diacetylanhydroleuco-indigotin*; the success of the preparation depends greatly on the purity of the materials and appears to be governed largely by experimental conditions. H. W.

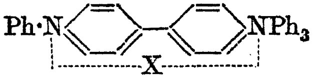
Spectroscopy of the Sulphonated Indigotins. W. C. Holmes (*J. Amer. Chem. Soc.*, 1924, **46**, 208—214).—The absorption spectra of the pure potassium salts of sulphonated indigotin in the visible spectrum have been measured under various conditions. The absorption maxima of the potassium salts in aqueous solution were :

monosulphonate, 608 $\mu\mu$; disulphonate, 610 $\mu\mu$; trisulphonate, 603 $\mu\mu$; tetrasulphonate, 590 $\mu\mu$. Data are supplied for their spectrophotometric identification and evaluation. F. A. M.

Free Ammonium Radicals. V. Comparison of 1 : 1′-Dibenzyl- and 1 : 1′-Diphenyl-4 : 4′-dipyridinium. E. Weitz, T. König, and L. von Wistinghausen (*Ber.*, 1924, **57**, [*B*], 153—175).—Further insight into the constitution of pyridinium radicals is obtained by a study of the reduction of 1 : 1′-diphenyl-4 : 4′-dipyridinium iodide, which has led to the isolation of deeply coloured compounds containing an atom of iodine united with a molecular proportion of the radical. The relationships are similar, but less obvious in the benzyl series (cf. Weitz and König, A., 1922, i, 1186). Compounds of this type are formulated by the authors as semiradicals (I), or intramolecular quinhydrones (II), whereas they



(I.)



(II.)

have been regarded by Emmert (A., 1922, i, 1064) and Dimroth (A., 1923, i, 149) as quinhydrone-like products of the union of molecular proportions of the radical and the dihalogenide.

1 : 1′-Dibenzyl-4 : 4′-dipyridinium subiodide (cf. Emmert and Varenkamp, A., 1922, i, 1064) is obtained by the reduction of the di-iodide with metals or, more conveniently, by the action of the di-iodide on the radical; it crystallises in coarse platelets with a metallic reflex, m. p. about 190°, according to the rate of heating. It is reduced to the free radical by metallic sodium or an excess of dibenzyldipyridinium in alcoholic solution. The corresponding subchloride is isolated in blackish-violet, rhombohedral crystals, m. p. about 190° when rapidly heated; the molecular weight in boiling methyl alcohol is about half that required by the formula, $C_{24}H_{22}N_2Cl$.

1-Phenylpyridinium chloride, m. p. 105° (corresponding *perchlorate*, colourless needles, m. p. 221°), is conveniently prepared by boiling the so-called " pyridine dye " (from dinitrophenylpyridinium chloride or pyridine cyanobromide and aniline) with alcohol and concentrated hydrochloric acid and addition of ferric chloride solution; the additive salt, $C_{11}H_{10}NCl,FeCl_3$, is subsequently decomposed by the requisite amount of sodium carbonate. It is reduced by sodium amalgam in aqueous solution mainly to 1-*phenyl*-$\Delta^{1\cdot 4}$(?$\Delta^{1\cdot 2}$)-*dihydropyridine*, transparent crystals, m. p. 49—50° (the constitution of which is deduced from its properties, its molecular weight, and its conversion by iodine into 1-phenylpyridinium iodide); *bis*-1-*phenylpyridinium* [1 : 1′-*diphenyltetrahydro*-4 : 4′-*dipyridyl*],  $Ph\cdot N{<}{}^{CH:CH}_{CH:CH}{>}CH\cdot CH{<}{}^{CH:CH}_{CH:CH}{>}N\cdot Ph$, silvery leaflets, m. p. 136° (decomp.) after darkening at 100° when rapidly heated, is produced in minor amount. If, however, the reduction is effected in permanently neutral or faintly acid solution (for example, by sodium amalgam in the presence of aluminium sulphate), the leuco compound is alone formed; on the other hand, the dihydro product is almost exclusively produced if the solution is made alkaline from the commencement of the experiment. The action of iodine on 1 : 1′-diphenyltetrahydro-4 : 4′-dipyridyl proceeds in a complex manner, yielding 1 : 1′-diphenyl-4 : 4′-dipyridinium di-iodide, red prisms, m. p. about 360° (cf. König, A., 1923, i, 382); the corresponding perchlorate and picrate have m. p. 311° and 244°, respectively, whereas König (*loc. cit.*) gives m. p. 299° and 170°; 1-*phenylpyridinium iodide*, colourless, flattened prisms or anhydrous leaflets, m. p. 210° after darkening above 100°, is also produced, whilst about half the original material remains in the chloroform.

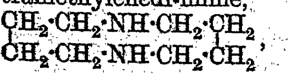
1 : 1′-*Diphenyl*-4 : 4′-*dipyridinium*,  is most conveniently prepared by dissolving 1 : 1′-diphenyltetrahydro-4 : 4′-dipyridyl in a warm mixture of pyridine and methyl alcohol and preserving the mixture in a closed, half-filled flask for about a week; it separates from the solution in red, rhombic crystals with a vivid blue reflex, decomp. above 180°. It decomposes readily when exposed to air. It is converted by iodine in all solvents with the exception of benzene, primarily into the subiodide (below) and finally into the red di-iodide. The radical may also be prepared by the reduction of an aqueous solution of the di-iodide with zinc dust. 1 : 1′-*Diphenyl*-4 : 4′-*dipyridinium subiodide*,

$$Ph\cdot C_5H_5\dot{N}\cdot C_5H_5NPhI,$$

is most conveniently prepared by mixing equivalent quantities of diphenyldipyridinium di-iodide and the corresponding leuco compound dissolved in acetone or chloroform; it crystallises in lustrous, steel-blue prisms, m. p. 318—319° (decomp.).

1 : 1′-Diphenyltetrahydro-4 : 4′-dipyridyl dissolved in chloroform is converted by a mixture of oxygen and carbon dioxide into 1 : 1′-*diphenyl*-4 : 4′-*dipyridinium hydrogen subcarbonate*, short prisms which appear violet by reflected, nearly black by transmitted light. The product is also obtained when a mixture of nitric oxide and carbon dioxide is used. H. W.

Cyclic Di-imines and their Decomposition. III. J. VON BRAUN, G. BLESSING, and F. ZOBEL (*Ber.*, 1924, **57**, [*B*], 185—191; cf. A., 1923, i, 840).—The catalytic hydrogenation of γ-phenoxy-*n*-butyronitrile in amyl-alcoholic solution (cf. A., 1923, i, 1088) gives a mixture of δ-phenoxybutylamine and di-δ-phenoxybutylamine; when subjected to slow distillation, the secondary base is transformed into phenol and *phenoxybutylpyrrolidine*, a colourless liquid, b. p. 170°/13 mm. (the hygroscopic *hydrochloride*, the *picrate*, yellow needles, m. p. 110°, and the *methiodide*, m. p. 123°, are described). It is converted by fuming hydrobromic acid at 100° into δ-*bromobutylpyrrolidine* (identified as the *chloroplatinate*, m. p. 133—134° after softening at about 130°), which is readily transformed into dipyrrolidinium bromide (cf. von Braun, A., 1916, i, 631). The salt is slowly converted by concentrated ammonia at 170—180° into ditetramethylenedi-imine,



$$\begin{array}{l}CH_2\cdot CH_2\cdot NH\cdot CH_2\cdot CH_2\\CH_2\cdot CH_2\cdot NH\cdot CH_2\cdot CH_2\end{array},$$

a colourless liquid, b. p. 95°/12 mm., d_4^{18} 0·902; the hygroscopic *hydrochloride*, the *chloroplatinate*, yellowish-red crystals, decomp. 207°, the *picrate*, m. p. 203—204°, the *benzenesulphonyl* compound, the *nitroso* derivative, the exceedingly hygroscopic *dimethiodide*, and the corresponding *chloride* and *chloroplatinate*, decomp. 257°, are described.

Tetramethylenepentamethylenedi-imine, a liquid, b. p. 110—112°/14 mm., d_4^{11} 0·920, is prepared similarly from the corresponding bromide; it yields a non-crystalline *benzenesulphonyl* derivative and *picrate*, a hygroscopic *hydrochloride*, a *chloroplatinate*, decomp. 190°, and a *di-methiodide*, $C_{13}H_{30}N_2I_2$, m. p. 247°, which is transformed through the *chloride* into the corresponding *chloroplatinate*, decomp. 248°.

Treatment of dipiperidinium bromide with aqueous ammonia (cf. A., 1907, i, 151) leads to the isolation of very small yields of *dipentamethylenedi-imine* (*dipiperidine*), b. p. 108—110°/12 mm., d_4^{17} 0·9195. The non-crystalline *picrate* and *nitroso* derivative, the hygroscopic *hydrochloride*, and the *chloroplatinate*, an orange-coloured, crystalline powder, decomp. 180°, are described. The *dimethiodide*, m. p. 272° (decomp.), and the corresponding *chloroplatinate*, decomp. 247°, have been prepared. H. W.

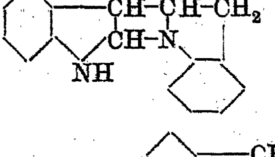
Discatole. B. ODDO and G. B. CRIPPA (*Atti R. Accad. Lincei*, 1924, [v], **33**, i, 31—34).—*Discatole*, $C_{18}H_{18}N_2$, obtained as hydrochloride by subjecting scatole, in anhydrous ethereal solution, to the action of a slow current of hydrogen chloride, forms white needles, m. p. 130°, and is free from the fæcal odour of scatole itself. Its *hydrochloride*, $C_{18}H_{18}N_2,HCl$, forms microscopic, highly refractive, prismatic crystals, m. p. 173°; its orange-red *picrate*,

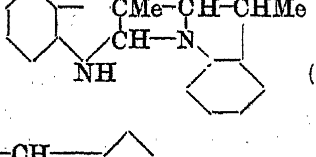
$$C_{18}H_{18}N_2,C_6H_3O_7N_3,$$

m. p. 170°, and its colourless *oxalate*, $(C_{18}H_{18}N_2)_2,C_2H_2O_4$, m. p. 180°, are described. It has not been found possible to obtain a triscatole.

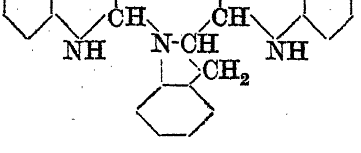
These results, in conjunction with the facts that indole gives both a dimeride and a trimeride, that 2-methylindole undergoes no such polymerisation, and that any of these polymerides yields only a mono-hydrochloride, indicate for di-indole, discatole, and tri-indole the formulæ (I), (II), and (III), respectively:

(I.)





(II.)



(III.)

T. H. P.

Dyes derived from Acenaphthenequinone. A. C. Sircar and S. K. Guha (*J. Chem. Soc.*, 1924, **125**, 335—340).—Azines produced by the condensation of acenaphthenequinone and of its 3 : 4-dinitro derivative with *o*-diamines, possess tinctorial properties not inferior to those of the corresponding derivatives of phenanthraquinone. Although insoluble in water, they can be used when freshly precipitated for dyeing wool. The azine sulphonic acids and azonium derivatives are also satisfactory dyestuffs. The reduction products of the 3 : 4-dinitroazines have probably the diaminodihydroazine structure (cf. T., 1922, **121**, 1950). Attempts to prepare 3-nitroacenaphthenequinone by the method of Rowe and Davies (T., 1920, **117**, 1349) always yielded a product containing the dinitro derivative. The following substances are described: *acenaphthatolazine*, $C_{12}H_6{<}^{N}_{N}{>}C_6H_3Me$, light brown needles, m. p. 232°. *Acenaphthanaphthazine*,

$$C_{12}H_6{<}^{N}_{N}{>}C_{10}H_6,$$

brownish-yellow needles, m. p. 290°. 3 : 4-*Dinitroacenaphthatolazine*, $(NO_2)_2C_{12}H_4{<}^{N}_{N}{>}C_6H_3Me$, orange-yellow needles, m. p. not below 290°. 3 : 4-*Dinitroacenaphthanaphthazine*,

$$(NO_2)_2C_{12}H_4{<}^{N}_{N}{>}C_{10}H_6,$$

scarlet-red, shining needles, m. p. not below 290°. 3 : 4-*Dinitroacenaphthaphenazine*, $(NO_2)_2C_{12}H_4{<}^{N}_{N}{>}C_6H_4$, orange-yellow plates, m. p. not below 290°. 3 : 4-*Dinitroacenaphthaphenazinazine*, $(NO_2)_2C_{12}H_4{<}^{N}_{N}{>}C_6H_2{<}^{N}_{N}{>}C_6H_4$, red, prismatic needles, no m. p. *Acenaphthanaphthazine-5′-sulphonic acid*, $C_{12}H_6{<}^{N}_{N}{>}C_{10}H_5{\cdot}SO_3H$, microscopic, brownish-yellow needles, m. p. not below 300°. 3 : 4-*Dinitroacenaphthanaphthazine-5′-sulphonic acid*, brown, amorphous precipitate. *Phenylacenaphthanaphthazonium chloride*,

$$C_{12}H_6{<}^{N\text{———}}_{NPhCl}{>}C_{10}H_6,$$

greenish-black powder, m. p. not below 290°. *Phenyl*-3 : 4-*dinitroacenaphthanaphthazonium chloride*, similar, m. p. 270°. *Naphthylacenaphthaphenazonium chloride*, dull, black powder, m. p. not below 290°. 3 : 4-*Diamino*-7 : 12-*dihydroacenaphthaphenazine*,

$$(NH_2)_2C_{12}H_4{<}^{NH}_{NH}{>}C_6H_4,$$

orange-red prisms, m. p. (with sublimation) above 290°. 3 : 4-*Diamino*-7 : 12-*dihydroacenaphthanaphthazine*, scarlet-red, rectangular plates. 3 : 4-*Dihydroxy*-7 : 12-*dihydroacenaphthaphenazine*, brick-red powder, subliming above 290°. F. G. W.

Action of Hydrazine on Uracil and Thymine. R. Fosse, A. Hieulle, and L. W. Bass (*Compt. rend.*, 1924, **178**, 811—813).—Uracil reacts with hydrazine to give carbamide and pyrazolone, the latter with xanthhydrol affording 1 : 2- or 1 : 4-*dixanthylpyrazolone*, colourless filaments, colouring at 195° and melting at 210—213° to a red liquid. Thymine, treated successively with hydrazine hydrate and xanthhydrol, affords dixanthylcarbamide and *dixanthyl*-4-*methylpyrazolone* (colourless crystals, m. p. about 202°), this substance also resulting by the action of xanthhydrol on the crude condensation product from hydrazine and ethyl formylpropionate. E. E. T.

Oxidation Products of Bilirubin. Detection of Urobilin. A. ADLER.—(See ii, 280.)

5-Nitrobarbituric Acids. H. BILTZ and K. SEDLATSCHECK (*Ber.*, 1924, **57**, [*B*], 339—349).—Violuric acid, decomp. 240—241° after darkening at 220° (cf. Biltz and Hamburger, A., 1916, i, 505) is converted by concentrated nitric acid into 5-nitrobarbituric acid, decomp. 180—181°, the yield being about 95% of that theoretically possible. The latter acid when suspended in ice-cold water and treated with chlorine yields 5-*chloro*-5-*nitrobarbituric acid*,

$CO<\begin{matrix}NH\cdot CO\\NH\cdot CO\end{matrix}>CCl\cdot NO_2$, colourless, slender needles, decomp. 86—87°, which is decomposed by warm water into nitrobarbituric acid, carbamide, and chloropicrin and by bleaching powder solution into chloropicrin and carbamide. 5-*Bromo*-5-*nitrobarbituric acid*, long, slender needles, decomp. 108°, is decomposed by warm water in the same manner as the chloro compound. The position of the halogen atom in these acids is established by the observation that they are transformed by diazomethane into 5-halogeno-5-nitro-1 : 3-dimethylbarbituric acids (see later).

5-*Nitro*-1-*methylbarbituric acid*, $C_5H_5O_5N_3,2H_2O$, colourless, slender needles, decomp. 142—143°, is prepared in 92% yield from methylvioluric acid; the *ammonium, potassium, sodium* (+H_2O), and *barium* (+H_2O) salts are described. The acid is remarkably stable towards solutions of alkali hydroxides. 5-*Chloro*-5-*nitro*-1-*methylbarbituric acid*, colourless, hexagonal plates, decomp. 122—123°, is decomposed completely by boiling water into nitromethylbarbituric acid, methylcarbamide, chloropicrin, and carbon dioxide. 5-*Bromo*-5-*nitro*-1-*methylbarbituric acid* forms colourless, four-sided prisms, m. p. 137—138°.

5-Nitro-1 : 3-dimethylbarbituric acid, small, colourless needles, decomp. 148—149° (the sodium and *potassium* salts are described), is converted into 5-chloro-5-nitro-1 : 3-dimethylbarbituric acid, decomp. 150°, and 5-bromo-5-nitro-1 : 3-dimethylbarbituric acid, decomp. 152°.

5-*Nitro*-1-*ethylbarbituric acid*, $C_6H_7O_5N_3,H_2O$, forms colourless needles, decomp. 132—133°; the *ammonium, potassium, sodium, calcium*, and *strontium* salts are described. 5-*Chloro*-5-*nitro*-1-*ethylbarbituric acid* crystallises in colourless, rhombic leaflets, decomp. 127—128°. 5-*Bromo*-5-*nitro*-1-*ethylbarbituric acid* is a heavy, microcrystalline powder, decomp. 138—139°.

5-*Nitro*-1 : 3-*diethylbarbituric acid*, colourless octahedra, decomp. 116—117°, is prepared from diethylvioluric acid; it may also be obtained in poorer yield by the direct nitration of 1 : 3-diethylbarbituric acid, whereby diethylalloxan and tetraethylalloxantin are also produced; the *ammonium* salt, long, colourless needles, is described. 5-*Chloro*-5-*nitro*-1 : 3-*diethylbarbituric acid*, a heavy, crystalline precipitate, decomp. 53°, and 5-*bromo*-5-*nitro*-1 : 3-*diethylbarbituric acid*, a heavy, micro-crystalline powder, decomp. 63—64°, have been prepared.

Evidence is adduced against the existence of violantin and its alkyl derivatives. H. W.

Acetonylbarbituric Acid and some of its Derivatives. A. W. Dox and B. Houston (*J. Amer. Chem. Soc.*, 1924, **46**, 252—256).—The acetonyl group may be introduced directly at carbon atom 5 of barbituric acid by means of chloroacetone. Further substitution by halogen is readily effected, or by allyl, benzyl, and acetonyl. The less reactive alkyl halides, such as butyl bromide, do not react readily with acetonylbarbituric acid, but the acetonyl and alkyl groups may be introduced in the reverse order by treatment of the monoalkylbarbituric acid with chloroacetone. The acetonylalkylbarbituric acids are much less effective as hypnotics than the dialkylbarbituric acids with the same length of side chains.

It was not found possible to prepare ethyl acetonylmalonate from sodiomalonic ester and chloroacetone, but barbituric acid itself was alkylated readily in boiling aqueous solution.

Acetonylbarbituric acid forms flat, yellow crystals, m. p. 238—240° (decomp.); it liberates acetic acid from its salts. Halogenation yielded respectively *acetonylbromobarbituric acid*, white needles, decomp. about 143° without melting, and *acetonylchlorobarbituric acid*, white needles, which begin to decompose about 175° and melt about 245°. The following dialkylated acids were prepared by further treatment of acetonylbarbituric acid in the usual manner: *diacetonylbarbituric acid*, white needles, m. p. 264—266° (decomp.), *acetonylallylbarbituric acid*, large, white crystals, m. p. 216—217°, *acetonylbenzylbarbituric acid*, large, prismatic crystals, m. p. 224—225°; *acetonylethylbarbituric acid*, flat, white crystals, m. p. 238—239°. F. A. M.

Velocity of Spontaneous Oxidation of Uric Acid in Alkaline Solution. L. Piaux (*Compt. rend.*, 1924, **178**, 637—640; cf. Biltz and Robl, A., 1920, i, 883, and More, this vol., i, 315).—An aqueous solution containing 5 mols. of potassium hydroxide to 1 mol. of uric acid rapidly absorbs oxygen; with a smaller porportion of base oxidation is less rapid. A considerable quantity of ammonia is formed. On acidifying, carbon dioxide is evolved, and addition of alcohol then causes the precipitation of potassium oxonate, $C_4H_2O_4N_3K$. The main reaction may be written thus: $C_5H_4O_3N_4+O_2+H_2O=CO_2+NH_3+C_4H_3O_4N_3$.

Since allantoin was not formed in these oxidation processes, the author examined the action of air (1) on an alkaline solution of potassium allantoate, and (2) on an alkaline solution of uric acid which had previously (by means of permanganate) been oxidised to the extent of 1 atom of oxygen. (Solution 2, according to Biltz and others [*loc. cit.*] contains a substance which is oxidisable to an oxonate.) Neither (1) nor (2) absorbed oxygen.

E. E. T.

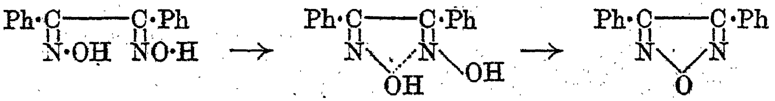
Action of Catalysts on the Oxidation of Uric Acid. Iron and Manganese (Hydroxides). L. PIAUX (*Compt. rend.*, 1924, **178**, 782—785; cf. preceding abstract).—The aërial oxidation of uric acid (1 mol.) in potassium hydroxide (5 mols.) solution, is accelerated by traces of ferric hydroxide, potassium oxonate being formed. Manganese oxide hydrates (obtained by using manganese lactate) accelerate the initial aërial oxidation but diminish the amount of oxonate formed, none of the latter being obtained when 1 mol. of lactate is originally taken per 5·6 mols. of uric acid. Allantoin takes its place, and is formed from the intermediate compound described by Biltz and Behrend (cf. A., 1921, i, 893).

E. E. T.

Ethylated Uric Acids. H. BILTZ and K. SEDLATSCHEK (*Ber.*, 1924, **57**, [*B*], 175—182).—The action of ethyl bromide on dipotassium urate in the presence of carbon tetrachloride at 110° leads to the production of moderate yields (12—13%) of 3 : 7 : 9-triethyluric acid, colourless aggregates of needles, m. p. 204°; the product is probably identical with the triethyluric acid obtained by Drygin in 1864 by the action of ethyl iodide on lead urate. The constitution of the acid is deduced from its oxidative degradation to *diethylalloxantin*, $C_{12}H_{14}O_8N_4,H_2O$, large, transparent crystals, m. p. 209°, and 1-*ethylalloxan*, $C_6H_6O_4N_2,H_2O$, slender needles, m. p. 103° (decomp.); the latter substance is transformed by hydroxylamine hydrochloride into the previously described 1-ethylvioluric acid. Two of the ethyl groups of the triethyluric acid must therefore be present in the glyoxalone ring, that is, in positions 7 and 9, whilst the third must occupy position 3, since the alkylated compound is prepared from the solid potassium salt. As recorded by Drygin, when 3 : 7 : 9-triethyluric acid is warmed with concentrated hydrochloric acid, an ethyl group is eliminated as ethyl chloride and 3 : 7-*diethyluric* acid, slender, rhombic leaflets, m. p. 350—355°, is almost quantitatively produced; the same change occurs under the conditions of Zeisel's alkoxy determination. The presence of an ethyl group in position 3 is proved by oxidation of the acid to diethylalloxantin and ethylalloxan, m. p. 103°, whilst the second ethyl group necessarily occupies position 7, since fission of the acid with concentrated hydrochloric acid at 170° leads to the production of ethylglycine hydrochloride, which is identified by transforming it into 1-ethylhydantoin. 3 : 7 : 9-Triethyluric acid is readily converted by diazomethane in ethereal solution in the presence of a little water into 1-*methyl*-3 : 7 : 9-*triethyluric acid*, long, colourless needles, m. p. 104°. 1 : 3 : 7 : 9-*Tetraethyluric acid*, aggregates of slender needles, m. p. 82°, is prepared similarly with the aid of diazoethane. Treatment of the tetra-alkyl compounds with concentrated hydrochloric acid leads to the production of 1-*methyl*-3 : 7-*diethyluric acid*, feathery aggregates of needles, m. p.

257—258°, and 1 : 3 : 7-*triethyluric acid*, colourless needles, m. p. 218—219°. H. W.

The Beckmann Transformation. II. J. MEISENHEIMER and W. LAMPARTER (*Ber.*, 1924, **57**, [*B*], 276—282).—Reasons have previously been advanced (Meisenheimer, A., 1922, i, 152) in favour of a redistribution of formulæ among the benzildioximes whereby the α-dioxime receives the *anti*-, the β-dioxime the *syn*-, and the γ-dioxime retains the *amphi*-configuration. The tendency of the dioximes to lose water has been examined by heating in evacuated tubes at 155°; under these conditions, the α-dioxime is volatilised most slowly and with partial isomerisation to the β-dioxime; the latter sublimes more readily without undergoing decomposition, whereas only the γ-dioxime loses water and forms an anhydride; transformation into the β-dioxime accompanies the latter action and the formation of the anhydride ceases as soon as the isomerisation is complete. The behaviour of the oximes themselves is in harmony with that of their acetates, since the derivatives of the α- and β-forms are hydrolysed by cold sodium hydroxide solution to the corresponding oximes, whereas the diacetate of the γ-variety yields the anhydride. The behaviour of the dibenzoates exactly resembles that of the diacetates. The observations necessitate a new conception of the mechanism of anhydride formation, that represented in the following scheme being suggested:



Dibenzoyl-α-benzildioxime, prepared from the α-dioxime and benzoyl chloride in the presence of pyridine, crystallises in colourless needles, m. p. 220°; *dibenzoyl-β-benzildioxime*, m. p. 157—158°, and *dibenzoyl-γ-benzildioxime*, m. p. 135°, are described. Benzoyl-α-benzilmonoxime, m. p. 96°, is obtained from the α-oxime and benzoic anhydride at 60—70°; it is reduced by zinc dust and glacial acetic acid to deoxybenzoin and, in this respect, it resembles the α-oxime. It is therefore regarded as a simple derivative of the latter and not as *ON*-dibenzoyl*iso*benzamide, OBz·CPh:NBz (cf. Werner and Piguet, A., 1905, i, 66; Meisenheimer, *loc. cit.*). Acetyl-α-benzilmonoxime, m. p. 67—68°, can be prepared from the α-monoxime and acetyl chloride in pyridine solution.

The conversion of diacetyl-β-benzildioxime, m. p. 124—125°, when heated above its melting point into a product, m. p. 148°, is accompanied by very slight loss in weight. When hydrolysed by sodium hydroxide, the latter substance gives mainly β-benzildioxime mixed with traces of the anhydride; it is therefore regarded as a dimorphous form of the ordinary diacetyl-β-benzildioxime containing small quantities of diacetyl-γ-benzildioxime.

δ-Benzildioxime (cf. Atack and Whinyates, T., 1921, **119**, 1184) is shown (cf. Brady and Dunn, this vol., i, 292) to be a mixture of much α- with little β-dioxime. H. W.

The Beckmann Transformation. III. J. Meisenheimer and H. Lange (*Ber.*, 1924, **57**, [*B*], 282—289).—A continuation of previous work (Meisenheimer, A., 1922, i, 152).

3 : 5-*Diphenyl*-4-p-*anisyl*isooxazole,  $OMe\cdot C_6H_4<\begin{matrix}CPh\cdot O\\ CPh{:}N\end{matrix}$, m. p. 189° (cf. Meisenheimer and Weibezahn, A., 1922, i, 176), prepared by the action of boiling sodium hydroxide solution on α-nitro-4-4-methoxystilbene, is converted by ozone in the presence of carbon tetrachloride into *benzoyl*-β-4′-*methoxybenzil*-7-*oxime*,

$$OMe\cdot C_6H_4\cdot CO\cdot C(Ph){:}N\cdot OBz,$$

colourless, prismatic plates, m. p. 95·5—96·5°, the configuration of which is thus established. This compound is also produced by the benzoylation of the 4′-methoxybenzil-7-oxime obtained by Meisenheimer and Jochelson (A., 1907, i, 858) from α-nitro-*p*-methoxystilbene; on hydrolysis, it gives the β-oxime and benzoic acid. The oxime is therefore the β-compound. This conclusion is confirmed by the observation that the oxime is converted by phosphorus pentachloride in the presence of ether into *anisoylformanilide*, $OMe\cdot C_6H_4\cdot CO\cdot CO\cdot NH\cdot Ph$, slender, yellow needles, m. p. 106—107° (the synthesis of which from anisoylformic acid is described). *Acetyl*-β-4′-*methoxybenzil*-7-*oxime*, obtained from the β-oxime and boiling acetic anhydride, forms coarse crystals, m. p. 85—86°.

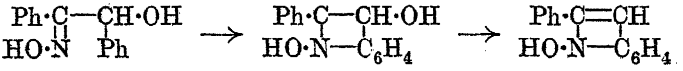
α-4′-*Methoxybenzil*-7-*oxime*, slender, colourless needles, m. p. 87·5—89°, is prepared by the action of amyl nitrite and sodium ethoxide on *p*-methoxydeoxybenzoin or (better) by treatment of 4′-methoxybenzil-7-oxime-7 : 7′-dimethylacetal,

$$OMe\cdot C_6H_4\cdot C(OMe)_2\cdot CPh{:}N\cdot OH$$

(cf. Meisenheimer and Jochelson, *loc. cit*), with boiling glacial acetic acid. *Acetyl*-α-4′-*methoxybenzil*-7-*oxime*, prepared from the oxime and boiling acetic anhydride, forms coarse, colourless crystals, m. p. 133—134°. *Benzoyl*-α-4′-*methoxybenzil*-7-*oxime*, obtained by benzoylation of the parent substance in the presence of pyridine or from the α-oxime and benzoic anhydride at 40—50°, crystallises in slender, colourless needles, m. p. 137·5—138·5°; it is converted by aqueous-alcoholic sodium hydroxide solution into benzonitrile and benzoic and anisic acids. α-4′-*Methoxybenzil*-7-*oxime methyl ether*, colourless, transparent plates, m. p. 62—63°, is isomerised to the methyl ether of the β-oxime by protracted treatment with hot, concentrated hydrochloric acid.

The view of Meisenheimer and Heim (A., 1907, i, 858) that 4′-methoxybenzil-7-oxime-7′ : 7′-dimethylacetal belongs to the α-series is confirmed by the observations that its methyl ether and *benzoyl* derivative (colourless needles or prisms, m. p. 127—128° dependent on the rate of heating) are converted by glacial acetic acid into the α-oxime or its derivatives, and that the oxime, when dissolved in glacial acetic acid and acetic anhydride, is converted by hydrogen chloride into benzonitrile and anisic acid. H. W.

The Beckmann Transformation. IV. J. Meisenheimer and H. Meis (*Ber.*, 1924, **57**, [*B*], 289—297).—In connexion with the new conception of the course of the Beckmann transformation (cf. Meisenheimer, A., 1922, i, 152), the behaviour of a number of ortho-substituted benzophenoneoximes has been examined. Although not conclusive in any case, the results generally favour the authors' views. The only case recorded in the literature in which the stereochemical configuration of an oxime is definitely established and harmonises with the older conception of the Beckmann transformation is that of benzoin-α-oxime, which, according to Fischer and Hütz (A., 1895, i, 371), is converted by concentrated sulphuric acid into a derivative of indole, whereas the β-oxime does not behave in this manner. Doubts as to the constitution of the product have been expressed by Fischer (A., 1896, i, 696), but the definite proof that it is not 2-phenylindoxyl is afforded by the synthesis of the latter (Kalb and Bayer, A., 1912, i, 727) and its non-identity with the product obtained by Fischer and Hütz. Loss of water from benzoin-α-oxime must therefore occur in accordance with the scheme:



$$\begin{array}{l}\mathrm{Ph\cdot C{-}CH\cdot OH}\\ \mathrm{HO\cdot N\quad Ph}\end{array} \longrightarrow \begin{array}{l}\mathrm{Ph\cdot C{-}CH\cdot OH}\\ \mathrm{HO\cdot N{-}C_6H_4}\end{array} \longrightarrow \begin{array}{l}\mathrm{Ph\cdot C{=}CH}\\ \mathrm{HO\cdot N{-}C_6H_4}\end{array}$$

which necessitates a transposition of the configurations assigned previously to the α- and β-oximes. The modified conception of the course of the reaction explains the inability of deoxybenzoinoxime or phenylacetaldoxime to give a derivative of indole and the conversion of methylbenzoinoxime and benzoinoxime into the same product. The observation that acetyl-β-benzoinoxime can be oxidised to acetyl-β-benziloxime establishes the relationship between the benzoin- and benzil-oximes, which are thereby brought into complete harmony with one another.

o-Benzoylbenzoic acid is converted by hydroxylamine into an oxime-anhydride, $\begin{array}{l}\mathrm{CPh{=}N}\\ \mathrm{C_6H_4\cdot CO}\end{array}\!\!>\mathrm{O}$, m. p. 163—164°, which is unaffected by the customary reagents of the Beckmann change but is converted by concentrated sulphuric acid into phthalanil, whereby the oximino oxygen atom changes place with the oppositely situated phenyl radical. *o*-Chloro- and *o*-bromo-benzophenoneoximes lose halogen acid when treated with concentrated sodium hydroxide solution and yield the compound $\mathrm{C_6H_4}{<}\begin{array}{c}\mathrm{CPh}\\ \mathrm{O}\end{array}{>}\mathrm{N}$, thus rendering the configuration $\begin{array}{l}\mathrm{Br\cdot C_6H_4\cdot C\cdot Ph}\\ \quad\quad\;\;\mathrm{HO\cdot N}\end{array}$ probable. When treated with ether and phosphorus pentachloride they are converted into *o*-chloro- and *o*-bromo-benzanilide; benzoic *o*-chloro(*o*-bromo)-anilide is not produced, as would be expected from an oxime of the proposed configuration in accordance with the older view of the Beckmann transformation. For analogous reasons, the *syn*-configuration is assigned to the only known form of *o*-hydroxybenzophenoneoxime; it is converted by phosphorus pentachloride into salicylanilide accompanied by small amounts of anhydrobenzoyl-

o-aminophenol,  $C_6H_4{<}{}^{O}_{N}{>}CPh$, which can be derived only from the stereoisomeric oxime.

o-Aminobenzophenoneoxime exists in two stereoisomeric forms,  $\begin{matrix}NH_2\cdot C_6H_4\cdot CPh\\ \|\\ HO\cdot N\end{matrix}$, m. p. 156°,  $\begin{matrix}NH_2\cdot C_6H_4\cdot CPh\\ \|\\ N\cdot OH\end{matrix}$, m. p. 126°, the configurations of which are deduced from their behaviour when diazotised. The oxime of higher melting point is transformed by phosphorus pentachloride into the anilide of anthranilic acid, whereas crystalline products are not isolated from the isomeride of lower melting point.

2 : 4-Dimethylbenzophenone-2′-carboxylic acid gives only a single *oxime-anhydride*,  $\begin{matrix}CO\cdot C_6H_4\\ |\\ O\text{———}N\end{matrix}{>}C\cdot C_6H_3Me_2$, cubic crystals, m. p. 133—134°, which is transformed by concentrated sulphuric acid into 1 : 2 : 4-xylidine and phthalic acid. *Methyl* 2 : 4-*dimethylbenzophenone-2′-carboxylate*, coarse, colourless crystals, m. p. 69—70°, b. p. 209—210°/10 mm., could not be caused to react with hydroxylamine.

Mandelanilide is transformed by concentrated sulphuric acid at the ordinary temperature into *phenyloxindole*,  $C_6H_4{<}\begin{matrix}\text{———}N\\ CHPh\end{matrix}{>}C\cdot OH$, colourless, cubic crystals, m. p. 185—187°, but the yields are poor in consequence of simultaneous sulphonation. Mandel-*p*-toluidide, on the other hand, is converted quantitatively into 5-*methyl*-3-*phenyloxindole*, m. p. 211°. H. W.

p-Nitrobenzeneazopyrogallol (Chrome Brown P.A.). P. JUILLARD (*Mon. Sci.*, 1924, **14**, 25—27).—An account of work already published (A., 1923, i, 1139). E. H. R.

Symmetrical Di*cyclo*hexylhydrazine and Related Compounds. H. H. HARKINS and H. L. LOCHTE (*J. Amer. Chem. Soc.*, 1924, **46**, 450—455).—The authors have investigated the reduction of *cyclo*hexylideneazine by Skita's method. In no experiment did they obtain the unsymmetrical di*cyclo*hexylhydrazine described by Kijner and Beloff (A., 1911, i, 678).

s-*Di*cyclo*hexylhydrazine* (*hydrazo*cyclo*hexane*) (*hydrochloride*, white needles, m. p. 271° [corr.]) is very unstable in air, and has m. p. 6—10°; b. p. 260—270°/740 mm.; d_4^{27} 0·9384; n_D^{33} 1·4888. The crystalline *oxalate* and unstable *nitroso* derivative are also described.

*Azo*cyclo*hexane*, $C_6H_{11}\cdot N\colon N\cdot C_6H_{11}$, from di*cyclo*hexylhydrazine by oxidation with bromine water, forms straw-coloured needles, m. p. 34·5°. By hydrolysis of the azo compound with hydrochloric acid, *cyclo*hexylhydrazine (Kijner, *loc. cit.*) is obtained; the thioureide has m. p. 148°, instead of 143° (Kijner); the *benzylidene* compound $(C_6H_{11}\cdot N\cdot N\colon CHPh)_2CHPh$, colourless needles, has m. p. 183° (corr.). cyclo*Hexanone* cyclo*hexylhydrazone peroxide*,

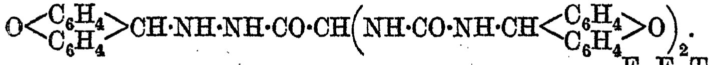
$$C_6H_{11}\cdot NH\cdot \underline{N\cdot O\cdot O\cdot C_6H_{10}},$$

is formed by the interaction of equivalent amounts of *cyclo*hexylhydrazine and *cyclo*hexanone. It crystallises in fine, white needles, m. p. 76° (decomp.), or when slowly heated, 74°. In contact with air it changes into an oil and a crystalline *substance*, m. p. 136—137°, neither of which has been identified. Attempts to obtain the free *cyclo*hexanone *cyclo*hexylhydrazone in the solid form failed.

Attempts to reduce di*cyclo*hexyl nitrosoamine to as.-di*cyclo*hexylhydrazine by Fischer's method were unsuccessful. A. B. S.

Action of Hydrazine on Hydantoin and Allantoin. R. Fosse, P. Hagène, and R. Dubois (*Compt. rend.*, 1924, **178**, 578—581).—Hydrazine hydrate converts hydantoin, at the ordinary temperature, into hydantoylhydrazide (A., 1923, i, 938). Hydantoylhydrazide affords sparingly soluble crystalline precipitates with aqueous solutions of benzaldehyde and anisaldehyde. *Benzylidenehydantoylhydrazone*, $CHPh{:}N\cdot NH\cdot CO\cdot CH_2\cdot NH\cdot CO\cdot NH_2$, has m. p. 206—209° (decomp. and varying with rate of heating); p-*methoxybenzylidenehydantoylhydrazone* becomes coloured at 215—220° and melts at 220—227°, the temperatures varying with rate of heating.

Allantoin is converted by hydrazine into the *monohydrate* of *allantoylhydrazide*, $NH_2\cdot NH\cdot CO\cdot CH(NH\cdot CO\cdot NH_2)_2,H_2O$. The anhydrous hydrazide has m. p. 185° (decomp.). Allantoylhydrazide (1 mol.) condenses with xanthhydrol (3 mols.) to give a *substance* (annexed formula), having m. p. 223—225° (decomp.).



$$O{<}\substack{C_6H_4\\C_6H_4}{>}CH\cdot NH\cdot NH\cdot CO\cdot CH\left(NH\cdot CO\cdot NH\cdot CH{<}\substack{C_6H_4\\C_6H_4}{>}O\right)_2.$$

E. E. T.

Additive Products of the Phosphineimines. M. Masriera (*Anal. Fís. Quím.*, 1924, **22**, 25—48; cf. this vol., i, 234).—A continuation of earlier work on the additive compounds derived from phosphineimines. Acetylphenylchloroamide gives with triphenylphosphine an additive *compound*, probably $Cl\cdot PPh_3\cdot NPhAc$, which is thought to be isomeric with the unstable compound formed from triphenylphosphinephenylimine and acetyl chloride. It is stable in air and forms white tablets having m. p. 109°. Triphenylphosphine and *p*-toluenesulphonephenylchloroamide gives a compound identical with that obtained from toluene-*p*-sulphonyl chloride and triphenylphosphinephenylimine. 2 : 4-*Dichlorophenyl azide* (obtained by the action of sodium nitrite and hydrochloric acid on 2 : 4-*dichlorophenylhydrazine hydrochloride*, white needles, m. p. 205—208° [decomp.]), forms yellow needles, m. p. 51°, and is explosive when dry. With triphenylphosphine in ethereal solution it affords *triphenylphosphine*-2 : 4-*dichlorophenylimine*, $PPh_3{:}N\cdot C_6H_3Cl_2$, white tablets, m. p. 161°. The last substance is not basic and does not give an additive compound with toluene-*p*-sulphonyl chloride Triphenylphosphine and *p*-toluenesulphone-2 : 4-dichlorophenylchloroamide give an unstable additive *compound*. Various methods for the *N*-chlorination of anilides are studied. G. W. R.

Intensely Coloured Sodium Triphenylboryl, a remarkable Analogue of Sodium Triphenylmethyl. E. Krause (*Ber.*, 1924, **57**, [*B*], 216—217).—A preliminary communication. Ethereal solutions of boron triphenyl (Krause and Nitsche, A., 1922, i, 694) become intensely coloured in the presence of sodium wire and ultimately deposit orange-yellow, prismatic crystals. The coloured solutions are immediately decolorised by oxygen. H. W.

Organo-chromium Compounds. IV. Chromium Tetraphenyl Hydroxide. F. HEIN and O. SCHWARTZKOPFF (*Ber.*, 1924, **57**, [*B*], 8—14; cf. A., 1921, i, 826; 1922, i, 76, 77).—*Chromium tetraphenyl hydroxide*, $CrPh_4{\cdot}OH,3H_2O$, is prepared by the action of silver oxide on chromium tetraphenyl iodide dissolved in moist chloroform or methyl alcohol, or by the electrolysis of a solution of the iodide in alcohol with a platinum or mercury cathode and rotating silver anode. It crystallises in orange leaflets, m. p. 104—105°, and resembles closely the corresponding pentaphenyl derivative. Measurements of its electrolytic conductivity in aqueous solution show that it is comparable with the alkali hydroxides in strength, whilst comparative experiments in methyl-alcoholic solution show it to be a stronger base than chromium pentaphenyl hydroxide. The base is converted into the corresponding iodide, bromide, and chloride, and into chromium tetraphenylchromitetrathiocyanatodiammine, $Ph_4Cr\left[Cr\genfrac{}{}{0pt}{}{(CNS)_4}{(NH_3)_2}\right]$, which are identical with the compounds obtained previously (with elimination of a phenyl group) from chromium pentaphenyl hydroxide (cf. A., 1922, i, 76). *Chromium tetraphenyl hydrogen carbonate*, $CrPh_4{\cdot}HCO_3,2H_2O$, forms orange crystals, m. p. 110—111°. *Chromium tetraphenyl dianthranilate*, $NH_2{\cdot}C_6H_4{\cdot}CO_2CrH{\cdot}Ph_4$, orange needles, m. p. 145—146°, and the *salt*,

$$NH_2{\cdot}C_6H_4{\cdot}CO_2CrHPh_4,NH_2{\cdot}C_6H_4{\cdot}CO_2H,$$

m. p. 130°, are also described. H. W.

Structure of Proteins. E. ABDERHALDEN and W. STIX (*Z. physiol. Chem.*, 1923, **132**, 238—250).—With the view of differentiating between dipeptides and the corresponding diketopiperazines the formyl and acetyl derivatives of these compounds have been investigated. *Diformylglycine anhydride* crystallises in rosettes, m. p. 112° (not sharp). A formyl derivative of leucylglycine anhydride could not be prepared. Diacetylglycine anhydride was obtained crystalline (cf. Franchimont and Friedmann, A., 1908, i, 509), also *diacetylglycylalanine anhydride* (m. p. 47°, not sharp) but the *acetyl* derivative of *leucylglycine anhydride* could be obtained only as a syrup. *Diacetyl-leucylglycine* was obtained as a yellow powder (m. p. 95°) by the action of acetyl chloride on the dipeptide. An attempt to prepare bisulphite derivatives of glycine anhydride and silk peptone was unsuccessful. By the reduction of glycine anhydride, alanylglycine anhydride, and leucylglycine anhydride with metallic sodium in ethyl or amyl alcohol, small yields of the corresponding piperazines were obtained. *Dibenzoylmethylpiperazine*, $C_5H_{10}N_2Bz_2$ (crystallising in small plates), and *methylpiperazine dihydrochloride* were prepared from methylpiperazine obtained by reduction of alanylglycine anhydride. The reduction of diacetylglycine anhydride, diacetylglycylalanine anhydride, and diacetyl-*dl*-leucylglycine anhydride yielded piperazines, whilst from *dl*-leucylglycine and glycyl-*d*-alanine subjected to the same reaction the unchanged compounds were obtained. On applying the method to silk peptone, a mixture of piperazines was obtained yielding crystalline picrates and platinum salts, but these were not further characterised. It is hoped to extend the method to decide whether or not diketopiperazines are present as such in the protein molecule. J. P.

Effect of Ultra-violet Rays on Protein Solutions. R. MOND (*Pflüger's Archiv*, 1923, **200**, 374—378; from *Chem. Zentr.*, 1924, i, 69; cf. A., 1923, i, 868).—Solutions of crystalline egg-albumin or serum-albumin having p_H greater than 4·6 are rendered more acid by ultra-violet radiation, whilst solutions with p_H less than 4·3 are rendered more alkaline. The acidity of suspensions of lecithin is appreciably increased. Sera subjected to radiation have no hæmolytic effect and no effect on an isolated frog's heart. It is supposed that radiation causes the development in sera of substances which exert a dilatory effect on the vascular system. G. W. R.

New Sulphur-containing Amino-acid Isolated from the Hydrolytic Products of Protein. II. Sulphur Excretion after Ingestion. J. H. MUELLER (*J. Biol. Chem.*, 1923, **58**, 373—375).—When the amino-acid $C_5H_{11}O_2NS$ (cf. A., 1923, i, 869) is ingested by man, the sulphur which it contains is excreted in the urine in the form of inorganic sulphate. This is further evidence in favour of the view that the compound is a primary cleavage product of proteins. E. S.

Lysolecithins and Lysocephalins. II. Isolation and Properties of Lysolecithins and Lysocephalins. P. A. LEVENE, I. P. ROLF, and H. S. SIMMS (*J. Biol. Chem.*, 1924, **58**, 859—871; cf. A., 1923, i, 650).—The mixture of lysocephalin and lysolecithin, resulting from the action of cobra venom on egg yolk, has been separated by fractional crystallisation from chloroform and ether after precipitation with cadmium chloride. Lysocephalin has m. p. 198° (decomp.) and $[\alpha]_D^{35}+2{\cdot}0°$ in glacial acetic acid; lysolecithin, which is much more soluble in solvents, softens at about 100°, decomposes at 263°, and has $[\alpha]_D^{20}-2{\cdot}6°$ in chloroform, and $[\alpha]_D^{35}+0{\cdot}8°$ in glacial acetic acid. Hydrolysis yielded palmitic and stearic acids, whereas lysocephalin only yielded stearic acid. Dissociation constants were found, for lysolecithin $K_1=0{\cdot}18$, $K_2=1{\cdot}3\times10^{-12}$, and the isoelectric range p_H 2·75—9·90; for lysocephalin $K_1=3\times10^{-4}$, $K_2=3{\cdot}4\times10^{-10}$ and isoelectric range p_H 5·5—7·5. The question as to which of these constants is the acid and which the basic one is discussed. The hæmolytic activity of lysolecithin was found to be three times that of lysocephalin. G. M. B.

The Carbohydrate Group of Thymonucleic Acid. H. STEUDEL and E. PEISER (*Z. physiol. Chem.*, 1924, **132**, 297—300).—Thymonucleic acid on being hydrolysed and steam distilled yields a distillate which gives a red fuchsin-sulphite reaction, a green coloration with pine shavings, a red coloration with aniline acetate, and with orcinol–hydrochloric acid an intense reddish-violet product soluble in amyl alcohol. The ethereal extract of the hydrolysate gives the same reactions. The reactions formerly regarded as being those of a glucal-like residue are therefore ascribed to a volatile, ether-soluble substance which is regarded as furfuraldehyde. No definite conclusions are drawn as to the nature of the sugar residue responsible for the furfuraldehyde reactions. J. P.

Biochemistry.

Carbon Dioxide Absorption Curve of Human Blood. IV. Relation of the Hæmoglobin Content of Blood to the Form of the Carbon Dioxide Absorption Curve. V. The Construction of the CO_2 Absorption Curve from One Observed Point. VI. The Relationship of the CO_2 of Blood to that of Plasma. J. P. Peters, H. A. Bulger, and A. J. Eisenman (*J. Biol. Chem.*, 1924, **58**, 747—768, 769—771, 773—791).—IV. From a number of determinations of the carbon dioxide content of blood and its "true" plasma at various values of P_{CO_2} (*ibid.*, 1923, **55**, 687, 709), the relation of the hæmoglobin content of human blood to the slope of the absorption curve has been studied. The assumption (Van Slyke, Hastings, and Neill, A., 1923, i, 163) that values of individual buffers occurring in a complex system such as blood, when measured by the ratio $\Delta[MHCO_3]/\Delta P_H$ (Van Slyke, A., 1922, i, 893), can be considered as simple additive functions is shown to be unwarranted. Under the restricted conditions of the experiments recorded, the simple difference in the values of blood carbon dioxide content at P_{CO_2} 60 and 30 mm. (written $\Delta[CO_2]_{60-30}$) is a satisfactory and practical measure of buffer. From the scanty data available it seems possible that the buffer values of individual constituents, or at least the two main phases of the blood, when estimated as $\Delta[CO_2]_{60-30}$, may be considered as simple additive functions.

V. The determinants of the slope of the carbon dioxide absorption curve, other than the hæmoglobin concentration, have not yet been completely ascertained, but a method of calculation is now given which allows for this factor. In the relation $\Delta[CO_2]_{60-30}=0{\cdot}334 \times$ (oxygen capacity)$+6{\cdot}3$, cell volume may be substituted for oxygen capacity by means of the further equation: (oxygen capacity)$=$ 0·464 (cell volume) where both are expressed in vols. %. By the use of these relations, together with the graphic logarithmic method previously described (A., 1923, i, 1249), it is possible to construct the absorption curve from any single point. The average deviation of $\Delta[CO_2]_{60-30}$ from the mean in the experiments recorded is 0·5 vol.%

VI. Determinations are recorded of oxygen capacity (h), cell volume, and carbon dioxide content of whole blood $[CO_2]_b$, and of the carbon dioxide content $[CO_2]_p$ of the plasma at $P_{CO_2}=40$ mm. on a number of specimens of blood, and on others at $P_{CO_2}=30$ and 60 mm. The relation $[CO_2]_p=[CO_2]_b+(0{\cdot}0159[CO_2]_b-0{\cdot}281)h$ is found to hold when $P_{CO_2}=40$ mm. and allows of the calculation of the carbon dioxide content of plasma from that of whole blood. For tensions other than 40 mm., a slightly modified relation is used. G. M. B.

Rates of Reduction and Oxidation of Blood. A. E. KOEHLER (*J. Biol. Chem.*, 1924, **58**, 813—830).—The rate of oxidation and reduction of blood was followed by comparison with fully oxygenated blood in a colorimeter so designed as to allow of rotation of the specimen in a stream of gas. The velocity of the reactions was found to be largely affected by the oxygen tension. An increase of p_H increases the rate of oxidation and depresses the rate of reduction, whilst a decrease of p_H has the opposite effects. The influence of carbon dioxide or lactic acid on the velocities is in accordance with the changes of p_H produced, there being no specific action of carbon dioxide. Certain ions such as $Na^\cdot$ modify the oxidation and reduction curves considerably. G. M. B.

Cholesterol and Bicarbonate Content of Blood in Experimental Kidney Diseases. A. STASIEK (*Biochem. Z.*, 1924, **144**, 477—481).—Hypercholesterinæmia can be produced in dogs by inducing kidney disease by such drugs as cantharidine, uranium nitrate, and mercuric chloride. As the animals were fed during the experimental period on diets free from fat and cholesterol it may be assumed that the hypercholesterinæmia is of endogenous origin. Acidosis is not responsible for this metabolic derangement, since the bicarbonate content of the blood remains normal until after the manifestation of the hypercholesterinæmia. It is suggested that this condition is produced, not only because of the damage done to the cells of the kidney by the above agents, but also by the effect of these agents on the lipoids in other parts of the body. S. S. Z.

Amino-acid Content of the Blood in Normal and Pathological Conditions. C. H. GREENE, K. SANDIFORD, and H. ROSS (*J. Biol. Chem.*, 1924, **58**, 845—857).—The amino-nitrogen content of blood as determined by the Folin method (which was found to be trustworthy in presence of an excess of urea) in cases of twenty different pathological conditions was similar to that in the blood of normal persons, namely, between 4·8 and 7·8 mg. per 100 c.c., with an average of 6·3 mg. The level of amino-nitrogen may be increased by flooding the organism with amino-acids during digestion or from the rapid autolysis of body-tissue, but otherwise deviation beyond the limits mentioned is rare. G. M. B.

Effect of Adrenaline on the Composition of Blood under Normal Conditions in Fasting, and in Avitaminosis. D. ALPERN and J. A. COLLAZO (*Z. ges. exp. Med.*, 1923, **35**, 288—295; from *Chem. Zentr.*, 1924, i, 67—68).—Residual nitrogen, urea, sugar, and amino-acids in the blood of fasting dogs were found to be scarcely above normal. Values appreciably above the normal were obtained with a diet poor in vitamins. The total ethereal extract of blood was depressed in fasting, but increased by a diet low in vitamins. Adrenaline hyperglycæmia was less marked with low-vitamin diet than in fasting. This was the case even with a triple dose of adrenaline. In the case of fasting and normally-fed animals, the administration of adrenaline resulted in a decrease in the total ether extract and the total ethyl alcohol extract of the blood. With a diet poor in vitamins, on the other hand, increases in these values were observed. The adrenaline effect is related to the diminished power of oxidation and assimilation in the body-cells in avitaminosis. G. W. R.

Formation of Methæmoglobin. W. Lipschitz and J. Weber (*Z. physiol. Chem.*, 1924, **132**, 251—274).—The influence of various aromatic and other compounds in converting the blood pigment into methæmoglobin has been investigated. β-Phenylhydroxylamine, hydrazobenzene, and arsenic hydride form methæmoglobin only in the presence of oxygen and have no action on reduced hæmoglobin. Dimethylaminophenyl ether, azo- and azoxy-benzene, and *p*-hydroxyazobenzene are without effect on hæmoglobin. Benzoquinone and its oximes are decreasingly active in forming methæmoglobin in the order given, but quinonechlorimine is five times as active as quinone. Hæmoglobin at 20° brings about a catalytic decomposition of hydroxylamine into nitrogen and ammonia which reaches a maximum when the reactants are present in the proportion 2 mols. of hydroxylamine : 1 mol. of hæmoglobin. Methæmoglobin catalyses the same reaction. Whilst hydroxylamine and α-methylhydroxylamine convert both oxyhæmoglobin and reduced hæmoglobin into methæmoglobin, β-phenylhydroxylamine acts on oxyhæmoglobin only, and when present in excess converts methæmoglobin into reduced hæmoglobin. By treating reduced hæmoglobin with arsenic hydride followed by a little oxygen a, pigment is obtained with a band at 608—625 $\mu\mu$, which on further treatment with oxygen yields methæmoglobin. This is in agreement with the "nitrobenzenehæmoglobin" described by Filehne (*Arch. exper. Path.*, 1878, **9**, 329), and the latter supposed pigment is therefore regarded as unspecific. J. P.

Formation of Porphyrin from Blood Pigment. I. Spectroscopic Properties of Porphyrin Esters. O. Schumm (*Z. physiol. Chem.*, 1924, **132**, 34—61).—By treatment of hæmoglobin free from oxygen, from blood corpuscles, with 25% hydrochloric acid, a porphyrin is formed. The same porphyrin is formed along with hæmatin if fuming hydrochloric acid is used. If, however, the hæmoglobin is treated with 1·3—2·6% of alcoholic hydrogen chloride, in the presence or in the absence of air, no formation of porphyrin occurs. A porphyrin, obtained from hæmatin by treatment with hydrazine hydrate, possesses properties and spectrum similar to those of the porphyrin obtained from hæmoglobin by the action of hydrochloric acid, but it has not been proved that they are identical. The spectroscopic properties of the methyl esters of urinoporphyrin

(Fischer), cotporphyrin, and of Nenki's hæmatoporphyrin are described. W. O. K.

Blood Pigment of *Arenicola*. J. Barcroft and H. Barcroft (*Proc. Roy. Soc.*, 1924, **B**, **96**, 28—42).—The blood pigment of *Arenicola* differs from human hæmoglobin in the following facts: (1) the α-absorption bands of the oxy and carboxy compounds are displaced towards the violet end of the spectrum; (2) its affinity for oxygen is much greater, so that gaseous exchange can take place at pressures of oxygen between 2 and 3 mm.; (3) carbon monoxide has only 70 times the affinity for *Arenicola* hæmoglobin that oxygen has (as compared with 250 times for human hæmoglobin). The function of the pigment is probably to act as a reserve store of oxygen for those periods during which the animal has not access to sea-water. C. R. H.

Inorganic Bases and Phosphates in Relation to the Protein of Blood and other Body Fluids in Bright's Disease and in Heart Failure. H. A. Salvesen and G. C. Linder (*J. Biol. Chem.*, 1923, **58**, 617—634).—Determinations have been made of the content of certain inorganic constituents (bases and phosphates) and of proteins in the blood plasma of patients suffering from Bright's disease. In the absence of uræmia, the content of calcium and of protein was found to run parallel. In uræmic cases, however, this parallelism was absent, a marked fall in the calcium content occurring with a protein content only slightly below normal; this effect is attributed to a great retention of phosphates in these cases.

From analyses of blood plasma and other body fluids in cases of heart failure, it appears that 55—70% of the serum calcium is diffusible. The non-diffusible calcium is probably bound to proteins. E. S.

Action of Peptone and of Nucleic Acids on the Coagulability of the Blood. J. W. Pickering and J. A. Hewitt (*Proc. Roy. Soc.*, 1924, **B**, **96**, 77—94).—Intravascular injection of Witte's peptone inhibits coagulation of the blood in tortoises which have been deprived of hepatic activity, and, to a variable extent, in rats and dogs. Addition of peptone to shed blood delays its coagulation if the blood has not been in contact with damaged tissue. Such blood contains fibrinogen, and will clot on dilution with water or on prolonged exposure to air. Similar results are obtained with nucleic acids derived from thymus and yeast. In all cases the anticoagulant effect is antagonised by the presence of increased amounts of carbon dioxide in the circulating blood; animals can be immunised against the nucleic acid effect by serial intravascular injections of protein-free nucleic acid preparations. C. R. H.

Equilibria involving Calcium, Hydrogen, Carbonate, Bicarbonate, and Phosphate Ions. I. N. Kugelmass and A. T. Shohl.—(See ii, 235.)

Physico-chemical Basis of Vital Permeability. IV. R. Brinkman and A. von Szent-Györgi.—(See ii, 235.)

Relation between Calcium and Protein of Serum in Tetany due to Parathyroidectomy. H. A. Salvesen and G. C. Linder (*J. Biol. Chem.*, 1923, **58**, 635—639).—The decrease in serum calcium in parathyroidectomised dogs is not accompanied by a decrease in plasma protein. Apparently, a parallelism between the decrease in calcium and protein (cf. preceding abstract) indicates a decrease in protein-bound calcium and does not lead to tetany, whereas a decrease in calcium without a corresponding decrease in protein (as in parathyroidectomy) indicates, primarily, a decrease in ionised calcium, which leads to tetany. E. S.

Mechanism of Syphilitic Serological Reactions. The Protein Fractions of Human Blood Serum. R. Stern (*Biochem. Z.*, 1924, **144**, 115—137).—A study has been made of the protein fractions of syphilitic and non-syphilitic sera. The so-called euglobulin fraction, comprising a small part of the water-insoluble globulin, has no significance for the typical serological reactions in syphilitic conditions. This is called " Labileglobulin." The separation from sera of a true euglobulin is described and this on peptisation in " Normosal " (Sächsischen Serumwerke) gives positive or negative Wassermann and Sachs-Georgi reactions according to the reaction of the original serum. The residual serum after removal of the euglobulin gives uniformly negative results, whether separated into its fractions or otherwise. The electrical charge of the euglobulin responsible for the specific reactions bears no relation to the positive or negative nature of the tests. Tannin solutions may convert negative into positive sera, and may themselves react positive to the Wassermann and Sachs-Georgi tests. It is tentatively suggested that the specific action of the euglobulin is due to dehydration in accord with the action of tannin in sensitising dyestuff sols. J. P.

Physiology of Digestion. I. The Diastatic Power of the Mixed Saliva of Man, the Horse, Ox, Pig, and Dog, with Observations on the Complex Nature of Salivary Diastase. II. Fluctuations in the Diastatic Power of Mixed Saliva. C. Schwarz and K. Steinmetzer (*Fermentforsch.*, 1924, **7**, 229—253).—I. For man the mean diastatic power (D) found was 1600, for the pig only 14. The saliva of the other animals contained no amylase. Amylase exists in the human salivary glands as an inactive proferment which becomes active upon secretion under the influence of the salts (possibly sodium chloride) of the saliva. II. The diastatic power of human saliva becomes constant in the fasting state. R. K. C.

Physiology of Digestion. X. The Effect of Kristallose, Saccharin, and Parasaccharin on Salivary Diastase. C. Schwarz and E. Buchlman (*Fermentforsch.*, 1924, **7**, 282—300). **XI. The Effect of Kristallose, Saccharin, and Parasaccharin on Peptic and Tryptic Digestion.** C. Schwarz and V. Zellinger (*ibid.*, 301—306).—X. These substances have no effect on salivary diastase in concentrations up to 1%. Earlier results to the contrary are due to failure to control the p_H of the tests. XI. In concentrations such as might be taken by man, these are without effect on protein digestion by pepsin or trypsin. ("Kristallose" is the sodium salt of saccharin.) R. K. C.

Physiology of Digestion. VIII. Digestion in the Crop of the Fowl. C. SCHWARZ and H. TELLER (*Fermentforsch.*, 1924, **7**, 254—269).—The secretion of the crop is a yellow, viscid fluid generally acid to litmus but devoid of amylolytic or proteolytic activity. Lactic acid is generally to be found in the crop contents, but free hydrochloric acid is absent. Food remains many hours in the crop whilst it undergoes swelling (and some autofermentation) preparatory to digestion elsewhere. No absorption of water, salt, or dextrose by the mucous membrane of the crop was detected. R. K. C.

Absorption of Lecithin. F. EICHHOLTZ (*Biochem. Z.*, 1924, **144**, 66—69).—Lecithin (Witte) fed to young dogs produced an increase in the alcohol-ether-soluble organic phosphorus compounds of the blood, but had no effect on the total fat. It is concluded that lecithin is assimilated as such and that its fatty acid residue is not built up into neutral fats. J. P.

Digestion Experiments with the Raw White of Egg. II. The Digestibility of Unbeaten in Comparison with Beaten Whites. M. S. ROSE and G. MACLEOD (*J. Biol. Chem.*, 1923, **58**, 369—371; cf. *ibid.*, 1922, **50**, 83).—In general, the digestion of beaten egg whites is somewhat more complete than that of unbeaten. The average coefficient of digestibility obtained for raw white of egg is 83%, and for cooked white of egg 86%. E. S.

Effect of Reaction Changes upon Human Carbohydrate and Oxygen Metabolism. J. B. S. HALDANE, V. B. WIGGLESWORTH, and C. E. WOODROW (*Proc. Roy. Soc.*, 1924, **B**, **96**, 15—28).—In the alkalosis produced by forced breathing or by ingestion of sodium bicarbonate the preliminary activation of glucose, which is necessary before it can be metabolised, is inhibited, with resulting acetonuria, and hyperglycæmia and glycosuria after less than half the normally tolerated dose of glucose.

The acidosis caused by breathing carbon dioxide has no effect on carbohydrate metabolism; after ingestion of ammonium chloride there is observed a lowering of sugar tolerance in the post-acidotic stage which is probably due to a failure of the glycogenic function of the liver.

Ingestion of sodium hydrogen carbonate causes an increase in the consumption of oxygen, the reverse effect being produced by ammonium chloride. C. R. H.

Clinical Calorimetry. XXXIV. Ketosis and the Respiratory Exchange in Diabetes. H. B. RICHARDSON and W. S. LADD (*J. Biol. Chem.*, 1924, **58**, 931—968).—The fatty acid : glucose ratio, calculated from the data obtained by the calorimetric method previously described (Richardson and Mason, *ibid.*, 1923, **57**, 587), was found to be parallel to the excretion of acetone compounds. The threshold of ketosis was found at a ratio of about 1·5 to 1, which corresponds with the presence, during oxidation, of 1 mol. of keto-acid for every mol. of glucose. This parallelism is evidence that the respiratory quotient in diabetes is a true measure of oxidation. Diabetic patients were often able to take diets containing a larger proportion of ketogenic substances than is called for by the above-mentioned molecular ratio, which indicates that the proportions of foodstuffs oxidised were not the same as those ingested.

The fall of ketosis observed in diabetic patients, when fasting, is accounted for by the simultaneous drop in the fatty acid : glucose ratio calculated from the calorimetric data. It was due primarily to a decrease in the total metabolism with a consequent diminution in the metabolism of fat and protein.

During fasting there was little or no increase in the total quantity of glucose oxidised when this was computed as being derived from protein and the glycerol of the fat, as well as from the carbohydrate, undergoing metabolism. Fasting reduces the blood-sugar chiefly by depleting the endogenous sources of glucose. There is often an increase in the oxidation of glucose during the subsequent period of restricted diet, but this is not necessarily due to the fast.

G. M. B.

Acetonæmia, especially in Avitaminosis. M. Händel (*Biochem. Z.*, 1924, **144**, 258—264).—Using a micro method based on that of Bang, the acetone content of the blood of normal, starving, phloridzinised, depancreatised, and avitaminosed dogs, and of normal ox and human blood, has been determined. Avitaminosis leads to no increase in the acetone compounds of dog's blood. Normal human blood contains only traces of free acetone, 2 to 4 mg.% as acetoacetic acid, and 3 to 5 mg.% as β-hydroxybutyric acid. Acetonæmia is most marked in depancreatised dogs and in dogs which have been simultaneously starved and phloridzinised. J. P.

Carbohydrate Metabolism. XXI. The Relation of Sugar Excretion to Renal Integrity. F. P. Underhill and G. Wilens (*J. Biol. Chem.*, 1923, **58**, 153—162).—Following experimental tartrate nephritis, the renal threshold for dextrose appears to be alternately raised and lowered. An injection of dextrose increases the hyperglycæmia. E. S.

Physiological Behaviour of Glucosan. J. Kerb. **Glucosan.** J. Kerb and E. Kerb-Etzdorf (*Biochem. Z.*, 1924, **144**, 60—63).—Arising from Grafe's treatment of diabetes with caramel (*Deutsch. Arch. f. klin. Med.*, 1914, **116**, 437) the physiological action of α-glucosan, *l*-glucosan, and lævulosan is under investigation. The administration of α-glucosan to diabetics and to depancreatised dogs does not produce a rise in blood-sugar. In one case of severe diabetes a slight decrease lasting for one hour was observed. J. P.

Some Changes in the Composition of Blood due to the Injection of Insulin. A. P. Briggs, I. Koechig, E. A. Doisy, and C. J. Weber (*J. Biol. Chem.*, 1924, **58**, 721—729).—A series of analyses of the blood of dogs after injection of insulin, show that the concentrations of glucose, inorganic phosphate, and potassium in the blood are thereby decreased. A parallel increase observed in the concentration of lactic acid present, is believed to be due to the influence of insulin on the reversible reaction : glucose $\rightleftharpoons$ lactic acid. G. M. B.

Insulin and Phloridzin Diabetes. T. P. NASH, jun. (*J. Biol. Chem.*, 1923, **58**, 453—462).—The results reported are of a preliminary nature and appear to indicate that the administration of insulin to a phloridzinised dog does not cause a utilisation of sugar. E. S.

Influence of Insulin on Phloridzin Diabetes. M. RINGER (*J. Biol. Chem.*, 1923, **58**, 483—501).—Injection of insulin into completely phloridzinised dogs causes the oxidation of dextrose. At the same time, deposition of dextrose as glycogen takes place, the protein metabolism and the heat production are reduced, and the excretion of ketonic substances ceases. These results indicate that the effect of phloridzin is due to a transitory injury to the pancreas. It is suggested that, using phloridzinised dogs, insulin might be assayed in terms of the utilisation of dextrose. The maximum utilisation (oxidation) obtained in the present experiments was 0·95 g. of dextrose per unit of insulin. E. S.

Effect of Alcoholic Pancreas Extract (Insulin) on the Behaviour of the Kidneys towards Dextrose. S. VAN CREVELD and E. VAN DAM (*Nederl. Tijdschr. Geneeskunde*, 1923, **67**, II, 1498—1510; from *Chem. Zentr.*, 1924, i, 215).—From experiments on the perfusion of frog kidneys with dextrose solutions after administration of insulin it is concluded that the specific substance of insulin has a direct effect on the kidneys. G. W. R.

What Substance in the Carbohydrate Metabolism is acted on by Insulin? E. TOENNIESSEN (*Z. physiol. Chem.*, 1924, **133**, 158—164).—The author maintains that insulin acts on the lactic acid formed in the metabolism of carbohydrates in the animal organism, since all the previous stages in this metabolic process proceed normally in the absence of the pancreas. He was able to demonstrate that on adding lactic acid to minced pancreas there is no increase in the formation of acetaldehyde, but in the presence of pancreas and minced muscle the amount of acetaldehyde formed was double that formed by the control organs alone. Acetaldehyde was also formed on introducing insulin into normal and more so into diabetic blood. It is supposed to be derived from lactic acid. S. S. Z.

Comparative Study of the Blood-sugar Concentration in the Liver Vein, the Leg Artery, and the Leg Vein during Insulin Action. C. F. CORI, G. T. CORI, and H. L. GOLTZ (*J. Pharm. Exp. Ther.*, 1923, **22**, 355—373).—Determinations of the blood-sugar show that in the rabbit, starved for twenty-four hours, the concentration in the liver vein is on the average 28 mg.% higher than in the neck vein, and 23 mg.% higher than in the femoral artery, whilst that in the femoral artery is 8 mg.% higher than that in the femoral vein. Under the influence of insulin, the first two figures tend to decrease and the last one to increase, so that there would appear to be diminished output of sugar by the liver, and increased uptake by the muscles. W. O. K.

Physiological Action of Insulin. U. Sammartino and D. Liotta (*Arch. Farm. Sperim.*, 1924, **23**, 13—46).—The authors discuss the question of glycæmia in relation to the action of insulin. The blood-sugar content of fasting rabbits following the injection of a unit dose of insulin falls below 0·045 mg.%, and is accompanied by hypoglycæmic convulsions and death. Even after death has been prevented by intravenous injection of dextrose (1 g. per kg. body weight), hypoglycæmia persists for 3—5 days. After repeated unit doses, recovery through injection of sugar is no longer possible. Administration of sucrose, or of dextrose in amount less than 1 g. per kg. body weight, does not prevent death from hypoglycæmia. Insulin also produces a fall in glycæmia in hyperglycæmia produced by adrenaline or lesion of the fourth ventricle. Hypoglycæmic coma and death are not prevented by administration of vaso-constrictive substances, such as ergotine and pituitary extract. Injection of insulin produces a lowering of blood pressure which cannot be neutralised by intravenous injection of sugar. G. W. R.

Glucokinin. III. An Apparent Synthesis in the Normal Animal of a Hypoglycæmia-producing Principle. Animal Passage of the Principle. J. B. Collip (*J. Biol. Chem.*, 1923, **58**, 163—208).—The marked hypoglycæmia and other symptoms which are produced in normal rabbits by the injection of glucokinin (A., 1923, i, 1247) have also been observed after injection of guanidine sulphate or of overdoses of insulin, and after prolonged fasting; hypoglycæmia also occasionally occurs spontaneously, in which case *Coccidia oviforme* have been found in the liver. Transitory relief of the symptoms may be effected by injection of dextrose, but the death of the animal ultimately results. When defibrinated blood or serum from such hypoglycæmic rabbits is injected into normal rabbits, similar symptoms occur, animal passage (rabbit) of the hypoglycæmia-producing principle apparently being capable of indefinite extension. The principle is thermostable, undergoes dialysis, and is precipitated from blood by ammonium sulphate, but not by tungstic acid. E. S.

Aqueous Extracts of Pancreas. II. Physical and Chemical Behaviour of Insulin. H. A. Piper, R. S. Allen, and J. R. Murlin (*J. Biol. Chem.*, 1923, **58**, 321—336).—Observations which have been made during the preparation of insulin lead to the conclusion that insulin is not a protein; it appears, however, to exist in the pancreas in combination with protein. The purest preparations of insulin are fairly stable and may be stored for 4 months without loss of potency; solutions may be heated at 80° for half an hour without marked destruction. Insulin does not diffuse readily through parchment membranes; it is adsorbed by charcoal from acid but not from neutral solution.

E. S.

Aqueous Extracts of Pancreas. III. Some Precipitation Reactions of Insulin. C. P. Kimball and J. R. Murlin (*J. Biol. Chem.*, 1923, 58, 337—346).—In developing a method for the preparation of insulin from aqueous extracts of pancreas a large number of both organic and inorganic precipitants have been tested, but the majority have been rejected owing to the difficulty of removing them from the precipitate. Among the more successful precipitants are amyl alcohol and sodium chloride. The former is used in conjunction with ethyl alcohol. Four to five volumes of ethyl alcohol are added to the aqueous extract; the addition of amyl alcohol then causes the insulin to separate as a solid layer between the aqueous and the alcoholic layers. Acetone also precipitates the insulin but it has the disadvantage that it precipitates at the same time a substance, to which the name *glucagon* is given, which produces a distinct hyperglycæmic effect in animals; it may be removed from the precipitated insulin by extraction with 95% alcohol. Saturation of an aqueous extract with sodium chloride causes complete precipitation of the insulin. Sodium chloride has the advantage over ammonium sulphate that traces of it are not harmful to the organism, whereas the ammonium sulphate, if not completely removed from the precipitate, may cause a hyperglycæmic reaction.

E. S.

Action of Ammonium Hydroxide and other Alkaline Compounds on Insulin. E. J. Witzemann and L. Livshis (*J. Biol. Chem.*, 1923, 58, 463—474).—Treatment of insulin with 0·5 or 0·7*N*-ammonia or with 0·1*N*-sodium or potassium hydroxide for some days causes complete inactivation. When ammonia has been employed, the activity may be quickly restored by acidification with hydrochloric acid; inactivation by sodium or potassium hydroxide, however, is irreversible. Sodium carbonate and hydrogen carbonate and disodium hydrogen phosphate have scarcely any action on the activity of insulin. When insulin is treated with mixed alkalis the inactivation may be either accelerated or retarded according to the mixture employed. The effect of ammonia is regarded as indicating a tautomeric change in the molecule.

E. S.

Chemical Reactions of the Substance containing Insulin. H. A. Shonle and J. H. Waldo (*J. Biol. Chem.*, 1924, 58, 731—736).—A detailed chemical examination of an insulin preparation from the pancreas of hogs. Precipitation and other methods of purification failed to separate a physiologically active substance of constant ultimate composition. The preparation appeared to be a complex mixture of proteoses, and the active principle itself may either be a proteose or be intimately associated with a proteose fraction.

G. M. B.

Adrenaline Secretion in Adrenaline Glycæmia. P. Trendelenburg (*Pflüger's Archiv*, 1923, **201**, 39—55; from *Chem. Zentr.*, 1924, i, 212).—Decomposition of glycogen results from the administration of smaller amounts of adrenaline than has been previously supposed. Blood-sugar in rabbits was increased by continuous administration of 0·00006—0·0001 mg. of adrenaline per kg. live weight per minute. Glycosuria does not appear unless larger doses are given. The secretion of adrenaline by the suprarenal bodies after the production of adrenaline hyperglycæmia was found to be more than 0·0005 mg. per kg. live weight per minute, a rate of production sufficient to cause glycosuria within a short time. There is probably a direct nervous stimulation of the liver cells in addition to the chemical effect. G. W. R.

Carbohydrate Metabolism of *Ascaris Megalocephala*. A. Fischer (*Biochem. Z.*, 1924, **144**, 224—228).—In view of the fact that the acid formation in autolysis of *Ascaris megalocephala* is accounted for by the breakdown of glycogen to lactic acid and carbon dioxide, doubt is expressed regarding the conclusions of Weinland (*Z. Biol.*, **42**, **43**), who regarded the acidity as being due to valeric acid, and the carbohydrate metabolism of these worms as being abnormal. J. P.

Fat Metabolism in Avitaminosis. V. Distribution of Fats and Lipoids in the Liver after Phosphorus Poisoning in Normal, Starving, and Avitaminosed Animals. K. Asada (*Biochem. Z.*, 1924, **144**, 203—211).—A histological study of the distribution of neutral fat in the livers of normal, starved, and avitaminosed rats confirms the author's earlier observations (A., 1924, i, 122, 245), but as regards lipoids, the microscopical appearance of the phosphorus-poisoned avitaminosed liver is the same as that of the poisoned normal liver despite the increased cholesterol content of the former as revealed by chemical methods. The conclusions of Salvioli and Sacchetto (*Frankf. Z. Path.*, 1922, **28**) regarding the effect of phosphorus poisoning on the fat and lipoid content of the livers of normal and starving dogs are based on too short periods of starvation. J. P.

Comparative Metabolism of certain Aromatic Acids. V. Fate of some Ring Substitution Products of Phenylacetic Acid in the Organisms of the Dog, Rabbit, and Man. L. R. Cerecedo and C. P. Sherwin (*J. Biol. Chem.*, 1923, **58**, 215—224).—When fed to human beings, dogs, or rabbits, *o*-nitrophenylacetic acid, *o*-aminophenylacetic acid, *o*-hydroxyphenylacetic acid, *o*-chlorophenylacetic acid, and 2 : 4-dinitrophenylacetic acid were excreted unchanged with the following exceptions: *o*-aminophenylacetic acid, which was excreted by rabbits in an acetylated form, and *o*-chlorophenylacetic acid, which was conjugated with glycine both in man and in the dog and excreted as *o*-chlorophenaceturic acid. All the above acids were less toxic than phenylacetic acid. The results show that *o*-compounds are not readily oxidised in the organism and that they are not necessarily more toxic than the *m*- and *p*-isomerides.

o-Chlorophenaceturic acid, m. p. 135°, has been synthesised from glycine and *o-chlorophenylacetyl chloride*, b. p. 119—121°/12 mm. The latter substance was obtained by the action of phosphorus pentachloride on *o*-chlorophenylacetic acid. E. S.

Detection of Pyruvic Acid in Muscle and Liver. L. J. SIMON and E. AUBEL (*Compt. rend.*, 1924, **178**, 657—659; cf. A., 1923, i, 875).—Pyruvic acid is not destroyed under aseptic conditions by macerated liver or fresh muscle. If injected as the sodium salt *in vivo* into the liver, it disappears, but not rapidly. Alanine, dextrose, and sodium lactate under similar conditions are not converted into detectable quantities of pyruvic acid. The latter, however, may possibly be produced in very small quantities, or undergo immediate conversion into other substances. E. E. T.

Specific Dynamic Action of Proteins. P. LIEBESNY (*Biochem. Z.*, 1924, **144**, 308—350).—The specific dynamic action of proteins, following the ingestion of 200 g. of flesh and 100 g. of bread, reveals itself in an increase of 20—40% above the oxygen consumption shown in the resting and fasting condition, the maximum increase occurring in from 1 to 2½ hours after the meal. For any one individual, the specific dynamic action is constant under like conditions over a period of some months. It is diminished or entirely lacking in cases of affection of the hypophysis and in conditions involving disturbance of the autonomic nervous system. Administration of preparations of the anterior lobe of the pituitary gland produces an increase in the specific dynamic action. J. P.

Adsorption of Amino-acids by Animal Tissues. W. MOELLER (*Biochem. Z.*, 1924, **144**, 152—158).—Hide powder adsorbs tyrosine from aqueous solution to the extent of 45% in 10 days. Importance is attached to the part played by such adsorption phenomena in the biosynthesis and hydrolysis of proteins. J. P.

Arginine Metabolism. K. FELIX and K. MORINAKA (*Z physiol. Chem.*, 1924, **132**, 152—166).—*dl*-Arginine, when passed through the liver of a cat, is hydrolysed fairly completely into ornithine and urea, both isomerides being attacked. Arginine, absorbed through the intestinal wall and then allowed to pass through the liver, is similarly hydrolysed by the liver. On the other hand, arginine in clupeon, which is built up of 2 mols. of arginine and 1 mol. of a monoamino-acid, is not hydrolysed by the liver. It would appear, therefore, that arginine, after absorption from the intestine, escapes complete destruction by the liver by being at least partly combined in the form of a polypeptide. W. O. K.

Animal Calorimetry. XXIII. Influence of the Metabolism of the Nucleic Acids on Heat Production. M. RINGER and D. RAPPORT (*J. Biol. Chem.*, 1923, **58**, 475—482).—It is concluded from experiments on dogs that nucleic acids exert no specific dynamic effect. E. S.

Metabolism of *l*-Pyrrolidonecarboxylic Acid and its Stability to Acids and Alkalis. R. M. BETHKE and H. STEENBOCK (*J. Biol. Chem.*, 1923, **58**, 105—115).—When fed in large amounts to pigs maintained on a starch diet, pyrrolidonecarboxylic acid is partly metabolised and partly excreted unchanged. No increase occurs in the amino-nitrogen content of the urine, thus indicating that the hydrolysis of the acid is not sufficiently rapid to lead to the production of glutamic acid in amounts greater than those which the organism can deaminise. The acidity and alkalinity of the alimentary canal are insufficient to account for the hydrolysis.
E. S.

Effects of Iodides on Nitrogen Metabolism. G. P. GRABFIELD, B. J. ALPERS, and A. M. PRENTISS (*J. Pharm. Exp. Ther.*, 1924, **22**, 393—400).—Administration of sodium or potassium iodides to man increases the output of nitrogen in the urine; the latter salt also increases the non-protein nitrogen of the blood.
W. O. K.

Effect of Reaction Changes on Human Inorganic Metabolism. J. B. S. HALDANE, V. B. WIGGLESWORTH, and C. E. WOODROW (*Proc. Roy. Soc.*, 1924, **B**, **96**, 1—14).—The alkalosis of forced breathing produces a fall in the inorganic phosphate of the blood accompanied by a fall in the excretion in the urine; the reverse effects are observed in the acidosis caused by the breathing of carbon dioxide. The ingestion of sodium bicarbonate produces no effect. In the acidosis following ingestion of ammonium chloride there is a heavy excretion of phosphate in the urine which falls off with the exhaustion of the available store of phosphate in the body, the immediate cause of the falling off being the low concentration of phosphate in the blood. Ammonium chloride acidosis also causes the body to lose large amounts of water, sodium, and potassium. C. R. H.

Acid–Base Metabolism. I. Determination of Base Balance. A. T. SHOHL and A. SATO (*J. Biol. Chem.*, 1923, **58**, 235—255).—Analyses have been made of the food, urine, and fæces of four male infants less than 1 year old. For purposes of calculating the acid–base balance, only sodium, potassium, calcium, magnesium, sulphates, phosphates, and chlorides are considered. Sulphur and phosphorus contained in the food are regarded as acidic constituents to the extent that they are oxidised in the organism to sulphates and phosphates. The results show that there is a normal positive base balance equivalent to 10 c.c. ± 2 c.c. of $0{\cdot}1N$ base per kg. per day. This balance is lowered by the addition of hydrochloric acid to the diet and raised by the addition of sodium hydrogen carbonate. The acid added to the food is excreted in the urine; the base, however, is excreted partly in the urine and partly in the fæces. E. S.

Acid–Base Metabolism. II. Mineral Metabolism. A. T. SHOHL and A. SATO (*J. Biol. Chem.*, 1923, **58**, 257—266).—Hydrochloric acid increases the excretion of ash, nitrogen, calcium, sodium, phosphorus, and chlorine in the urine of infants, and of ash, nitrogen, calcium, magnesium, and chlorine in the fæces, and decreases that of phosphorus in the fæces; the excretion of potassium, magnesium, and sulphur in the urine and of sodium and potassium in the fæces is unaffected. The net result is a decreased retention of ash, nitrogen, calcium, magnesium, sodium, potassium, phosphorus, sulphur, and chlorine. Sodium hydrogen carbonate increases the excretion of ash, nitrogen, sodium, potassium, sulphur, and chlorine in the urine, and of ash, nitrogen, calcium, sodium, potassium, phosphorus, sulphur, and chlorine in the fæces; it decreases the calcium, magnesium, and phosphorus in the urine, and the magnesium in the fæces. In this case, the net result is an increased retention of magnesium and sodium and a decreased retention of ash, nitrogen, calcium, potassium, phosphorus, sulphur, and chlorine. E. S.

Calcium Content of the Organs of Cats Treated with Calcium [Salts]. III and IV. H. Jungmann and M. Samter (*Biochem. Z.*, 1924, **144**, 265—269).—III. Determinations have been made of the distribution of calcium in the tissues of cats to which intravenous injections of calcium chloride and of calcium fructosephosphate had been given. After chloride administration the kidney showed a very high calcium content, and the lesser intestine, in contrast to that of normal animals, showed a uniform distribution of calcium along its entire length. Injection of calcium fructosephosphate, which has a more marked effect than has the chloride in increasing the calcium of the tissues generally, gave a notable increase in the calcium content of liver and kidney. IV. Intravenous injection of calcium chloride produces a greater increase in the calcium of the cat's kidney than does subcutaneous administration (cf. Heubner and Rona, A., 1923, i, 415). After intravenous injection of calcium fructosephosphate, the blood-serum and liver contain up to six times as much calcium as does the blood or liver of normal cats, or of cats given subcutaneous injections of calcium chloride. In acute calcium poisoning the calcium content of the skin may possibly be increased. Repeated injection of calcium acetate produces no alteration in the calcium content of the liver, heart, or other organs, nor does it affect the growth curves of the cats, as does subcutaneously administered calcium chloride (cf. Heubner and Rona, *loc. cit.*). J. P.

Metabolism of Inorganic Salts. IV. The Content of Inorganic Salts in the Blood in Pregnancy, with Especial Reference to Calcium. F. P. Underhill and Alice Dimick (*J. Biol. Chem.*, 1923, **58**, 133—140).—In general, little change occurs in the inorganic constituents of the blood during pregnancy, although the calcium content (determined on whole blood) is somewhat higher for pregnant than for non-pregnant women. The calcium content does not vary in a regular manner with the course of pregnancy. These results give no support to the view that an increased calcium content of the blood is of significance in the induction of labour. E. S.

Metabolism of Inorganic Salts. V. Inorganic Salt Metabolism in Cocaine Poisoning. F. P. UNDERHILL and E. G. GROSS (*J. Biol. Chem.*, 1923, **58**, 141—146).—No change is produced in the inorganic constituents of the blood by cocaine poisoning. The relief afforded by the administration of calcium salts is due to their action as central nervous depressants. E. S.

Absorption of Metallic Salts by Fish in their Natural Habitat. II. The Absorption of Nickel by *Fundulus Heteroclitus*. A. THOMAS (*J. Biol. Chem.*, 1924, **58**, 671—674; cf. *ibid.*, 1912, **11**, 381).—Nickel salts are not toxic to the *Funduli* in sea-water, but are extremely so in fresh-water, death being preceded by signs of intoxication in the fish. A number of analyses are given showing the dependence of the nickel absorbed on the concentration of the solution and on the time of immersion.

G. M. B.

Method of Determining the Biological Value of Protein. H. H. MITCHELL (*J. Biol. Chem.*, 1924, **58**, 873—903).—Details of the experimental methods are given, by which trustworthy data are secured on the nitrogenous metabolism of rats. The " metabolic nitrogen " of the fæces is measured by the total excretion of fæcal nitrogen on a nitrogen-free diet adjusted to have a " roughage " content approximately equal to that of the normal protein-containing diet. The excretion of nitrogen in the urine resulting from the catabolism of the tissues is not markedly depressed by protein feeding. The true basal catabolism of nitrogenous substances in the tissues is therefore measured by the total excretion of nitrogen in the urine in an adjacent period of feeding a nitrogen-free diet. This basal value is, however, subject to unexplained variations and must be redetermined at intervals in any long series of experiments.

The biological value of a protein is given by the percentage of the absorbed nitrogen (nitrogen intake — fæcal nitrogen of dietary origin) that is not eliminated in the urine. This value for the protein of a food is practically a coefficient of digestibility applied to the total protein present, and by means of it a " net protein value " of the food may be calculated. G. M. B.

Biological Value of Proteins at Different Levels of Intake. H. H. MITCHELL (*J. Biol. Chem.*, 1924, **58**, 905—922).—The biological values of the proteins (total nitrogen) of milk, maize, oats, rice, yeast, potatoes, navy beans, and the packing house by-product " tankage," have been determined by a modified Thomas method (preceding abstract). In the case of maize, milk, oats, and potatoes, experiments were made with rations containing 5 and 10% of protein, and, except for potatoes, the biological values were smaller at the higher level; the reasons for this are discussed. G. M. B.

Supplementary Relations among Proteins. H. H. MITCHELL (*J. Biol. Chem.*, 1924, **58**, 923—929).—If the biological value of the proteins in a mixture of two foods is found to be higher than that calculated from the values for each food used separately, assuming the effect to be directly additive, this shows the existence of a supplementary relation between the proteins of the two foods in question. A considerable supplementary relation has been shown to exist between the proteins of maize and of milk, and between those of maize and of "tankage.'" No such relation could be detected between gelatin and the proteins of the oat kernel. G. M. B.

Vitamins. I. Antineuritic Vitamins. G. Gaglio (*Atti R. Accad. Lincei*, 1923, [v], **32**, ii, 479—482).—Many different substances are able to exert antineuritic properties, some of them removing all, and others only certain, of the symptoms of experimental polyneuritis in pigeons. Of all the materials which have been investigated, rabbits' urine produces the most complete and permanent antineuritic effects. Investigations are necessary to ascertain the action of different mixtures of the chemical compounds known to occur in urine or blood plasma when administered to pigeons in conjunction with polished rice. The known facts warrant the statement that the conception of a single specific antineuritic principle is not justifiable. T. H. P.

Presence of Vitamin-*A* in Commercial Lecithin. F. Eichholtz (*Biochem. Z.*, 1924, **144**, 70—71).—From feeding experiments on white mice the presence of vitamin-*A* in lecithin (Witte) is inferred. J. P.

Effect of Diet on the Content of Vitamin-*B* in the Liver. T. B. Osborne and L. B. Mendel (*J. Biol. Chem.*, 1923, **58**, 363—367).—When rats are maintained on a diet free from vitamin-*B*, the normal store of this factor in the liver is to a large extent depleted. E. S.

Fat-soluble Vitamins. XV. Calcium and Phosphorus Relations to Growth and Composition of Blood and Bone with Varying Vitamin Intake. R. M. Bethke, H. Steenbock, and M. T. Nelson (*J. Biol. Chem.*, 1923, **58**, 71—103).—Normal calcification takes place in the bones of rats maintained on a diet otherwise deficient in fat-soluble vitamins when 20 c.c. of skimmed milk or 1 c.c. of whole milk per rat per day is added to the diet; with smaller additions, the calcification is poor.

The femurs and humeri of normal rats yield 45% of ash at the age of 24 days, 59% at 66 days, and 66% at maturity. The blood phosphates and calcium are slightly higher in young than in old animals.

A quantitative relation appears to exist between vitamin and calcium whereby poor assimilation of the latter due to deficiency of the former in the diet may be counteracted by increases in the calcium content of the diet. When, owing to lack of vitamin or of calcium salts, normal growth does not occur, there is a tendency for the calcium content of the blood and the ash content of the bones to suffer a diminution. Absence of fat-soluble vitamins from the diet depresses the calcium content of the blood, the depression being increased by the addition of phosphates to the diet; radiation with ultra-violet light for 10 minutes per day increases both the calcium and phosphorus content of the blood. E. S.

Influence of Diet on Teeth and Bones. G. TOVERUD (*J. Biol. Chem.*, 1923, **58**, 583—600).—When guinea pigs are maintained on a diet deficient in antiscorbutic vitamin, both histological and chemical changes occur in the front teeth. The total ash and calcium content decrease whilst the magnesium content increases. White rats fed on a diet poor in calcium show a low calcium and a high magnesium retention and fail to breed normally. Their bones are low in total ash, calcium, and phosphorus, whilst the composition of their teeth is abnormal, the molars being low in total ash, slightly low in calcium and phosphorus, and slightly high in magnesium, and the front teeth low in all respects. Changes in the diet can thus produce chemical changes in a formed tooth. E. S.

Effect of Hæmatoporphyrin on the Deposition of Calcium in the Bones of Rachitic Rats. E. C. VAN LEERSUM (*J. Biol. Chem.*, 1924, **58**, 831—844).—Injection of hæmatoporphyrin causes a great increase in sensitiveness of the subject to rays of light lying within the visible part of the spectrum. The effect of such injections was therefore studied on rats in which, by a restricted diet, signs of rickets had been produced. *X*-Ray- and photomicrographs are given showing that under this treatment deposition of calcium was proceeding and the effects were similar to those of cod-liver oil or irradiation treatment. Direct proof of the influence of light has not yet been obtained. G. M. B.

Dietary Requirements for Reproduction. I. Nutritive Value of Milk Proteins from the Point of View of Reproduction. II. Existence of a Specific Vitamin for Reproduction. B. SURE (*J. Biol. Chem.*, 1924, **58**, 681—692, 693—709).—Rats fed on a complete artificial diet, with milk protein as a source of nitrogen, were found either to be sterile or to be unable to rear their young. Cod-liver oil was substituted for butter fat as a source of vitamin-*A*; vitamin-*B*, the antirachitic factor, and the necessary salts and iodine were provided. The further addition of casein, arachin, or edestin with 0·4% of cystine and in other experiments of lysine, proline, tyrosine, and trytophane still failed to secure normal reproduction. From these experiments and those of Evans and Bishop (*J. Metabol. Research*, 1922, **1**, 319, 335; 1923, **3**, 201, 233) it is concluded that there exists another hitherto unrecognised vitamin which is essential for reproduction. This factor has been found by breeding experiments to be present in Georgia velvet bean pod meal, polished rice, yellow corn, and rolled oats.

Accepting Macdonald's opinion that the "vitamin-*D*" of Funk and Dubin (A., 1922, i, 203) is wrongly classified as a vitamin, the term "*D*" is proposed for the antirachitic factor of McCollum and others (*J. Biol. Chem.*, 1922, **53**, 293), and the term "*E*" is adopted for the new vitamin which affects reproduction. G. M. B.

Chemical Changes in the Lipoids of Kidneys with Degenerated Cells. P. SCHNAPP (*Z. physiol. Chem.*, 1924, **133**, 62—79).—By clamping the vascular system of the kidney degeneration is induced in the cells of this organ. The ethereal extract of such degenerated kidneys showed a lower total lipoid content, a lower acidity (Spaltungzahl), and a lower iodine value than the normal kidney. On the other hand, the unsaponifiable and the saponifiable (Restzahl) residue showed an increase above the normal. S. S. Z.

R. Engeland and W. Biehler's Article "Some Compounds Extracted from Human Skeletal Muscle" (A., 1923, i, 72). J. A. SMORODINCEV (*Z. physiol. Chem.*, 1924, **132**, 328).—Attention is directed to the investigations by the author on the extractives of human and mammalian skeletal muscle (*Z. physiol. Chem.*, 1913, **87**, 12; 1914, **92**, 214; 1922, **123**, 116). J. P.

Saccharophosphatase in Human Organs. E. FORRAI (*Biochem. Z.*, 1924, **144**, 149—151; cf. A., 1922, i, 960; 1924, i, 120). —Saccharophosphatase is present in normal human pancreas and suprarenal bodies, but is absent from normal kidneys, testes, heart muscle, thyroids, skeletal muscle, and blood-serum. In cancerous conditions, it is found in certain organs (notably the liver) from which it is normally absent. J. P.

State of Combination of Nucleic Acids in Cell Nuclei. H. STEUDEL and T. TAKAHATA (*Z. physiol. Chem.*, 1924, **133**, 165—172).—The nucleic acid of yeast-cells is present in a free state and not in combination with protein. Nucleic acid was obtained from yeast by extraction with sodium chloride and precipitation with hydrochloric acid by Clarke and Schryver's method. S. S. Z.

Biological Significance of Nucleic Acid Compounds. E. HAMMARSTEN (*Biochem. Z.*, 1924, **144**, 383–465).—An important paper, in which the conductivity, hydrogen-ion concentration, osmotic pressure, and viscosity of thymus nucleic acid and its salts have been studied and discussed.

Thymonucleic acid is a strong polyphosphoric acid in which each of the four phosphorus atoms is associated with one dissociable hydrogen atom. Fresh thymonucleic acid dissolves to a concentration of about $3 \times 10^{-3}M$, yielding a turbid solution. It is supposed that the suspended particles causing the turbidity are due to the undissociated acid. From dialysis experiments carried out on the quadrivalent sodium salt of thymonucleic acid it is found that the salt possesses an apparent degree of dissociation of 0·25. The sodium salt of thymonucleic acid shows an osmotic pressure corresponding with that of the undissociated salt. On the other hand, when the acid is in combination with trimethyl-, triethyl-, or tripropyl-amine or with tetramethylammonium hydroxide, the osmotic pressure increases with the increase in volume of the cation. The sodium salt manifests the Donnan equilibrium in neutral solution. The relative viscosity of the sodium salt is very high, and it combines in dilute solutions with about 400 times its volume of water. Various agencies which lower the viscosity of its solution bring about an only partly reversible gel formation, which is most probably due to a phase reversal. The relative viscosity of the sodium salt is reduced by kations even in concentrations of less than $10^{-3}N$. The valency of the kations is of importance. Strong acids reduce the relative viscosity of sodium thymonucleate; the maximum reduction is reached when two of the sodium atoms are replaced by hydrogen. The viscosity of protein–nucleic acid salts is raised by the addition of sodium chloride, probably because of the formation of the tetrasodium salt by double decomposition. The ampholyte salts of thymonucleic acid are hydrolysed during dialysis if the ampholyte is diffusible. Salts of thymonucleic acid and proteins with an isoelectric point of p_H 4·7 exist as precipitates in equilibrium with the protein in hydrogen-ion concentrations approximating to the isoelectric point. When an excess of the sodium salt of thymonucleic acid is added, the protein salts dissolve in water at lower hydrogen-ion concentrations than $3—3{\cdot}5\times10^{-3}$. Protein and thymonucleic acid combine in varying proportions. Proteins with an isoelectric point of p_H 4·7 combine with thymonucleic acid during the first two stages of dissociation of the acid more readily than during the later stages of dissociation. Double decomposition takes place when the neutral salts of thymonucleic acid and diamino-acids are dialysed in the presence even of small quantities of sodium chloride with the formation of the sodium salt of the nucleic acid and the chloride of the diamino-acid. Histone compounds of thymonucleic acid are soluble in water when at least two of the sodium atoms of the salt and an equivalent of histone are in combination with 1 mol. of nucleic acid. The bearing of the above experimental observations on the biology of the cell is fully discussed, particularly with regard to the importance of the Donnan effect. S. S. Z.

Carbohydrate Group of Thymonucleic Acid. H. Steudel and E. Peiser.—(See i, 438.)

Distribution of Pentose Compounds in the Pancreatic Tissues of the Ling Cod (*Ophiodon Elongatus*, Girard). C. Berkeley (*J. Biol. Chem.*, 1923, **58**, 611—616).—Considerably more pentose is present in the islet than in the zymogenous tissue of the pancreas of the ling cod. It is suggested that it is produced from dextrose which has been activated by insulin.
E. S.

Nitrogenous Extractives from the Spleen. S. Demianowski (*Z. physiol. Chem.*, 1924, **132**, 109—133).—In spite of careful investigation of the phosphotungstic acid precipitate from the extract of the spleen of the freshly-killed ox, the presence of carnitine, methylguanidine, or of carnosine could not be detected. Tryptophan, approximately 0·0056% of the fresh horse spleen pulp, is extracted by water at 55—60°. Tryptophan is also extracted under similar conditions from the fresh spleens of oxen. Organic compounds other than tryptophan such as arginine, carnosine, tyrosine, or cystine are precipitated by Hopkins' reagent.
W. O. K.

Hydrogen-ion Concentrations within the Alimentary Tract of Insects. W. J. Crozier (*J. Gen. Physiol.*, 1924, **6**, 289—293).—Larvæ of dipterous insects (*Psychoda* and *Chironomus*) were kept in solutions containing an indicator (bromophenol blue, phenol red, or neutral red), and then removed and dissected. The colours of the fluid in the various sections of the intestinal canal indicated that the p_H was approximately as follows: in the œsophagus, 7·1; the cardiac chamber, 6·2; the mesenteron, 7·5; and the hind-gut, 6·4. W. O. K.

Behaviour of Calcium, Potassium, Chlorine, and Phosphorus in Milk and the Technique of Ultrafiltration. C. Wha (*Biochem. Z.*, 1924, **144**, 278—284).—Fifty % of the calcium of cow's milk is present in a colloidal non-diffusible form (cf. Rona and Michaelis, *ibid.*, 1909, **21**, 114), but in the process of souring all the calcium becomes ionised and diffusible. Of the phosphorus in milk 60% is in a colloidal state, whilst all the potassium and chlorine present is diffusible (cf. György, this vol., i, 120). A vacuum dialyser of collodion is described. J. P.

Influence of Phosphate and Bicarbonate on the Dissociation of Calcium Compounds in the Cerebro-spinal Fluid. H. Behrendt (*Biochem. Z.*, 1924, **144**, 72—80).—Using the method of Brinkman and van Dam, 20% of the total calcium (5 mg.%) of the cerebro-spinal fluid of children is found in the ionised condition at p_H 7·6—7·7. Sodium hydrogen carbonate and sodium hydrogen phosphate solutions of the same p_H as the fluid markedly lower the calcium-ion concentration, the phosphate exerting an effect more than twice that of the carbonate. J. P.

Ferments in the Amniotic Fluid. K. Maeda (*Biochem. Z.*, 1924, **144**, 1—8).—The reaction of the amniotic fluid varies between p_H 7·5 and 7·7. Diastase is present in the fluid in greater amount than in the blood from which it is derived. Lipase is sometimes present and originates from the fœtal intestine. Pepsin, rennin, and thrombin (fibrin ferment) occur only in traces. Trypsin is absent. J. P.

Urinary Excretion of Organic Acid and its Variation with Diet. L. McLaughlin and K. Blunt (*J. Biol. Chem.*, 1923, **58**, 267—284).—Determinations have been made by Van Slyke and Palmer's method (A., 1920, ii, 131) of the organic acid content of the urine of eight normal women. Under normal conditions, values (uncorrected for creatinine) equivalent to 6·8—10 c.c. of 0·1*N*-acid per kg. per day, which are similar to those obtained by Van Slyke and Palmer (A., 1920, i, 459) for men, were obtained. The amount excreted per hour by day (*i.e.*, during activity) was much greater than that by night. During fasting, the hourly excretion was equivalent to 15—24 c.c. of 0·1*N*-acid. This was markedly increased by diets rich in fruit or protein, but was only slightly affected by diets poor in these substances. One-third to one-half of the acids titrated by the above method consists of uric acid, creatinine, creatine, and amino-acids. Diets which increase the organic acid excretion also increase that of uric acid. E. S.

Creatinine Excretion of Women. L. McLaughlin and K. Blunt (*J. Biol. Chem.*, 1923, **58**, 285—290).—Determinations of the creatinine coefficients of eight normal women gave values (6·3—9·6 mg. of creatinine nitrogen per kg. per day) similar to those obtained by others for men. The higher values were obtained in the case of women who were below normal weight. There was no regular difference between the amounts excreted by day and those excreted by night. Creatine was almost invariably present in the day urine of one healthy woman. E. S.

Excretion of Ammonia and Nitrogen. R. S. Hubbard (*J. Biol. Chem.*, 1924, **58**, 711—719).—As the experiments of Marshall and Crane (A., 1923, i, 628) led to different conclusions from those drawn by Hubbard and Munford (A., 1923, i, 169) by a statistical examination of the results of analyses of human urine, a more extended series of figures has been obtained and examined as before. The results in general confirm the conclusions of Hubbard and Munford as to the excretion of ammonia by normal human subjects. G. M. B.

Effect of Injections of Sodium Phosphates and Sodium Hippurate upon the Excretion of Acid and Ammonia by the Kidney. B. M. Hendrix and J. P. Sanders (*J. Biol. Chem.*, 1923, **58**, 503—513).—Injections of disodium hydrogen phosphate or of sodium hippurate in fasting dogs cause an increase in the titratable acidity and in the ammonia content of the urine, the sum of these increases being practically equivalent to the salts injected. The results obtained support the view of Nash and Benedict (A., 1922, i, 191) that a portion of the urinary ammonia is formed in the kidney, but it is suggested that part may have its origin in the intestine. The kidney can probably retain sodium from sodium salts of acids as strong as hippuric acid, but is unable to do so in the case of much stronger acids. E. S.

Spontaneous Crystallisation of Uric Acid from Urine. L.-C. Maillard (*Bull. Soc. Chim. biol.*, 1923, **5**, 930—934).—It has been thought by some authors that uric acid is soluble in urine because it exists therein as a complex compound. The present author refers to an observation of his that uric acid crystallises spontaneously from urines which are markedly acid and show a high formol titration figure. He suggests that this may indicate that the compound mentioned above may be of the nature of an amino-acid complex. C. R. H.

Natural Porphyrins. V. Coproporphyrin in the Urine and Serum in Normal and Pathological Conditions. H. Fischer and W. Zerweck (*Z. physiol. Chem.*, 1924, **132**, 12—33).—Urine (1000 parts) is made acid with acetic acid (3 parts) and extracted with ether (1000 parts). The ether is washed with water (20 parts) and extracted with 25% hydrochloric acid (3 parts) and the solution observed spectroscopically. Coproporphyrin, if present, shows bands with centres at λλ *ca.* 592, 548, and 491. To the acid solution, ether, sodium acetate, and sodium hydroxide solution are added so that the mixture is still acid with acetic acid. The ethereal solution is then washed, and if coproporphyrin is present, it shows bands at λλ *ca.* 624, 567, 528. The coproporphyrin may be again extracted with acid and observed. Coproporphyrin has been found in the urine of normal individuals independently of whether their food has contained flesh or blood (cf. Schumm, A., 1923, i, 631, who found porphyrin present in normal subjects only after flesh or blood was consumed). From the united ethereal extracts, a solution containing cotporphyrin methyl ester, identified spectroscopically, was prepared. Coproporphyrin has been identified in the urine of guinea-pigs, in normal human serum, and in the serum of the horse, ox, and fowl. Investigations of the porphyrin in blood and urine in certain pathological conditions in man, as pernicious anæmia, hæmolytic icterus, and urobilinuria, are described. W. O. K.

Hæmatoporphyria Congenita. IV. The Identification of Natural Porphyrins in Serous Fluids and in Organs. O. SCHUMM (*Z. physiol. Chem.*, 1924, **132**, 62—71).—By means of spectroscopic observations, the presence of urinoporphyrin and of cotporphyrin has been detected in the pleural exudate from a patient suffering from hæmatoporphyria congenita. Details are given of the methods to be followed in examining such fluids or organs for the presence of porphyrins. W. O. K.

Hæmatoporphyrin of Human Fæces. A. PAPENDIECK (*Z. physiol. Chem.*, 1924, **133**, 97—99).—Polemical. S. S. Z.

Ether Extract of Fæces. A. D. HOLMES and R. H. KERR (*J. Biol. Chem.*, 1923, **58**, 377—381).—Experiments made in connexion with the digestibility of edible fats indicate that the amount of unutilised fat excreted in the fæces in the form of soaps is insignificant. Further, the ethereal extract of the fæces appears to be of a uniform composition independent of the particular fat ingested. E. S.

Decolorisation of Ethereal Extracts. J. MARKOFF (*Compt. rend. Soc. Biol.*, 1923, **89**, 113—115; from *Chem. Zentr.*, 1924, i, 80).—Directions are given for the use of phosphotungstic acid for decolorising ethereal extract of fæces. Preliminary removal of the ether by distillation is necessary. G. W. R.

Adsorption and the Distribution of Drugs in the Organism. III. E. KEESER (*Biochem. Z.*, 1924, **144**, 536—544).—There is no parallelism between the adsorption capacity of charcoal for alkaloids and iodine *in vitro* and its detoxicating effect in the intestinal tract of the dog. The method by which a charcoal is prepared and not its origin is the determining factor of its adsorptive capacity. Strychnine nitrate is adsorbed more readily than morphine hydrochloride. In the presence of sodium bicarbonate, morphine hydrochloride and strychnine nitrate are adsorbed to a higher extent by charcoal. The electric charge changes in blood charcoal (Kahlbaum) at p_H 3·5, in beech charcoal (Kahlbaum) at p_H 6·6, in "carbovent" at p_H 3·9. There is no change in the electric charge in bone charcoal (Kahlbaum), beech charcoal (Merck), and lime tree charcoal (Kahlbaum) at the investigated range of hydrogen-ion concentration. S. S. Z.

Action of Different Substances, particularly the so-called Heart Remedies, on Disturbances of the Rhythm of the Heart. W. SIMON (*Arch. Pharm. Exp. Ther.*, 1924, **100**, 307—315).—Only caffeine, calcium salts, human serum, and especially adrenaline, out of a large number of substances investigated, were able to relieve the disturbance of the rhythm of an isolated frog's heart, caused by cocaine or strychnine. W. O. K.

Physico-chemical Technique for Detection of Polonium injected into Organs. (MME.) J. S. LATTÈS and A. LACASSAGNE (*Compt. rend.*, 1924, **178**, 630—632; cf. this vol., i, 347).—The organ into which polonium has been injected is treated with potassium chlorate and hydrochloric acid until destroyed (fats, unaffected by this reagent, may then be separated mechanically); the solution obtained is boiled in presence of silver foil, and the polonium deposited on the latter determined by measuring its activity. This method is much more sensitive than the auto-histo-radiographic method, but obviously gives only the mean polonium content of an organ and not the distribution of that element. E. E. T.

Influence of "Alkaloids" on Permeability. W. HEUBNER (*Biochem. Z.*, 1924, **144**, 351—352).—The suggestion is made that the observations of Brinkmann and Szent-György (A., 1923, i, 974) on the action of morphine and codeine salts on the permeability of a collodion membrane to hæmoglobin, may have had their origin in the action of the anion; the work of Rhode (A., 1922, i, 1088) on the action of morphine chloride and codeine phosphate on hæmolysis is cited in this connexion. J. P.

Vasodilatation by Amino-acids in Isolated Dog Kidneys. H. FREDERICQ and L. BROUHA (*Compt. rend. Soc. Biol.*, 1923, **89**, 665—667; from *Chem. Zentr.*, 1924, i, 213).—Glycine, *l*-leucine, *d*-alanine, and *dl*-valine exert a vasodilatory effect in isolated dog kidneys, which is demonstrated by the increased flow of liquid from the renal vein and the ureter. The action of *dl*-phenylalanine is less definite. G. W. R.

Effect of Amino-acids on Exchanges in Isolated Organs. H. FREDERICQ and L. MÉLON (*Compt. rend. Soc. Biol.*, 1923, **89**, 668—669; from *Chem. Zentr.*, 1924, i, 213; cf. preceding abstract).—Isolated dog kidneys were perfused with Locke solutions containing 0·5% of different amino-acids. The first result was the production of an acid reaction, an effect not observed with Locke solution alone. *d*-Alanine and *l*-leucine cause an increase in nitrogen titratable by formaldehyde in the liquid. Other compounds have no effect or depress the amount of nitrogen titratable by formaldehyde. G. W. R.

Detection of Toluene in Organs and its Distribution in the Organism. S. Kuroda (*Biochem. Z.*, 1924, **144**, 287—293).—The toluene is distilled from a suspension of the organ in water and collected in carbon tetrachloride. It is nitrated, dissolved in water, made alkaline with sodium hydroxide, extracted with ether, and finally weighed. After toluene poisoning, the central nervous system of dogs and guinea pigs contains more toluene than the other organs, with the exception of the spleen, and the leucocytes of the blood are diminished. J. P.

Effect of Chloroform and Phosphorus Poisoning on Carbohydrate Tolerance. M. Bodansky (*J. Biol. Chem.*, 1923, **58**, 515—522).—Experiments on dogs indicate that the lævulose tolerance test described in this paper is of great value in measuring the degree of liver injury during chloroform and phosphorus poisoning. Dextrose and galactose are not suitable for this purpose. E. S.

Action of Hydrazine and some of its Derivatives in producing Liver Injury as measured by the Effect on Lævulose Tolerance. M. Bodansky (*J. Biol. Chem.*, 1924, **58**, 799—811).—The degree of liver injury produced in dogs by hydrazine and a number of derivatives have been determined by the lævulose tolerance test previously described (cf. preceding abstract), and the results confirmed by *post-mortem* examination. Hydrazine, phenylhydrazine, *s*-di*iso*propylhydrazine, and ββ-azopropane ($CHMe_2{\cdot}N{:}N{\cdot}CHMe_2$) are highly injurious to the liver, whereas methylphenylhydrazine, diphenylhydrazine, acetylphenylhydrazine, and *p*-hydrazinobenzoic acid have much less effect. G. M. B.

Influence of Hydrazine on Blood Concentration and Blood-sugar Content. F. P. Underhill and S. Karelitz, jun. (*J. Biol. Chem.*, 1923, **58**, 147—151).—The hypoglycæmia produced in dogs by the subcutaneous injection of hydrazine hydrate (cf. A., 1914, i, 632; 1915, i, 1037) is preceded by a transitory condition of hyperglycæmia; no sugar, however, appears in the urine. Hydrazine poisoning also causes a marked increase in blood concentration, which is ascribed both to the loss of fluid and to the inability of the animal to retain food or water; this effect probably contributes largely to the fatal results. There is no direct relationship between the degree of blood concentration and the extent of hypoglycæmia. E. S.

Specificity of the Intracellular Hydrogenases in Frog's Muscle. M. E. Collett (*J. Biol. Chem.*, 1924, **58**, 793—797).—The influence of certain protoplasmic poisons on the oxidation of citric and succinic acids by washed frog's muscle in presence of methylene-blue has been examined. The action is more readily inhibited by phenol and chloral hydrate in the case of the oxidation

of citric acid than in that of succinic acid: this order is reversed with poisons such as tellurites, selenites, selenates, and arsenates. The conclusion is drawn that there are two enzymes specific for the oxidation of citric and succinic acids, respectively.
G. M. B.

Fungal Product, $C_6H_6O_4$, and its Behaviour on Hydration. N. WIJKMAN (*Z. physiol. Chem.*, 1924, **132**, 104—108).—When *Aspergillus* spp. are grown on a medium containing sucrose in quartz or paraffined glass flasks and the acidity of the medium is kept within certain limits, there regularly separate from the culture liquid crystals of a *substance*, which after sublimation under a low pressure melts at 154° and possess the formula $C_6H_6O_4$ [*copper* salt, $(C_6H_5O_4)_2Cu,H_2O$; *acetyl* compound, $C_6H_4O_2(OAc)_2$]. On treatment with hydrogen in presence of a catalyst, a compound, m. p. 80—90°, b. p. *ca.* 200°/1 mm., is obtained, which appears to be hydroglucal, although this has not been proved conclusively.
W. O. K.

Simultaneity of Two Contradictory Toxic Effects (Immunity and Anaphylaxis) on the Same Cell. C. RICHET, (MLLE.) E. BACHRACH, and H. CARDOT (*Compt. rend.*, 1924, **178**, 535—537).—The lactic acid bacillus, if cultivated in presence of copper sulphate (or of mercuric chloride) and potassium arsenate together, acquires simultaneously sensitivity towards the former and immunity towards the latter. E. E. T.

Diphtheria Toxin and Anatoxin. Flocculating Power and Immunising Properties. G. RAMON (*Ann. Inst. Pasteur*, 1924, **38**, 1—10).—Antidiphtheria serum produces a flocculation when added to diphtheria toxin. The amount of antitoxin required to cause flocculation measures the toxicity of the toxin. When diphtheria toxin, to which formalin (3 or 4 parts per 1000) had been added to prevent bacterial contamination, was kept at 40—42°, it lost its toxicity, but retained its property of being flocculated by antitoxin. The *anatoxin* so produced retains also the immunising power, *in vivo*, of the original toxin, and its strength may be estimated by finding the amount of antitoxin required to cause flocculation, as this has been found experimentally to be proportional to its immunising effect. W. O. K.

Antiseptic Value of Hexamethylenetetramine *in vitro*. A. DUTHOIT (*Compt. rend. Soc. Biol.*, 1923, **89**, 656—658; from *Chem. Zentr.*, 1924, i, 71).—With 2% hexamethylenetetramine in Ringer solution, paratyphoid and typhoid bacilli are completely killed in 4—7 days. *Bacillus coli* and pneumobacilli are not completely killed, even after 10 days. The antiseptic effect of hexamethylenetetramine does not reside in the formaldehyde group.
G. W. R.

Antiseptic Effect of Hexamethylenetetramine. A. DUTHOIT (*Compt. rend. Soc. Biol.*, 1923, **89**, 658—660; from *Chem. Zentr.*, 1924, i, 71; cf. preceding abstract).—Data are given for the bactericidal effect of the gall of dogs on different species of bacteria with and without preliminary injection of hexamethylenetetramine. It is found that hexamethylenetetramine is less effective as an antiseptic *in vivo* than *in vitro*. G. W. R.

Effects of Electrolysis on Animal Tissue Enzymes. Abundance of Silicic Acid in the Ash. F. MAIGNON (*Compt. rend.*, 1924, **178**, 654—657).—The enzymes from all body-tissues examined contained silica and calcium. Some tissue enzymes also contained characteristic quantities of phosphorus, arsenic, magnesium, and iron. Electrolysis of the enzyme preparations in aqueous solutions gave a coagulum at both anode and cathode with concomitant loss of therapeutic properties (cf. this vol., i, 350). E. E. T.

Rapid Analysis of Sugars. Purification and Concentration of Enzyme Solutions. F. W. REYNOLDS (*Ind. Eng. Chem.*, 1924, **16**, 169—172).—Yeast extracts may be freed from colour and substances causing turbidity by dialysing or by washing on an ultra-filter and subsequently acidifying with acetic acid, whereby the substances causing turbidity are flocculated and can be removed by filtration through paper. Highly active preparations of invertase and melibiase may be obtained by concentrating crude or purified yeast extracts by ultra-filtration. A simple ultra-filter with a collodion membrane is described and illustrated. The impurities, especially those which are optically active, are largely eliminated and not concentrated with the enzyme. The activity of enzymes prepared by these means was about eight times that of the ordinary yeast extracts, and was such that sucrose solutions could be completely hydrolysed with their aid in 15 minutes at the ordinary temperature. Ultra-filtration should be useful as a means of concentrating other enzymes for use as analytical reagents and also in the study of the enzyme action of plant and fruit juices. H. C. R.

Purification of Toxins, Ferments, and other active Biological Organic Colloids. L. MICHAELIS and H. DAVIDSOHN (*Biochem. Z.*, 1924, **144**, 294—297).—Details are given of the patented process (1912) used for purifying toxins, ferments, etc., by precipitation at the isoelectric point or at a definite hydrogen-ion concentration. J. P.

Mechanism of Alcoholic Fermentation. III. A. LEBEDEV (*Z. physiol. Chem.*, 1924, **132**, 275—296).—Yeast incubated with sucrose in the presence of sodium sulphite and sodium or potassium dihydrogen phosphate, yields compounds the osazones of which (m. p. 202—209°) are free from phosphorus, but in the presence of these phosphates alone the osazones obtained (m. p. 143—152°) are those of phosphate esters differing from hexose biphosphate, whilst the presence of disodium or dipotassium hydrogen phosphates may or may not lead to the formation of a phosphate ester, the results varying with different yeast preparations. Whilst the analyses of the various phosphate esters has not yet been completed, it is apparent that it is possible to control, not only the amount, but also the nature of the hexose phosphate formed during yeast fermentation. The author supposes yeast fermentation to proceed in acid solution as follows: hexose ⟶ two trioses ⟶ glyceric acid ⟶ pyruvic acid ⟶ acetaldehyde ⟶ alcohol ⟶ carbon dioxide, whilst in neutral or alkaline solutions glycerol is formed along with glyceric acid and acetic acid accompanies alcohol. The formation of the four known hexose phosphates (including the new osazone-forming monophosphate described by the author) is correlated with the preliminary formation of glyceraldehyde, dihydroxyacetone, and the two corresponding monophosphates of these compounds. In accord with the author's views the presence of nine individual enzymes in the zymase complex is postulated. J. P.

Influence of Amines on Fermentation. II. J. ORIENT (*Biochem. Z.*, 1924, **144**, 353—360).—The effect of various alkylamines and their salts, glucosamine and its hydrochloride, diamines, and indole derivatives on yeast fermentation has been investigated. In general the salts of amines and diamines increase, whilst the free bases diminish fermentation. Indole has a slight inhibiting action, whilst scatole has the reverse effect (cf. A., 1923, i, 171). J. P.

Action of Drugs containing Hydroxymethylanthraquinones on Fermentation. J. ORIENT (*Biochem. Z.*, 1924, **144**, 361—365).—The action of various pharmacological preparations of *Rheum*, *Aloe*, *Senna*, *Cascara*, *Frangula*, *Cassia*, *Jalappa*, and *Colocynthis* on yeast fermentation has been investigated. In general fermentative action is increased, more especially by the rhubarb group rich in hydroxytrimethylanthraquinone. J. P.

Fermentation with Non-ferments. W. BIEDERMANN (*Z. angew. Chem.*, 1924, **37**, 71—73).—If a solution containing diastase (*e.g.*, saliva or a solution of saliva albumose) is heated, a turbidity appears at 70—80°, owing to partial coagulation of the "zymogen," and the diastatic power is considerably diminished; it does not, however, disappear even by heating the solution to boiling, and may be considerable in the presence of oxygen. This regeneration by means of air is further enhanced by the presence of the above coagulate. A solution of saliva ash, or even simple salt solutions (particularly sodium chloride), can produce a slow degradation of amylose to sugar, although here again thorough aëration is necessary. The activity of the salts is increased, not only by the specific protein, but also by the inactive degradation products, the presence of amino-acids (*e.g.*, glycine, leucine) being found advantageous. It appears that the organic ferment, and not the inorganic substance, should be regarded as the activator. Treatment of fibrin with steam yields solutions which, after addition of sodium chloride or a suitable phosphate mixture, are capable of fermenting amylose, if an adequate supply of air is maintained. By employing very dilute ferment solutions amylose can be converted into dextrin alone, without a simultaneous production of sugar. It may, finally, be said that, below a certain dilution, small quantities of saliva diastase have exactly the same action as the "complementary" inorganic salts alone, provided the latter are in a corresponding concentration. W. T. K. B.

Comparison of the Action of Acids and Enzymes in Hydrolytic Phenomena. H. COLIN and A. CHAUDUN (*J. Chim. physique*, 1923, **20**, 471—483).—The hydrolysis of sucrose by diastase is considered theoretically and it is shown that the velocity of the reaction does not increase with the concentration of the sucrose (a) nor with the concentration of the diastase (n), but rather with the ratio of these concentrations, a/n. The condition under which the reaction follows Wilhelmy's law is that a/n shall be less than a value a'/n' which is characteristic of the solution of diastase employed. When $a/n<a'/n'$ then the amount of sucrose transformed each instant can be calculated by Wilhelmy's formula $x=a(1-e^{-kt})$, which means that under these conditions the rates of hydrolysis by acids and diastase are identical. When $a/n>a'/n'$ the initial velocity $v=f(an)$ is independent of a and proportional to n. These facts indicate that the enzyme forms a complex with the sugar, which then decomposes with a finite velocity in keeping with the law of mass action. The above statements apply exactly to the action of emulsin on glycosides. The velocity of inversion by diastase decreases with increasing viscosity of the solution, but in the case of hydrolysis with acids the viscosity appears to have no influence on the velocity of the change. J. F. S.

Inactivation of Invertase in Fresh Yeast by Silver Nitrate. H. VON EULER and E. WALLES (*Z. physiol. Chem.*, 1924, **132**, 167—180).—The invertase of yeast-cells is inactivated by silver nitrate as the latter is taken up from the solution by the cells. It may regain its activity by self-regenerative processes or by treatment with hydrogen sulphide. The phenomenon is therefore parallel to the inactivation of yeast enzymes in solution (Euler and Myrbäck, A., 1922, i, 959). Yeast inactivated by silver nitrate and regenerated by treatment with hydrogen sulphide shows, after incubation, an increased activity. Owing to these protective mechanisms the invertase of the living yeast-cell is two hundred times more resistant to the toxic action of silver than is the same amount of the enzyme in solution. Zymase is much more susceptible to inactivation by silver than is invertase. J. P.

Invertase. III. H. VON EULER and K. JOSEPHSON (*Ber.*, 1924, **57**, [*B*], 299—302; cf. A., 1923, i, 721).—The maximum purification of invertase preparations by the author's methods appears to be reached when the value If^0 attains about 250.

Determinations of the molecular weight of invertase by measurements of diffusion indicate that the "active group" is contained in or associated with a complex of molecular weight about 20,000.

Specimens of invertase have been obtained in which the ash does not exceed 0·13%; the higher ash content of previous preparations is therefore due to impurities. The acidic and basic dissociation constants have been determined provisionally to be $K_a=10^{-7}$ and $K_b=10^{-11}$, respectively. The isoelectric point of invertase at 20° is calculated to be at p_H 5. H. W.

Affinity of Invertase for Different Sugars. H. VON EULER and K. JOSEPHSON (*Z. physiol. Chem.*, 1924, **132**, 301—327).—At p_H 4·5 invertase of bottom yeasts has a marked affinity for both α- and β-dextrose, the affinity being slightly greater in the latter case than in the former. The affinity for lævulose is of the same order as for dextrose. In contrast to the findings of Kuhn (*Z. physiol. Chem.*, 1923, **127**, 234; **129**, 57), no general support is forthcoming for the view that separate "gluco-" and "fructo-" invertases exists. The affinity of invertase for other hexoses and pentoses depends on the presence of a free reducing group (aldehydic or ketonic) and on the configuration of the remainder of the molecule, which may be considerably modified without entirely abolishing the affinity. In general, the β-forms of the hexoses and pentoses show a greater affinity than the α-forms except in the cases of dextrose and xylose, where both stereoisomerides react practically alike. A relation appears to exist between the configuration of the sugar molecule and the relative affinity of invertase for its α- and β-forms; thus the pairs dextrose–xylose and galactose–arabinose give parallel results. The affinity of invertase for the disaccharides has also been studied but no very definite conclusions are drawn. J. P.

Uniformity in Invertase Action. J. M. NELSON and F. HOLLANDER (*J. Biol. Chem.*, 1923, **58**, 291—304).—The abnormality observed with certain invertase preparations (A., 1922, i, 388) has been shown to be due to inactivation. Thus, when the abnormal preparations were incubated at 25° with a citrate buffer mixture at p_H 4·5 (the acidity at which the abnormality was observed) some loss of activity occurred, whilst this was not the case with normal preparations. Further, addition of sodium chloride or of boiled normal invertase prevented inactivation in the case of the preparation which was rendered normal by this treatment, but did not do so with the second abnormal preparation, which could not be rendered normal in this way. At 25° the point of maximum stability of one abnormal and two normal invertase preparations was found to lie, not at the acidity for maximum activity (p_H 4·5; cf. Euler and Laurin, A., 1920, i, 506), but on the alkaline side of this (about p_H 5·8). E. S.

Enzyme Adsorption. I. H. KRAUT and E. WENZEL. A Contribution to the Knowledge of "Invertin" of Willstätter and his Collaborators (*Z. physiol. Chem.*, 1924, **133**, 1—21).—The adsorption curve obtained by adsorbing the invertase of autolysed yeast juice with aluminium hydroxide deviates from the normal adsorption isotherm. The author argues that this is due to the interference of impurities adsorbed from the juice. Any change in the initial activity of an impure juice yields a different adsorption curve. In certain cases, it is even possible for aluminium hydroxide to adsorb more of the enzyme out of dilute impure solutions than out of similar solutions of higher concentration. The adsorption value rises with the purity of an invertase preparation. S. S. Z.

Influence of Alkaloids of the Atropine, Cocaine, and Morphine Groups on Yeast Invertase. P. RONA, C. VAN EWEYK, and M. TENNENBAUM (*Biochem. Z.*, 1924, **144**, 490—519).—A series of alkaloids of the above groups have been found to possess an inhibiting influence on the action of yeast invertase. Although the intensity of the inhibition varies with the various alkaloids, the general inactivating influence proceeds logarithmically according to the concentration of the alkaloid present. The inhibition is reversible, and is influenced by the hydrogen-ion concentration of the medium. No connexion exists between the optical configuration and the inhibitory power of *dl*-atropine and *l*-hyoscyamine; *l*-cocaine and *dψ*-cocaine; and *l*-ecgonine and *d*-ecgonine. In none of these three cases was there any difference between the inhibitory power of the isomers. Tropine inhibits much less markedly than atropine, whilst tropic acid does not inhibit at all; nor does an equimolecular mixture of tropine and tropic acid have a greater inhibiting effect than tropine alone. *d*- and *l*-Ecgonine do not inhibit, but, on the other hand, the chemically-related cocaine does. The substitution of the hydrogen of morphine by the methyl group (codeine) produced no apparent change in inhibitory power, but substitution by ethoxyl (dionine) produced a small though definite change. S. S. Z.

Heat and Radiation Inactivation of Malt Amylase. H. LÜERS and P. LORINSER (*Biochem. Z.*, 1924, **144**, 212—218).—The zone of maximal thermostability of malt amylase is displaced towards higher p_H values by increased concentration of an acetate buffer. Gelatin, egg-albumin, and gum arabic protect the amylase from heat inactivation especially between p_H 6·0 and 7·0, and produce a flattening of the zone of maximum stability. Maltose has a similar protective influence and a direct proportionality exists between log $C_{maltose}$ and the coefficient of inactivation. The inactivation of amylase by ultra-violet radiation follows neither the mono- or bi-molecular equation, nor the Schütz law. The effect of alterations in the hydrogen-ion concentration is much less marked in this case than in that of heat-inactivation. The temperature coefficient for ultra-violet inactivation is k^{30}/k^{20} 1·30, and physicochemically the two methods of inactivation are dissimilar. J. P.

Ferments and Light. IV. Diastase. III. L. PINCUSSEN and F. DI RENZO (*Biochem. Z.*, 1924, **144**, 366—371; cf. A., 1924, i, 107).—The inactivation by ultra-violet light of 0·1% of malt diastase acting on 1% starch solution at varying p_H proceeds as a unimolecular reaction, whilst in the presence of 0·5% of starch only the later stages correspond with the unimolecular equation. The departure from the simple equation is still more marked in the presence of 0·25% of starch. A 0·2% solution of the enzyme gives complex results in the presence of 1·0, 0·5, and 0·25% starch solutions. J. P.

Ferments and Light. V. Diastase. IV. L. Pincussen (*Biochem. Z.*, 1924, **144**, 372—378).—Sodium chloride protects both the diastase and maltase in malt diastase from inactivation by exposure to sunlight. $M/6$-Phosphate solution protects malt diastase and the maltase of " pancreatin Rhenania " from inactivation by ultra-violet light, whilst more dilute phosphate solutions are less effective. Similar results are given by acetate solutions of the same p_H. In the presence of a phosphate buffer, with or without the addition of sodium chloride, the protective action is at a maximum at p_H 6·64. Ammonium, potassium, and lithium chlorides, potassium bromide, and sodium fluoride protect taka-diastase from ultra-violet light to varying degrees, an effect which is more marked in dilute solutions of these salts than in more concentrated solutions. Potassium and sodium nitrates and nitrites give similar results but do not show the same varying effects at different temperatures. J. P.

Purification of Ferments by Electro-dialysis and Electro-Osmosis. I. Malt Diastase. R. Fricke and P. Kaja (*Ber.*, 1924, **57**, [*B*], 310—313).—Electro-dialysis of solutions of malt diastase is effected in a cell divided into three compartments by collodion membranes. The central compartment contains the solution of malt diastase, whilst the outer compartments contain distilled water and the iron gauze cathode and carbon anode, respectively. The voltage used is 220 or 22. As soon as the current has attained a strength of 0·0045—0·006 amp. per sq. cm. the solution in the outer cells is replaced by distilled water and the process is repeated until the current strength remains practically constant at its initial value after recharging the anode and cathode cells. The dry matter concentration of the solution of malt diastase is very considerably lowered, whilst the activity of the enzyme towards starch is increased 2·1 to 2·5 times. After concentration by cautious freezing, the diastase solution gives slight protein but marked carbohydrate reactions. The ash is diminished from 5% to 1%, the nitrogen content from 6·14% to 3·51%.

Electro-osmosis is conducted in a five-compartment cell in which the extreme compartments which contain the electrodes are separated from the intermediate compartments by collodion membranes impermeable to diastase. The barrier between the intermediate and central cells is of collodion permeable to diastase. The central compartment contains the malt diastase solution, the others contain water. The pressure used is 22 volts. After electro-osmosis during 5 days, 39% of the malt diastase remains in the central compartment and shows a diminution in activity from 2·4 to 0·8, 32% has passed towards the anode and is inactive towards starch, 16% has passed towards the cathode and has increased in activity from 2·4 to 4·6, whilst 13% remains in the membranes. The highly active malt diastase gives a marked positive reaction for carbohydrates; it contains carbon 56·4%, hydrogen 7·9%, and nitrogen 3·28%. H. W.

Non-homogeneity and other Properties of Malt Diastase. R. Fricke and P. Kaja (*Ber.*, 1924, **57**, [*B*], 313—316).—A comparison of the starch-liquefying and saccharifying powers of Merck's "diastase absolut" with those of preparations purified by the authors' methods (preceding abstract) shows these properties to be affected to the same degree with respect to soluble starch; the purified product, however, appears to be relatively deficient in starch-liquefying power towards potato starch, thus supporting von Euler's hypothesis ("Chemie der Enzyme," II, 1922, 116) that at least two components are present in malt diastase. The previous conclusion that the presence of proteins in crude malt diastase is not essential to its diastatic properties is strengthened by the observation that the ferment is not affected by prolonged treatment with trypsin. Uranyl acetate is harmless as long as proteins are present with which it forms a precipitate, but after this point is passed, it acts as a vigorous poison. H. W.

Amylolytic and Glycolytic Enzymes of the Pancreas and the Salivary Glands. C. Serono and A. Cruto (*Rass. Clin. Terap. Sci. aff.*, 1923, **22**, 139—142; from *Chem. Zentr.*, 1924, i, 62).—A glycerol extract of pancreas, an aqueous extract of dried sterilised pancreas powder, or salivary diastase, does not form maltose or dextrose from starch solution, but only *iso*maltose. The amount of *iso*maltose formed depends on the concentration of starch. The amylolytic enzyme from pancreas, after separation from lipolytic and proteolytic enzymes, is unstable, but can be stabilised by the addition of plant colloids to the solution. The presence of colloidal material increases the stability to heat of the pancreatic and salivary enzymes. The glycolytic enzyme obtained from the pancreas (Serono and Cruto, *Arch. Farm. Sperim.*, 1913, **14**, 501) is held to be an inner enzyme liberated by maceration, and may be obtained from other tissues in the same way. Only small quantities of ethyl alcohol and carbon dioxide are obtained by its action. It is concluded that no enzyme capable of synthesising sugar occurs in the pancreas. Glycogen is probably formed from *iso*maltose and not from the polymerisation of dextrose. Liver glycogen is only slightly attacked by pancreatic extract under aseptic conditions. G. W. R.

Presence of Inulase in Takadiastase. Y. Takahashi (*Biochem. Z.*, 1924, **144**, 199—202).—Takadiastase contains an inulase capable of hydrolysing inulin to lævulose. J. P.

Inulin and Inulase. IV. H. Pringsheim and G. Kohn (*Z. physiol. Chem.*, 1924, **133**, 80—96).—When inulin is heated in glycerol it is "dissociated" into polymers which consist of 8—10 monoses. Such "dissociated" inulin gradually acquires the properties of "associated" inulin when in solution and eventually separates out as such. The most favourable reaction for the action of inulase on inulin is p_H 3·8, and the hydrolysis proceeds according to the formula of a unimolecular reaction.

Press juices of inulase obtained from older moulds (*Aspergillus niger*) were more active than those derived from younger moulds. The reaction constants have been worked out for inulins of various degrees of purity and for "dissociated" inulin (obtained by heating inulin in glycerol). Invertase hydrolyses inulin and "dissociated" inulin at a hydrogen-ion concentration of the order of that of gastric juice. *Aspergillus niger* contains an invertase as well as an inulase. S. S. Z.

Polysaccharides. XXII. Lichenase and Reserve Cellulose (Lichenin). P. KARRER, M. STAUB, A. WEINHAGEN, and B. JOOS (*Helv. Chim. Acta*, 1924, 7, 144—154).—Lichenin, which has already been recognised as a form of cellulose (A., 1923, i, 1182), is now identified with so-called reserve cellulose. It follows that the enzyme lichenase is closely related to cytase. Since the latter, however, contains enzymes which attack not only reserve celluloses but mannan and galactan, the term lichenase is retained for the enzyme obtained from the snail, *Helix pomatia*. The crude snail extract contains, besides lichenase, a variety of other enzymes, including invertase, lipase, diastase, inulase, maltase, and a cellobiase. The lichenase can be purified from the accompanying enzymes by dialysing, since all of them, with the exception of cellobiase, are unstable in water and quickly disappear. Some of the lichenase is lost during the purification, since it can diffuse through a membrane. The lichenase is best isolated by precipitation from the dialysed solution with acetone. The enzyme rapidly loses its activity if heated above 36°. The most active lichenase preparations are those which have not passed through a drying stage. Basic aluminium sulphate adsorbs lichenase almost completely from neutral solution; the enzyme can be brought into solution again by potassium dihydrogen phosphate and the solution so obtained can be purified by dialysis. Aluminium hydroxide also adsorbs the enzyme completely, but recovery is not so good as from the basic sulphate. The activity of lichenase solutions is not affected by sodium chloride, albumin, or soap, but is lowered by all sugars. The work of Pringsheim and Seifert (A., 1923, i, 998) indicates the presence of lichenase in barley, and it appears to be present in many other plants. Plant lichenase is, however, difficult to separate from accompanying enzymes. E. H. R.

Polysaccharides. XXIII. Separation of Lichenase into Constituent Enzymes. P. KARRER, M. STAUB, and B. JOOS (*Helv. Chim. Acta*, 1924, 7, 154—159).—When a snail lichenase preparation is preserved, its activity gradually diminishes in the course of about 14 days by some 30%, and then remains constant for a long period. The change is shown to be due to the disappearance of cellobiase, a constituent enzyme. Whereas fresh lichenase decomposes lichenin or cellobiose completely to dextrose, lichenase which has been preserved only carries the decomposition of lichenin to an intermediate stage, probably to cellobiose.

E. H. R.

Serum Lipase. G. Fanconi (*Fermentforsch.*, 1924, **7**, 307—348).—Some hydrolysis of fats and cholesterol esters is shown to occur in human serum. Since the tributyrinase of serum (the so-called serum lipase) can be extracted in part by fats and lipoids, and since in lipæmic serum the lipolytic activity is less than in that from the fasting animal, it is argued that the tributyrinase is probably identical with the fat-splitting agent of the serum. The view that serum lipase and complement are closely related is not supported by the fact that quinine and atoxyl inhibit the lipolytic activity but not the complement function of serum. The variations in the lipolytic activity of serum in physiological and pathological conditions are described. R. K. C.

Action of Arsenic and Antimony Compounds on the Fermentative Functions of the Organism. II. Action of certain Arsenic and Antimony Preparations on Pepsin. J. A. Smorodincev and N. P. Riabouschinsky (*Biochem. Z.*, 1924, **144**, 26—30).—Sodium and potassium arsenites and arsenates, and potassium antimonyl tartrate retard the action of pepsin on casein, the last-mentioned in $N/50$, the others in $N/40$ solutions. Lower concentrations of these salts from $N/80$ to $N/10240$ have no influence on the activity of pepsin. In contrast to ptyalin (A., 1923, i, 1246), pepsin is not so susceptible to antimony as to arsenic, and is more stable to both types of compound than is the former enzyme. Hydrochloric acid ($N/40$ to $N/1600$) and tartaric acid ($N/10$ to $N/1280$) have no influence on the action of pepsin. J. P.

Adsorption of Trypsin by Filter-paper. Tsou-Hia Hsü (*Biochem. Z.*, 1924, **144**, 303—307).—Trypsin (Merck) is adsorbed from solution by various makes of filter-paper (Schleicher and Schüll, Dreverhoff). The adsorbed enzyme may be partly recovered by washing with dilute sodium hydroxide and with phosphate solutions of p_H 6·6 to 7·6. Washing with acid, sodium carbonate, and ammonia is ineffective. Variations in temperature have little or no effect on the extent of the adsorption. J. P.

Influence of Colloids on Enzymes. III. I. Hagihara (*Biochem. Z.*, 1924, **144**, 482—489).—Cholesterol has no influence on the action of trypsin at the hydrogen-ion concentration range p_H 5·3—p_H 10·6. Lecithin, on the other hand, stimulates the action of the enzyme in proportion to the quantity present. This stimulation occurs only in alkaline solutions, being entirely absent at or below p_H 6·8; it reaches its maximum at p_H 7·6 and falls in more alkaline solutions. S. S. Z.

Kinetics of Trypsin Digestion. I. Experimental Evidence Concerning the Existence of an Intermediate Compound. J. H. Northrop (*J. Gen. Physiol.*, 1924, **6**, 239—243).—If, as has been suggested, a compound is formed between trypsin and its substrate, the presence of gelatin should decrease the rate of hydrolysis of casein, but this was found not to be the case. This result cannot be explained on the hypothesis that different enzymes in the trypsin act on the two proteins, since the presence of casein, or of gelatin, inhibits the heat-inactivation of the gelatin-hydrolysing power, or of the casein-hydrolysing power, respectively, of the trypsin used (Fairchild's). W. O. K.

Test for Diffusible Ions. I. Ionic Nature of Trypsin. J. H. NORTHROP (*J. Gen. Physiol.*, 1924, **6**, 337—347).—The ratio of the concentrations of trypsin inside and outside the particles of gelatin suspended in water, is equal to the ratio of the hydrogen-ion concentrations on the two sides between the limits of p_H 2 to 10·2. Above p_H 10·2 the trypsin is distributed in the same ratio as the chlorine ion. Trypsin would therefore appear to be a diffusible amphoteric electrolyte, with isoelectric point at p_H 10·2, giving positive univalent ions below this value and negative univalent ions above it, and to be distributed on the two sides of the surface of the gelatin particles in accordance with the Donnan equilibrium. It would seem to be a strong base below p_H 10·2, as no evidence was obtained of undissociated trypsin. With increasing salt content, the same relations in the concentrations hold. The ratios of the concentrations of trypsin, and of hydrogen- and chlorine-ions all change in accordance with the Donnan equilibrium. W. O. K.

[**Pancreatic Enzymes. V.** R. WILLSTÄTTER and collaborators.] **Enterokinase and the Tryptic Action of the Pancreas.** E. WALDSCHMITZ-LEITZ (*Z. physiol. Chem.*, 1924, **132**, 181—237).—A detailed investigation of the influence of enterokinase on the tryptic hydrolysis of gelatin in which the tryptic activity was determined by a method based on that of Willstätter and Waldschmitz-Leitz (cf. A., 1922, ii, 169). The activation of trypsinogen by the kinase is, in its initial stages, proportional to the time and reaches a constant value, less than the maximum possible degree of activation, in from 30 to 60 minutes according to the amount of kinase present. The speed of activation is greatest in neutral solutions. For any given preparation there is a direct proportionality between the amount of kinase necessary for the final degree of activation attained, and the amount of the enzyme activated. Glycerol and ethylene glycol and substances of autolytic origin have an inhibiting effect on the activation. The preparation of purified enterokinase free from proteolytic enzymes is described. Such preparations are highly specific and have no influence on pancreatic lipase or diastase. The author interprets his results as pointing to a simple activation of trypsinogen by the kinase, and as opposing the view that the process is an enzymic one. Using alumina as adsorbent, it is possible to separate the enzyme and its activator and so convert an active trypsin preparation into an inactive trypsinogen, which may then be subsequently reactivated. The trypsinogen of fresh or dried pancreas becomes "spontaneously" activated on keeping, especially in acid solution. This is regarded not as an autolytic change of the inactive enzyme, but as analogous to the activation by enterokinase, since, like the latter, the substance responsible for the phenomenon may be adsorbed by alumina and so separated from an active trypsin which is thus reconverted to trypsinogen. The possible identity of this "spontaneous" activator with enterokinase is discussed in relation to the secretion of active pancreatic juice under the influence of pilocarpine and peptone. It is concluded that the activation of trypsinogen by enterokinase is a specific reaction conditioned in part by adsorption, but chiefly by the mutual influence of enzyme and activator on the affinities of specific groups, which is likened to the effect of hydrogen-ion concentration. J. P.

Arginase in Bacteria. S. HINO (*Z. physiol. Chem.*, 1924, **133**, 100—115).—Living *Bacillus pyocyaneus* and *B. fluorescens*, as well as their acetone preparations, act on *d*-arginine. Filtrates from their cultures were inactive. The arginase is more active in the living organisms. The presence of urease in the above organisms has also been established. *Staphylococci*, *B. prodigiosus*, *B. coli*, *B. paratyphosus*, *B. typhosus*, *B. dysenteriæ* (Shiga), and *Streptococci* do not contain arginase. S. S. Z.

Preparation of Dried Urease and Determination of Urea in Normal and Pathological Urines. G. REVOLTELLA (*Biochem. Z.*, 1924, **144**, 229—257).—Improvements are given in the method already described by the author (*ibid.*, 1922, **134**, 336) for preparing dried urease from soya beans. A correction factor of 5·3% must be added to the urea determined by means of urease prepared by the author's old method in view of the incomplete nature of the conversion of urea to ammonium carbonate. Two improved methods for determining urea are described. In the direct method, 5 c.c. of urine and 2 drops of 0·3% methyl-orange are placed in each of two 50-c.c. graduated flasks, and 0·05*N*-sulphuric acid is added until the colour is light orange; 0·25—1·0 g. of urease (according to the activity of the preparation) is added, the solutions are diluted to 50 c.c. with distilled water, and the flasks are stoppered and placed in a water-bath for 1 hour at 45—50°. Ten c.c. of solution from one flask are titrated against 0·05*N*-sulphuric acid to a light orange and the number of c.c. of acid required multiplied by 0·15525 gives the corrected urea content in grams per 100 c.c. The second flask serves as a control on the completion of the fermentation. An improved direct aspiration method for determining the preformed ammonia and urea in urine or in any body fluid is also given, for details of which the original must be consulted. The influence of various normal and pathological constituents of urine, such as uric acid, proteins, amino-acids, dextrose, sodium chloride, and ammonium carbonate, and of varying conditions of temperature, hydrogen-ion concentration, and light, on the urease method of determining urea has been studied. It is concluded that urease methods provide, when properly controlled, the most convenient and most accurate means of determining urea. J. P.

Auxoureases. F. DI RENZO (*Biochem. Z.*, 1924, **144**, 298—302).—Preliminary heating of a solution of urease for periods varying from 10 to 30 minutes increases the activity of the enzyme, the maximum effect being attained with temperatures of 60—70° using 0·3% solutions of urease. The phenomenon is regarded as being similar to the activating effect of "auxo" bodies such as potassium cyanide and glycine on urease. J. P.

Sulphatase. IV. Enzymic Fission of β-Naphthyl Hydrogen Sulphate. J. NOGUCHI (*Biochem. Z.*, 1924, **144**, 138—140).—β-Naphthyl potassium sulphate was prepared by treating β-naphthol in the presence of pyridine with chlorosulphonic acid dissolved in chloroform, followed by removal of the solvents and neutralisation with potassium hydroxide. The potassium salt, obtained as fine white plates, gave no precipitate in aqueous solution with barium chloride. On incubation with sulphatase (A., 1923, i, 1148; 1924, i, 107), it is hydrolysed to β-naphthol and potassium sulphate.
J. P.

Acid Production by *Bac. Granulobacter*. H. B. SPEAKMAN. —(See i, 371.)

Isoelectric Points for the Mycelium of Fungi. W. J. ROBBINS (*J. Gen. Physiol.*, 1924, **6**, 259—271; cf. *Amer. J. Bot.*, 1923, **10**, 412).—Mycelia of *Rhizopus nigricans* and of *Fusarium lycopersici* behaved towards acid and basic dyes similarly to amphoteric colloids with isoelectric points p_H 5·0 and 5·5 respectively. The amount of growth of *Rhizopus nigricans* on potato-dextrose agar and also the dry matter produced when grown on potato-dextrose broth, when plotted against the p_H of the medium, show a double maximum with an intervening minimum at initial p_H 5·2. W. O. K.

Assimilation of Aldehydes by Plants. II. Polymerisation of Formaldehyde by *Phaseolus multiflorus* and *Pelargonium* with the Formation of Higher Aldehydes. T. SABALITSCHKA and H. RIESENBERG (*Biochem. Z.*, 1924, **144**, 545—550).—The above plants assimilate formaldehyde in the dark with the formation of sugar and starch. S. S. Z.

Assimilation of Aldehydes by Plants. III. Does the Presence of Formaldehyde interfere with the Determination of Sugar and Starch in the Experimental Plants of T. Sabalitschka? T. SABALITSCHKA and H. RIESENBERG (*Biochem. Z.*, 1924, **144**, 551—555).—It does not. S. S. Z.

Respiratory Quotient of Roots and its Variation with the Development of the Plant. R. CERIGHELLI (*Compt. rend.*, 1924, **178**, 645—647).—The respiratory quotient for the detached roots of various plants has been determined at different periods of growth. It was always found to be less than unity at the beginning of growth, and with annuals poor in reserve materials (wheat, maize, etc.), it remains so throughout the whole of the growth period. These two facts are the reverse of those observed in the case of the leaves.

As previously found, the respiratory quotient often falls at the time of flowering or of fruit-bearing, or at some time after this. The root in this case behaves analogously to the leaves.

Annuals possessing plentiful reserve materials (radish, lupin, etc.) and most perennials (iris, rhubarb, etc.) give a respiratory quotient greater than unity, except at the beginning of the growth period. E. E. T.

Effect of Phosphates on [Plant] Respiration. C. J. LYON (*J. Gen. Physiol.*, 1924, **6**, 299—306).—The effect of increasing the phosphate content of the medium upon which *Elodea canadensis* is growing is to increase within about 30 minutes the rate of respiration as measured by the production of carbon dioxide. This effect increases with the concentration of phosphate-ion up to a concentration of $0{\cdot}1M$, beyond which it remains constant. When plotted against time it is found that for any given phosphate concentration the rate of respiration rises to a maximum, falls, rises to a second higher maximum, and again falls. The death of the plant occurs during the fall from the first maximum, the subsequent respiration being a *post-mortem* phenomenon. To investigate the anaërobic respiration wheat seedlings were used, and a similar increase in the production of carbon dioxide in the presence of phosphate was observed. W. O. K.

Development of Pentosans in Barley during Germination. M. H. VAN LAER and A. MASSCHELEIN (*Bull. Soc. chim. Belg.*, 1923, **32**, 402—404).—During the germination process a distinct increase in the quantity of pentosans occurs in barley, especially in the embryo and the radicles. The endosperm also shows an appreciable increase. On steeping in water the total pentosan loss is about 4%; this takes place almost entirely from the chaff. Malting also results in the formation of pentosans, but in this case the distribution is not similar, the increase being considerable in the endosperm, whilst it is very small in the radicles. H. J. E.

Absorption of Carbon by the Roots of Plants. J. F. BREAZEALE (*J. Agric. Res.*, 1923, **26**, 303—311).—Wheat seedlings were grown in a number of different culture solutions, and the plant ashes examined. Carbonates were found in the ash of plants grown in solutions containing sodium or ammonium nitrate, or the carbonates of calcium, sodium, or potassium. The carbonate ion was absorbed by the roots of the plants, but free carbon dioxide could not be taken up in the absence of soluble bases; the rate of absorption of bases depended largely on the absorption of an acid radical. It is suggested that such salts as sodium nitrate influence carbonate absorption as a result of the more rapid removal of the nitrate ion and the subsequent formation of sodium carbonate from atmospheric carbon dioxide. Evidence is advanced that the so-called "lime-loving" plants are in reality those requiring considerable amounts of carbonate. The plant root may maintain equilibrium in its tissues or in the nutrient solution by the intake of carbonate ions or by the excretion of free carbon dioxide. A. G. P.

The Form of Nitrogen most Favourable for Higher Plants. G. Truffaut and N. Bezssonoff (*Compt. rend.*, 1924, **178**, 723—725).—An investigation of the effect of various nitrogenous fertilisers on the growth of several common crops in pots and in the field. It is concluded that mixtures containing nitrogen in the form of carbamide are more effective than nitrates, ammonium salts, or even carbamide alone. In acid soils, carbamide–sodium nitrate mixtures, in alkaline soils, carbamide–ammonium sulphate mixtures, appeared to give the best result. In some cases mixtures of this type have enabled the authors to reduce the percentage of nitrogen in the fertiliser from 3% to 2% and yet to obtain an increased yield. E. E. T.

Influence of a Deficiency of Potash on the Development of Barley Manured with different Amounts of Sodium Nitrate. H. Weissmann (*Z. Pflanz. Düng.*, 1924, **A**, **3**, 21—24).—Barley was grown in sand cultures, with a potash-free nutrient solution, to which increasing amounts of sodium nitrate were added. The dry-weight of the crop decreased with increasing amounts of sodium nitrate, only those plants having the smallest amount of sodium nitrate in the nutrient reaching the grain stage. The other plants died prematurely. The total intake of potassium by the plants decreased with larger doses of sodium nitrate, but the nitrogen- and sodium-intake increased with the proportion of sodium nitrate in the nutrient. The bearing of these results on the influence of potash-starvation on growth (cf. *ibid.*, 1923, **A**, **2**, 1) is discussed. A. G. P.

Coexistence of Starch and Inulin in certain *Compositæ*. L. Daniel (*Compt rend.*, 1924, **178**, 726—727).—Starch and inulin have been found to occur together in *Helianthus tuberosus* and *H. multiflorus* grafted on to the sunflower (annual). On one occasion they were both found in an artichoke graft. They were also found in ungrafted plants, *e.g.*, *Jurinea alata* and various species of *Centaurea*. E. E. T.

State of Tannins in the Vegetable Cell. Michel-Durand (*Compt. rend.*, 1924, **178**, 586—589).—Young oak or chestnut plants, on being extracted with acetone, yield, in general, less tannin than when extracted with boiling water. It is concluded that the tannin is present, in the cell, in more or less intimate combination with mucilaginous substances. E. E. T.

Protopectin and some other Constituents of Lemon Peel. R. Sucharipa (*J. Amer. Chem. Soc.*, 1924, **46**, 145—156).—The author distinguishes between "free pectin," the soluble jelly-making portion of fruits etc.; "protopectin," the water-insoluble pectin occurring in the cell wall closest to the cellulose layer; and "pectic acid," the ultimate product of hydrolysis of pectic substances. Protopectin was prepared from the white pericarp of *Citrus limonum*. It gave pectin and cellulose on hydrolysis besides a small amount of impurities, including lignocelluloses that could not be removed previously. Pectins with different methoxyl contents have been prepared from the same source. It has been shown that the cell-wall of the parenchymatous tissue of *Citrus* contains " free " cellulose, which dissolves readily in Schweitzer's reagent, and also cellulose combined with pectin, which becomes soluble only after hydrolysis. An hypothesis is advanced as to the linking of the cellulose and pectin, based on the replacement of the cellulose in protopectin by methoxyl groups. The question of the transition of protopectin to pectin in the cell is discussed. F. A. M.

Constitution of Derris Root. I. S. Takei (*Rikwagaku Kenkyujo Ihô*, 1923, **2**, 485—496; cf. Kariyone and Atsumi, A., 1923, i, 477).—When extracted with hot ether, roots of *Derris elliptica*, Benth., grown in Singapore, gave colourless, hexagonal plates, m. p. 163°, which correspond with tubatoxin; the formula was found to be $C_{19}H_{18}O_5$, whilst former investigators gave $C_{18}H_{18}O_5$. Its methoxyl content corresponded with 1·5 methoxy groups in 1 mol.; it gave a phenylhydrazone, yellow needles, m. p. 243—245°. For the rabbit, the minimum lethal dose was 0·00125 g. per 100 g. of body-weight. When treated with concentrated sulphuric acid, it was changed into an *isomeride*, colourless needles, m. p. 177—178°, having no poisonous properties. The saponification of tubatoxin with 3% hot alcoholic potash gave a *phenolcarboxylic acid*, $C_{10}H_{10}O_3$, m. p. 128—129°, which absorbed bromine and gave a violet colour with ferric chloride. When the saponification was conducted in a current of hydrogen, an *isomeride*, colourless needles, m. p. 209—210°, was obtained which had no poisonous action. By fusion with potassium hydroxide, tubatoxin itself or the acids mentioned above gave another *phenolcarboxylic acid*, $C_9H_9O_3$, colourless needles, m. p. 182°. This acid sublimed at about 160°, and is probably a methylated benzoic acid. K. K.

Chemical Analysis of *Jatropha stimulosa*. P. Menaul (*J. Agric. Res.*, 1923, **26**, 259—260).—The seeds of *Jatropha stimulosa* resemble castor beans, and contain 61% of kernel. The expressed oil had the following characteristics: $d^{15\cdot6}$, 0·9257; $n^{15\cdot6}$, 1·4765; solidifies below − 15°; iodine number, 124·65—129·47; saponification number, 186; volatile fatty acids, none; free fatty acids, trace; fatty acids, 95·6%; glycerol about 4·2%. The seeds also contain much protein, the analysis and nitrogen distribution of which has been studied. There is a high histidine content. A. G. P.

Mono- and Di-methylolcarbamide. Their Effect on Plant Growth, and their Decomposition in the Soil. E. Blanck and F. Giesecke (*Z. Pflanz. Düng.*, 1923, **2**, 393—420).—When formaldehyde is added as a preservative to liquid manure (urine) containing carbamide, monomethylol carbamide, $CO(NH_2)NH{\cdot}CH_2{\cdot}OH$, and dimethylolcarbamide, $CO(NH{\cdot}CH_2{\cdot}OH)_2$, may be formed. Experiments are described on the effect of these compounds, and also of liquid manure–formaldehyde mixtures, on the growth of plants in sand and soil cultures. Both compounds at first depress the germination of oats and turnips. This effect is, however, followed by stimulation. Monomethylolcarbamide is equally effective with ammonium sulphate as a source of nitrogen for oats and mustard. Dimethylolcarbamide is generally less satisfactory, and may in some cases be actually harmful. The experiments with liquid manure–formaldehyde mixtures show similar results, large amounts of formaldehyde being injurious. The nitrogen of these compounds is readily ammonified by soil organisms. It is concluded that whilst formaldehyde may be used as a preservative with liquid manure, excess should be avoided. G. W. R.

Nature of the Activity of the Colloidal Clay of Acid Soils. R. Bradfield (*J. Amer. Chem. Soc.*, 1923, **45**, 2669—2678).—In this investigation, standard solutions of sodium hydroxide and calcium hydroxide were titrated with the colloidal material from four acid soils and the end-points determined by both conductivity and hydrogen-ion concentration measurements (cf. *ibid.*, 1923, **45**, 1245). The end-points found by both methods were fairly definite, and the titration curves were of the type commonly obtained in the titration of a strong base by a weak acid. The same amounts of the colloidal acids were required to neutralise equivalent quantities of the two bases, and definite breaks were obtained in the conductivity curves, indicating the neutralisation of definite acids. The reaction between acid colloidal clays and strong bases appears to be an ordinary neutralisation. The results obtained tend to show that the colloidal material of an acid soil is itself an acid which ionises to produce a definite Sörensen value and which shows a definite titrable acidity on titration with strong bases. F. G. P.

Soil Reaction in Relation to Calcium Adsorption. C. O. Swanson (*J. Agric. Res.*, 1923, **26**, 83—121).—The adsorption of calcium and the alterations in soil reaction, following the addition of lime to a number of soils, are described. Potassium chloride was found to reduce the adsorption of calcium in soils unless relatively large amounts of calcium carbonate were present. Soil suspensions showed lower p_H values than filtered soil extracts. The adsorption of calcium by soils was more intimately connected with the clay content than with the original hydrogen-ion concentration of the soil. Fuller's earth had a greater hydrogen-ion concentration and a greater adsorptive power than any soil examined. Leaching with water did not affect the adsorptive power or p_H value of soils. The presence of calcium carbonate did not influence the calcium adsorption from calcium hydroxide. Dilute hydrochloric acid increased the hydrogen-ion concentration of soils to an extent proportional to the amount of acid. Small additions of oxalic acid to soil decreased the hydrogen-ion concentration and larger amounts increased this figure, but to a less extent than did equivalent quantities of hydrochloric acid. Acidity of mineral soils is attributed to the leaching out of bases leaving acid alumino-silicates, which readsorb soluble bases (particularly calcium), leaving an insufficient supply for the normal growth of plants. A new apparatus for determining hydrogen-ion concentrations of soils is described. A. G. P.

Partial Sterilisation of Soil by Antiseptics. (Mrs.) A. Matthews (*J. Agric. Sci.*, 1924, **14**, 1—57).—An examination is recorded of the microflora in soils treated with a number of organic antiseptics. The normal effect of antiseptics—an initial decrease in bacterial numbers followed by a sudden rise, which was maintained for varying periods and finally tended to return towards normal—was observed. The antiseptics disappeared from the soil fairly quickly. Aëration increased the rapidity of these changes. The extent of the increase in bacterial numbers varied according to the molecular weight and heat of combustion of the antiseptics used, and some correlation with the latter factor is indicated. Bacterial changes seemed in no way connected with protozoa and occurred in a normal manner even in protozoa-free soils. Increases in bacterial population are ascribed to the feeding effect of the antiseptics or the bacteria, and the improved fertility following partial sterilisation to the breaking down of soil organic matter by the increased number of organisms. The action of lime and of steaming in increasing the bacteria is assumed to result from improved conditions, due to the breaking down of plant residues, etc. Aliphatic compounds produce quicker but smaller changes than aromatic ones. Among aromatic compounds, the introduction of the $-CH_3$ group into the benzene ring lessened the toxicity of the compound to soil organisms, whereas $-Cl$ and $-NO_2$ produced increased toxicity and stability in the soil. The toxic effects of a number of antiseptics on protozoa, eelworm, and fungi are recorded.

A. G. P.

The Manurial Properties of Lead Nitrate. R. A. Berry (*J. Agric. Sci.*, 1924, **14**, 58—65).—A number of culture and field experiments are described in which lead nitrate was used as the source of nitrogen to plants, in comparison with sodium nitrate. Similar yields were obtained by both treatments. The lead salt tended to produce plants with wider leaf blade and of slightly darker colour. When used in commercial quantities, no lead was found in the plants produced, nor could any be leached from the soil. Except when high concentrations were used, lead was adsorbed and rendered non-toxic by the soil. It would appear probable that lead salts increased the rate of nitrification in soils.

A. G. P.

Action of Sodium Nitrite in the Soil. R. H. Robinson (*J. Agric. Res.*, 1923, **26**, 1—7).—Experiments are described demonstrating the unsuitability of sodium nitrite as a fertiliser, particularly on acid soils. In all soils examined, there was a steady loss of nitrogen from the nitrite, only a small proportion of which became oxidised to nitrate. This loss was much accelerated in acid soils. The addition of lime or calcium carbonate to such soils retarded the decomposition of nitrites, but no increased nitrate content could be observed.

A. G. P.

Organic Chemistry.

Silver-sulphochromic Oxidation of Coal. L. J. Simon (*Compt. rend.*, 1924, **178**, 775—777).—When coal is heated with a mixture of silver dichromate and concentrated sulphuric acid at 100°, 4—5% of the carbon present remains unoxidised. Formation of gaseous oxidation products is more rapid at 50° than at 60°, at which temperature 28% of the coal remains unchanged, about 6·7% being rendered soluble. When powdered coke is oxidised by chromic acid, 54·2% is unaffected, as against 39% when silver dichromate is used. It is concluded from the results that coal contains two constituents intimately mixed. One is oxidised at low temperatures, the other, like coke, requiring a temperature of 100°. E. E. T.

Composition of Natural Gas Gasoline. R. P. Anderson and A. M. Erskine (*J. Ind. Eng. Chem.*, 1924, **16**, 263—267).—Fractional distillation shows that the approximate composition of this gasoline is: propane and butanes, 20% (by volume); *iso*pentane, 13%; *n*-pentane, 17%; *iso*hexane, 9%; *n*-hexane, 15%; *iso*heptane, 8%; *n*-heptane, 12%; octane, 4%, and absorption oil, 2%; the presence of traces of benzene and toluene is indicated. C. I.

Composition of Low-temperature Tar. IV. F. Schütz, W. Buschmann, and H. Wissenbach (*Ber.*, 1924, **57**, [*B*], 421—423; cf. A., 1923, i, 1080).—An examination of the requisite C_9 to C_{12} fraction of neutral oil from low-temperature coal-tar showed that 80—86% consists of unsaturated and aromatic hydrocarbons, whilst the remaining 14—20%, boiling from 30° to 220°, probably contains *n*-nonane, *n*-decane, *n*-undecane, and *n*-dodecane, as indicated by the boiling points of the fractions, although the densities are slightly too high. [Cf. *B.*, 1924, 367.] F. A. M.

Action of Sodamide on True Acetylene Hydrocarbons. Bourguel (*Compt. rend.*, 1924, **178**, 777—779; cf. A., 1923, i, 1176).—When chloro-compounds are treated, by the author's method, with sodamide, the acetylene hydrocarbon is never present as such at the end of the reaction, but as a sodamide or sodium derivative of the hydrocarbon. If pure pentinene, diluted with xylene, is added to a xylene suspension of sodamide heated at 120°, 1 mol. of ammonia is evolved per mol. of pentinene, with formation of a sodium derivative of the latter. E. E. T.

Chlorination of Butylene and the Properties of Dichlorobutane. E. Briner, J. Hausser, and E. de Luserna (*Helv. Chim. Acta*, 1924, **7**, 374—376).—*n*-Butyl alcohol is readily converted into butylene by passage over alumina at 480°. Butylene combines with chlorine, with evolution of heat, forming dichlorobutane, the molecular heat of reaction being 33·4 Cal. The reaction is not explosive. Dichlorobutane has b. p. 114·6—114·8°/730 mm.; n^{20} 1·4325; d^{0} 1·144, $d^{22\cdot2}$ 1·115, $d^{99\cdot5}$ 1·032; ignition temperature, 62°. The viscosity coefficient is 0·0515 at 0°, 0·01073 at 22·2°, 0·00535 at 99·5°. It is a good solvent for oils and fats and is not poisonous. E. H. R.

Action of Ammonia on Organic Halogen Compounds at High Temperature. J. Heslinga (*Rec. trav. chim.*, 1924, **43**, 178—180).—The halogen in organic compounds containing chlorine or bromine is quantitatively converted into ammonium halide when the substance is heated to redness in a current of ammonia. Chloro derivatives of benzene, if substituted in the ring, are exceptions to the general rule. (Cf. this vol., ii, 55.) H. J. E.

Near Ultra-red Absorption Spectra of some Organic Liquids. J. W. Ellis.—(See this vol., ii, 218.)

Analogues of Citronellol Richer and Poorer in Carbon. I. J. von Braun and R. Gossel (*Ber.*, 1924, **57**, [*B*], 373—382).—The effect of the position of the double bond and of the number and position of the methyl groups on the odour of citronellol, $CMe_2{:}CH\cdot[CH_2]_2\cdot CHMe\cdot CH_2\cdot CH_2\cdot OH$, has been examined. The conversion of the terminal group, $CMe_2{:}C-$, into the complex, $CH_2{:}C-$, causes a very marked alteration in odour which is less marked when the group is $CHMe{:}C-$; the introduction of further methyl radicals (in addition to the γ-methyl group) does not cause an appreciable change in odour, whence it is probable that the γ-methyl group is itself unimportant. The decisive factor appears to be the presence of the group $CMe_2{:}C-$, or to a less extent of $CHMe{:}C-$, at a definite distance from the primary alcoholic group. The alcohols described in the present communication are optically inactive, but the comparison of them with optically active citronellol is regarded as justifiable, since, in general, little difference in odour is observed between isomeric active and racemic substances.

Δ^{β}-Butenyl bromide reacts readily with an alcoholic solution of ethyl sodioacetoacetate to give a mixture of *ethyl butenylacetoacetate*, $CH_3\cdot CO\cdot CH(CH_2\cdot CH{:}CHMe)\cdot CO_2Et$, a mobile liquid, b. p. 112—114°/11 mm., and *ethyl dibutenylacetoacetate*, b. p. 135—137°/12 mm. The former ester is hydrolysed by dilute, aqueous potassium hydroxide solution to *Δ^{β}-heptene-ζ-one*, $CHMe{:}CH\cdot[CH_2]_2\cdot COMe$, b. p. 152—155°/atmospheric pressure, 42—43°/9 mm., d_4^{20} 0·8446, n_D^{20} 1·4292 (*semicarbazone*, lustrous leaflets, m. p. 97°). *Ethyl methylbutenylacetoacetate*, $CH_3\cdot CO\cdot CMe(CH_2\cdot CH{:}CHMe)\cdot CO_2Et$, b. p. 120—122°/20 mm., is hydrolysed to *γ-methyl-Δ^{ϵ}-heptene-β-one*, $CHMe{:}CH\cdot CH_2\cdot CHMe\cdot COMe$, b. p. 62—64°/20 mm., d_4^{18} 0·8463, n_D^{18} 1·4345, which resembles amyl acetate in odour.

Ethyl β-methyl-$\Delta^{\alpha\epsilon}$-heptadienoate, a colourless liquid, b. p. 103—105°/22 mm., prepared by the action of potassium hydrogen sulphate at 150° on ethyl β-hydroxy-β-methyl-$\Delta^{\alpha\epsilon}$-heptadienoate, is reduced by sodium and alcohol to *γ-methyl-Δ^{ζ}-heptenol*,

$$\mathrm{CH_2{:}CH\cdot[CH_2]_2\cdot CHMe\cdot CH_2\cdot CH_2\cdot OH},$$

b. p. 97—99°/22 mm., d_4^{19} 0·8562, n_D^{19} 1·4470, which has no resemblance in odour to citronellol.

Δ^{β}-Hexene-ζ-one is transformed by zinc and ethyl α-bromopropionate into *ethyl β-hydroxy-αβ-dimethyl-Δ^{ϵ}-heptenoate*,

$$\mathrm{CH_2{:}CH\cdot[CH_2]_2\cdot CMe(OH)\cdot CHMe\cdot CO_2Et},$$

a somewhat viscous, colourless, odourless liquid, b. p. 124—126°/18 mm., which is hydrolysed to the corresponding *acid*, a colourless, viscous liquid with a very unpleasant odour, b. p. 175—176°/18 mm. The latter compound is converted by acetic anhydride and anhydrous sodium acetate into *αβ-dimethyl-$\Delta^{\alpha\epsilon}$-heptadienoic acid*,

$$\mathrm{CH_2{:}CH\cdot[CH_2]_2\cdot CMe{:}CMe\cdot CO_2H},$$

an unpleasant smelling liquid, b. p. 145—146°/18 mm., from which *ethyl αβ-dimethyl-$\Delta^{\alpha\epsilon}$-heptadienoate*, b. p. 103—105°/18 mm., is prepared. The ester is reduced by sodium and alcohol to *βγ-dimethyl-Δ^{ζ}-heptenol*, $\mathrm{CH_2{:}CH\cdot[CH_2]_2\cdot CHMe\cdot CHMe\cdot CH_2\cdot OH}$, b. p. 101—102°/20 mm., d_4^{21} 0·8741, n_D^{21} 1·4570, the odour of which is quite distinct from that of citronellol.

Ethyl β-hydroxy-αβγ-trimethyl-Δ^{ϵ}-heptenoate,

$$\mathrm{CH_2{:}CH\cdot CH_2\cdot CHMe\cdot CMe(OH)\cdot CHMe\cdot CO_2Et},$$

a viscous liquid with a very faint odour, b. p. 123—125°/17 mm., is readily obtained from γ-methyl-Δ^{ϵ}-heptene-β-one, zinc, and ethyl α-bromopropionate. Complete dehydration of this compound or of the corresponding hydroxy acid could not be accomplished. The incompletely homogeneous βγδ-trimethyl-Δ^{ζ}-heptenol,

$$\mathrm{CH_2{:}CH\cdot CH_2\cdot[CHMe]_3\cdot CH_2\cdot OH},$$

does not, however, resemble citronellol in odour.

Ethyl β-hydroxy-β-methyl-Δ^{ϵ}-octenate,

$$\mathrm{CHMe{:}CH\cdot[CH_2]_2\cdot CMe(OH)\cdot CH_2\cdot CO_2Et},$$

b. p. 121—122°/10 mm., is hydrolysed to the corresponding *acid*, a viscous liquid, b. p. 177—180°/16 mm., which is transformed by sodium acetate and acetic anhydride into *β-methyl-$\Delta^{\alpha\epsilon}$-octadienoic acid*, $\mathrm{CHMe{:}CH\cdot[CH_2]_2\cdot CMe{:}CH\cdot CO_2H}$, b. p. 149—150°/18 mm., from which *ethyl β-methyl-$\Delta^{\alpha\epsilon}$-octadienoate*, b. p. 114—115°/18 mm., is obtained. The ester is readily reduced by sodium and alcohol to *γ-methyl-Δ^{ζ}-octenol* (*norcitronellol*),

$$\mathrm{CHMe{:}CH\cdot[CH_2]_2\cdot CHMe\cdot CH_2\cdot CH_2\cdot OH},$$

b. p. 109—111°/20 mm., d_4^{20} 0·8674, n_D^{20} 1·4560, which has a terpene-like odour with a faint resemblance to that of citronellol. β-*Methyl-Δ^{ϵ}-octenoic acid*, $\mathrm{CHMe{:}CH\cdot[CH_2]\cdot CHMe\cdot CH_2\cdot CO_2H}$, b. p. 145—146°/18 mm., is obtained as by-product of the reduction; the corresponding *ethyl* ester has b. p. 109—111°/21 mm.

Ethyl β-hydroxy-αβ-dimethyl-Δ^{ϵ}-octenoate,

$$\mathrm{CHMe{:}CH\cdot[CH_2]_2\cdot CMe(OH)\cdot CHMe\cdot CO_2Et},$$

b. p. 139—142°/20 mm., is converted by potassium hydrogen sulphate into *ethyl αβ-dimethyl-$\Delta^{\alpha\epsilon}$-octadienoate*,

$$\mathrm{CHMe{:}CH\cdot[CH_2]_2\cdot CMe{:}CMe\cdot CO_2Et},$$

a liquid with a tolerably pleasant odour, b. p. 115—116°/19 mm., and the corresponding *acid*, an unpleasant smelling liquid, b. p.

152—155°/20 mm. The ester is reduced by sodium and alcohol to *βγ-dimethyl-Δ^{ζ}-octenol*, $CHMe\colon CH\cdot[CH_2]_2\cdot[CHMe]_2\cdot CH_2\cdot OH$, b. p. 111—112°/21 mm., d_4^{21} 0·8775, n_D^{21} 1·4670, which resembles the terpenes and citronellol in odour.

Ethyl β-hydroxy-βγ-dimethyl-Δ^{ϵ}-octenoate,

$$CHMe\colon CH\cdot CH_2\cdot CHMe\cdot CMe(OH)\cdot CH_2\cdot CO_2Et,$$

an odourless liquid, b. p. 137—139°/20 mm., is transformed successively into *ethyl βγ-dimethyl-$\Delta^{\alpha\epsilon}$-octadienoate*, a very pleasant smelling liquid, b. p. 123—124°/20 mm., and *γδ-dimethyl-Δ^{ζ}-octenol*, $CHMe\colon CH\cdot CH_2\cdot[CHMe]_2\cdot CH_2\cdot CH_2\cdot OH$, b. p. 114—115°/17 mm., d_4^{19} 0·8775, n_D^{19} 1·465, which is allied to citronellol in odour.

Methylheptenone, zinc, and ethyl α-bromopropionate yield *ethyl β-hydroxy-αβζ-trimethyl-Δ^{ϵ}-octenoate*,

$$CMe_2\colon CH\cdot[CH_2]_2\cdot CMe(OH)\cdot CHMe\cdot CO_2Et,$$

a colourless, viscous liquid, b. p. 145°/16 mm., which is transformed by potassium hydrogen sulphate at 150° into *ethyl αβζ-trimethyl-$\Delta^{\alpha\epsilon}$-octadienoate*, b. p. 126—128°/20 mm. The latter ester is smoothly reduced to *βγη-trimethyl-Δ^{ζ}-octenol* (*homocitronellol*),

$$CMe_2\colon CH\cdot[CH_2]\cdot[CHMe]_2\cdot CH_2\cdot OH,$$

a mobile liquid, b. p. 125—127°/20 mm., d_4^{17} 0·8860, n_D^{17} 1·4725. The odour of the substance is more closely similar to that of citronellol than are those of the alcohols containing the terminal group, $CHMe\colon C-$. When preserved, it exhibits the same change and refinement of odour which is characteristic of citronellol, and is possibly due to an establishment of an equilibrium between two forms containing the groups, $CMe_2\colon C-$ and $CH_2\colon CMe\cdot C-$. H. W.

Manufacture of Ether. J. DESMAROUX (*Mém. Poudres*, 1923, **20**, 335—390).—The system, $H_2SO_4–EtOH–H_2O–Et_2O–EtHSO_4$, is considered theoretically, and a diagram is evolved showing the interdependence of the concentrations of the various components. Phase-rule considerations show that the system has three degrees of freedom. The state of equilibrium, particularly with regard to ether, is practically independent both of the temperature and of the sulphuric acid concentration. The experimental results obtained are in excellent agreement with the formulæ $Y=m(1-10^{-ht})$ and $X=r(1-S.10^{kt})$ where Y=the percentage of alcohol converted into ether and X=the percentage of free acid in the mixture at the end of time t. Tables giving the values of the constants m, h, r, k, and S for the various temperatures and concentrations of sulphuric acid and alcohol are appended. A comprehensive thermodynamic study of the conditions of the reaction enables results to be deduced which are in general agreement with practical experience of ether manufacture. A laboratory investigation of the nature of the vapour given off showed that with a fall in the acidity of the mixture the quantity of alcohol in equilibrium with it increases and the proportion of ether in the vapour falls. [Cf. *B.*, 1924, 313.] H. C. R.

Termolecular Gas Reactions. I. Mechanism of the Formation of Acetic Acid from Acetaldehyde and Oxygen. A. KISS and L. DEMÉNY (*Rec. trav. chim.*, 1924, **43**, 221—248).—The reaction between pure acetaldehyde and pure oxygen was examined by the method previously described (A., 1923, ii, 237), the theory developed by Trautz (A., 1918, ii, 151) being applied. If the formation of an intermediate compound, $CH_3 \cdot CHO,O_2$, is postulated: $CH_3 \cdot CHO + O_2 = CH_3 \cdot CHO,O_2$; $CH_3 \cdot CHO,O_2 + CH_3 \cdot CHO = 2CH_3 \cdot CO_2H$, the velocity constant passes through a maximum with lapse of time, which suggests catalytic action. The reaction was also studied in presence of water vapour. At 20°, a long period of induction (10 hours) set in; at 60—80°, the induction period was shorter than for the dry gases at the same temperatures. These results showed that the action was autocatalytic, the formation of the autocatalyst being accelerated by moisture. The experimental results did not indicate whether the catalysis was chemical or physical. The autocatalyst is probably acetic acid: $CH_3 \cdot CHO + CH_3 \cdot CO_2H \rightleftharpoons CH_3 \cdot CHO,CH_3 \cdot CO_2H$ (infinitely rapid); $CH_3 \cdot CHO,CH_3 \cdot CO_2H + O_2 = CH_3 \cdot CO_2H + CH_3 \cdot CHO,O_2$ (measurable speed). The formation of this intermediate compound was shown to be a true gas reaction of the second order, catalysed by acetic acid but uninfluenced by water. With increasing oxygen pressure, the reaction is retarded; excess of aldehyde accelerates it, which seems to point to the complex $CH_3 \cdot CHO,CH_3 \cdot CO_2H$ as the catalyst. Indifferent gases (nitrogen, carbon dioxide) exerted no influence, neither, apparently, did the surface of the containing vessel. The reaction was not sensitive to light. S. K. T.

Ammonium Oleate. M. MLODZIEJEVSKI (*J. Russ. Phys. Chem. Soc.*, 1915, **47**, 471—478).—Ammonium oleate when gently heated with alcohol dissolves, and on cooling crystallises in the form of plates possessing double refraction. When it is heated more strongly and then allowed to cool, a fine emulsion possessing double refraction is formed. This is followed by the appearance of fluid crystals in the form of "puppets" and sometimes also liquid spherolites and oily strips. On further cooling, the liquid crystals disappear; an emulsion is temporarily formed which is then followed by the appearance of the solid crystals. The same changes can be studied repeatedly on a single microscopic slide. S. P. S.

Simple and Mixed Acid Anhydrides. W. AUTENRIETH and G. THOMAE (*Ber.*, 1924, **57**, [*B*], 423—437; cf. A., 1901, i, 185).—It is shown that it is not possible to prepare mixed aliphatic–aromatic or aromatic–aromatic anhydrides either by the action of acetic anhydride on aromatic acids or by the action of the acid chloride on the sodium salt of another acid. The reaction given in Beilstein's "Handbuch" (3 *Aufl.*, **1**, 461): $(C_2H_3O)_2O + 2C_2H_5 \cdot OH = 2C_2H_3O_2 \cdot C_2H_5 + H_2O$, is shown to be incorrect, as in all cases examined 1 mol. of anhydride yielded only 1 mol. of ester and 1 mol. of free acid.

Ammonia, phenylhydrazine, and aniline react with aromatic anhydrides to give 1 mol. of free acid and 1 mol. of the acid amide, anilide, or hydrazide. Hydrazine hydrate reacts with *p*-toluic anhydride to give *s*-di-*p*-toluoylhydrazine, whilst a 50% aqueous solution of the base yields the monoacyl derivative,

$$C_6H_4Me \cdot CO \cdot NH \cdot NH_2.$$

p-Bromobenzoic anhydride yields only p-*bromobenzoylhydrazine*, m. p. 167°. The following anhydrides were prepared by the action of acetic anhydride on the requisite acid: stearic anhydride, m. p. 70—71°; palmitic anhydride, m. p. 62—63°; phenylacetic anhydride, prisms, m. p. 71—72°; *o*-toluic anhydride, m. p. 38—39°; m-*toluic anhydride*, prisms, m. p. 70—71°; *p*-toluic anhydride, leaflets, m. p. 95°; *p*-bromobenzoic anhydride, white plates, m. p. 218°; m-*nitrobenzoic anhydride*, prisms, m. p. 159—160°; p-*ethoxybenzoic anhydride*, m. p. 108° (which yields with aniline p-*ethoxybenzanilide*, m. p. 169°). The following new compounds are also noted: *Phenyl phenylacetate* (from phenylacetic anhydride and phenol), prisms, m. p. 42°. p-*Tolyl phenylacetate*, prisms, m. p. 75—76°. p-*Tolyl* p-*toluate* (from *p*-toluic anhydride and *p*-cresol), plates, m. p. 91—92°. F. A. M.

The Influence of Constitution on the Catalytic Hydrolysis of Esters by Acids. G. BERGER (*Rec. trav. chim.*, 1924, **43**, 163—177).—The rate of hydrolysis of about twenty esters of monobasic fatty acids and of substituted acetic and benzoic acids was studied. The catalyst used was *N*/10-hydrochloric acid and the medium of hydrolysis a mixture of alcohol and water containing 42·34% of alcohol. Experiments were carried out at different temperatures owing to the variation in ease of hydrolysis shown by the esters, and in calculating the reaction-velocity the presence of ethyl alcohol as solvent was recognised as a factor in the case of ethyl esters. The author draws the conclusions that the acceleration of hydrolysis brought about by hydrogen ions decreases with the strength of the ester acid (cf. Olivier and Berger, A., 1923, ii, 144) and, in the case of esters with negative alcoholic groups, *i.e.*, where the alcoholic constituent possesses a somewhat acid character, the acceleration is small. In the case of methyl and ethyl esters of the same acid, the difference in reaction velocity is not constant but decreases with the acidity of the ester. The accelerated action in the case of an ester of the type $R'\cdot CO_2R''$ is thus conditioned by both the R′ and R″ groups, and these groups appear to be of equal importance and strength in their influence on hydrolysis from both the qualitative and quantitative points of view. H. J. E.

Monocarboxylic Acids derived from Sugars. II. Methylation of Tetramethyl-gluconic Acid. J. PRYDE (*J. Chem. Soc.*, 1924, **125**, 520—522).—Tetramethyl-gluconolactone, treated with one molecular proportion of water, and then with methyl iodide and silver oxide at 40°, yields *methyl tetramethyl-gluconate*, $OMe\cdot CH_2\cdot CH(OMe)\cdot CH(OH)\cdot[CH(OMe)]_2\cdot CO_2Me$, a neutral, mobile oil, n_D^{15} 1·4480. On subjecting this to five successive methylations, *methyl pentamethyl-gluconate* was obtained as a neutral, colourless, limpid, very mobile oil, b. p. 100°/1·0 mm., n_D^{15} 1·4412, $[\alpha]_{5461}$ +42·7° in alcohol, and +24·9° in water, falling to +21·9° in 4 months. F. G. W.

Oils in the Chaulmoogra Group. G. A. PERKINS and A. O. CRUZ (*Philippine J. Sci.*, 1923, **23**, 543—569).—The oils from the seeds of the following species were examined: *Gynocardia odorata, Hydnocarpus alcalæ, H. anthelminthica, H. Hutchinsonii, H. subfalcata, H. venenata, H. Wightiana, H. Woodii, Pangium edule,* and *Taraktogenos Kurzii.* The data obtained show a close similarity between the true chaulmoogra oil (from *Taraktogenos Kurzii*) and all the *Hydnocarpus* oils investigated. The oil from *Hydnocarpus alcalæ* is distinguished by its very high content of chaulmoogric acid. It contains little or no hydnocarpic acid. The other *Hydnocarpus* oils, like chaulmoogra oil, may each be separated by the distillation of the ethyl esters into fractions, one of which contains the acids with 16 carbon atoms and the other those with 18 carbon atoms. The former fractions of each oil contain hydnocarpic acid and an unknown acid or acids which cannot be completely separated from the hydnocarpic acid by one recrystallisation from 80% alcohol. This unknown acid portion has a lower optical activity than hydnocarpic acid. The latter fractions (acids with 18 carbon atoms) contain chaulmoogric acid, which can be separated more readily than hydnocarpic acid. A more highly unsaturated portion is left in the case of many samples when the chaulmoogric acid is crystallised out. Previous results placing *Gynocardia odorata* outside the chaulmoogra group were confirmed. *Pangium edule* seeds appear to contain no chaulmoogric or hydnocarpic acids. H. C. R.

Compounds Developed in Rancid Fats, with Observations on the Mechanism of their Formation. W. C. POWICK (*J. Agric. Res.*, 1923, **26**, 323—362).—A large number of possible products of rancidity in fats have been examined. It is suggested that nonaldehyde is in part responsible for the odour of rancid fats. The glyceryl radical and the unsaponifiable portion of fats appeared to have no part in the phenomena of rancidity, which may be reproduced by the oxidation of oleic acid. The colour developed in the Kreis test for rancidity was spectroscopically identical with that obtained by applying the test to a mixture of acraldehyde and hydrogen peroxide, and the essential compound appeared to be epihydrin aldehyde. Whilst this compound did not occur in rancid fats, a derivative, probably the acetal, is suggested as being the parent substance which is decomposed on the addition of hydrochloric acid in the Kreis test. A number of substances give a red coloration with phloroglucinol–hydrochloric acid, and spectroscopic examination is necessary to obtain positive evidence of rancidity. A possible mechanism for the formation of epihydrin aldehyde or its parent substance from fats is described. A. G. P.

Reactivity of Iodine towards Fats. III. Production of Acidity in the Reaction and the Mechanism of its Formation. B. M. MARGOSCHES and W. HINNER (*Chem. Umschau*, 1924, **31**, 41—45).—Acids are produced in the reaction between fats or unsaturated fatty acids and iodine solutions, the quantity varying with the solvent used for the iodine. Brown iodine solutions obtained with aqueous solvents or solvents miscible with water, from which an amount of iodine is absorbed by the fat which almost corresponds with its iodine value (Hübl), give a large amount of acid, corresponding with about half the iodine absorbed. Solutions of iodine in carbon tetrachloride, however, produce no acid in their action on fats, and other violet iodine solutions (in benzene, chlorinated ethylenes, and chloroform) give varying but comparatively small amounts of acid when they react on fats. In the action of aqueous and alcoholic iodine solutions on fats, an additive product of hypoiodous acid and the unsaturated molecule is formed, and not a simple iodine additive product as commonly supposed. This view is supported by the qualitative and quantitative production of acid. The action is analogous to Wijs' explanation of the action of his iodine monochloride solution on unsaturated linkings. The iodine from violet iodine solutions is mainly absorbed by unsaturated fats as such, but the reaction does not by any means proceed to completion. In the case of brown iodine solutions, the active mass of the hydrogen iodide formed during the reaction, or added to the solution, opposes itself to the complete addition of hypoiodous acid to the unsaturated linkings, and so reduces the absorption of iodine. H. C. R.

Oxidation of Lumbang and Linseed Oils and of the Principal Compounds in Lumbang Oil. A. P. West and A. I. de Leon (*Philippine J. Sci.*, 1924, **24**, 123—140).—When lumbang and linseed oils are blown under the same conditions at 75°, the percentage of apparent oxygen absorption, volatile products evolved, and total oxygen absorption in the early stages of oxidation are greater for lumbang than for linseed oil. As the oxidation process continues, the velocity of oxygen absorption increases more rapidly for linseed than for lumbang oil until after 100 hours the percentage of total oxygen absorption of linseed is greater than that of lumbang oil. Data giving the total percentage of oxygen absorption per hour during definite periods of time for these two oils indicate that for about the first 30 hours lumbang oil absorbs oxygen much more rapidly than does linseed oil. After 30 hours of oxidation, the rate of absorption of oxygen by lumbang oil gradually decreases, whilst the corresponding rate for linseed oil considerably increases. Both oils have about the same absorption velocity for oxygen for the period of oxidation extending from 30 to 40 hours. In the case of linseed oil, the velocity of oxygen absorption increases continually up to a period of 100 hours, beyond which the oxidation experiments were not continued. Both linseed and lumbang oils contain linolenic, linolic, and oleic glycerides, and also saturated glycerides. Linseed oil contains a much larger percentage of linolenic glycerides and of saturated glycerides than does lumbang oil. Possibly autocatalysts are formed in both these oils during oxidation and tend to accelerate the velocity of oxygen absorption, whilst the saturated glycerides present tend to retard the velocity of absorption. Constants of samples of lumbang and linseed oils blown for various periods of time at 75° were determined. Both oils gave very similar results. The surface tensions and refractive indices of both oils increased slightly on oxidation, whilst the iodine values decreased considerably. Samples of lumbang oil oxidised for various periods of time were analysed. The percentage of oxidised glycerides increased, whilst the percentage of unoxidised unsaturated glycerides decreased. The linolenic glycerides of lumbang oil were oxidised more readily than the linolic and the linolic more readily than the oleic glycerides. H. C. R.

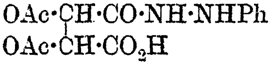
Quantitative Reduction by Hydriodic Acid of Halogenated Malonyl Derivatives. III. Mechanism of the Reaction. R. W. West (*J. Chem. Soc.*, 1924, **125**, 710—721).—The reaction between α-bromomalonyldimethylamide and hydriodic acid is bimolecular, and is probably indicated by the scheme $\cdot CO\cdot CHBr\cdot \longrightarrow \cdot C(OH){:}Br\cdot \longrightarrow \cdot CI(OH)\cdot CHBr\cdot \longrightarrow \cdot C(OH){:}CH + IBr$ (cf. Meyer, A., 1911, i, 350). The rate of reaction between hydriodic acid and αα′-dibromo-, αα′-chlorobromo-, and α-bromo-α′-alkylmalondimethylamides is independent of the concentration of the potassium iodide, but varies with that of the acid present, indicating that the primary (slow) reaction is the hydrolysis $:CXBr + H_2O = :CXH + HOBr$, which is followed by the instantaneous reduction of the hypobromous acid. The rate of reduction of the α-bromo-α′-alkylmalondimethylamides decreases in the order *iso*butyl (methyl), *n*-propyl, *iso*propyl, *n*-butyl, ethyl, which is identical with that for the rates of formation of the methylamides from the corresponding ethyl α-alkylmalonates. The effect is to be ascribed to steric hindrance rather than to polarity. The following α-alkylmalondimethylamides are obtained by heating the corresponding α-alkylmalonic ethyl esters with alcoholic monomethylamine at 100—140°: α-*methyl-*, colourless plates, m. p. 154°; α-*ethyl-*, small needles, m. p. 176°; α-n-*propyl-*, thin needles, m. p. 171°; α-iso*propyl-*, colourless needles, m. p. 167°; α-n-*butyl-*, colourless needles, m. p. 177°, and α-iso*butyl-malonodimethylamide*, thin needles, m. p. 163°. α-*Bromo-*α′-*methylmalonodimethylamide*, colourless needles, m. p. 114°, was prepared by brominating the above methyl derivative in chloroform, the following by brominating the corresponding α-alkylmalonodimethylamides in glacial acetic acid, all as colourless needles: α-*bromo-*α′-*ethyl-*, m. p. 136°; α-*bromo-*α′-n-*propyl-*, m. p. 106°; α-*bromo-*α′-iso*propyl-*, m. p. 101°; α-*bromo-*α′-n-*butyl-*, m. p. 89°, and α-*bromo-*α′-iso*butyl-malonodimethylamide*, m. p. 111°. F. G. W.

Action of Diacetyltartaric Anhydride and Chlorofumaryl Chloride on Aromatic Amines and Hydrazines. F. D. Chattaway and G. D. Parkes (*J. Chem. Soc.*, 1924, **125**, 464—470).—Phenyliminosuccinanil (cf. T., 1923, **123**, 663) is obtained by the action of aniline on chlorofumaranilide at 150°. *Chloromaleinanil*,  $\left.\begin{matrix} CCl\cdot CO \\ \| \\ CH\cdot CO \end{matrix}\right> NPh$, small, colourless needles, m. p. 170°, is formed on heating the aniline salt of chloromaleic or chlorofumaric acid at 170—180°, and yields phenyliminosuccinanil on heating with aniline. *Chloromalein-*p-*chloroanil*, minute, glistening, irregular plates, m. p. 175°, and *chloromalein-*p-*bromoanil*, microcrystalline powder, m. p. 190°, are obtained similarly. *Chlorofumarodiamide*,

$CONH_2\cdot CCl\colon CH\cdot CONH_2$, needles, m. p. 187°, *chlorofumaro-dimethylamide*, minute, colourless needles, m. p. 173°; *-di-p-chloroanilide*, clusters of pale yellow needles, m. p. 223°; and *-di-p-bromoanilide*, minute, faintly yellow needles, m. p. 236°, are obtained by the action of chlorofumaryl chloride on ammonia and the corresponding amines, respectively. The di-*p*-bromoanilide is also obtained by the action of bromine in glacial acetic acid on chlorofumarodianilide.

Aqueous potassium hydroxide hydrolyses phenyliminosuccinanil with formation of β-anilinoacrylic acid, whilst in alcohol the products are aniline, potassium oxalate, and potassium acetate.

Phenylhydrazine diacetyltartrate, a white, microcrystalline powder, melts partly at about 70° with loss of water and formation of *diacetyltartarophenylhydrazido-acid* (I), m. p. 168°, with formation of *α-diacetyltartarophenylhydrazide* (II), small, faintly yellow needles,



$$\begin{array}{l} OAc\cdot CH\cdot CO\cdot NH\cdot NHPh \\ OAc\cdot CH\cdot CO_2H \end{array}$$

(I.)

$$\left.\begin{array}{l} OAc\cdot CH\cdot CO \\ OAc\cdot CH\cdot CO \end{array}\right> N\cdot NHPh$$

(II.)

$$\begin{array}{l} OAc\cdot CH\cdot CO\cdot NPh \\ OAc\cdot CH\cdot CO\cdot NH \end{array}$$

(III.)

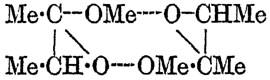
m. p. 156°, and this, on warming with sodium ethoxide in alcohol, is converted into β-*diacetyltartarophenylhydrazide* (III), minute, colourless, irregular plates, m. p. 256°. The action of excess of phenylhydrazine on diacetyltartaric anhydride, or on the above α-hydrazide, affords tartarodiphenylhydrazide (T., 1903, **83**, 1349) and acetylphenylhydrazine. F. G. W.

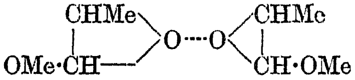
Formals of Primary Alcohols. M. GHYSELS (*Bull. Soc. chim. Belg.*, 1924, **33**, 57—78).—Formals have been prepared by a direct distillation method from methyl, ethyl, *n*-propyl, *n*-butyl, *iso*butyl, and *n*-amyl alcohols. A non-volatile catalyst such as sulphuric acid or toluene-*p*-sulphonic acid is used which is eliminated immediately by the distillation. High yields of practically pure formals can be obtained in a single operation except in the cases of methylformal and ethylformal. Methylformal forms with the excess of alcohol an azeotropic mixture containing 92·15% of formal. Ethylformal gives a ternary azeotropic mixture with the excess of alcohol and the water produced in the reaction, from which it is separated by the addition of carbon disulphide; after separation of the aqueous layer and removal of the carbon disulphide, the ethylformal is obtained practically pure. *n*-Propylformal also yields a ternary azeotropic mixture with the excess of alcohol and water. All the formals prepared give binary azeotropic mixtures with water. The boiling points and approximate composition of these mixtures are given. R. B.

Glucosidic Acetals derived from Simple α- or β-Hydroxyketones and their Polymerisation. M. BERGMANN and S. LUDEWIG (*Annalen*, 1924, **436**, 173—183; cf. Bergmann and Miekeley, A., 1921, i, 763; Fischer, A., 1895, i, 437).—The formation of glucosidic compounds from α- or β-hydroxy-aldehydes or -ketones has not previously been observed. The authors have shown that simple α-hydroxyketones, such as acetol, acetoin, and benzoylcarbinol, yield glucosidic *cyclo*acetals on treatment with methyl alcohol and hydrogen chloride, according to the scheme

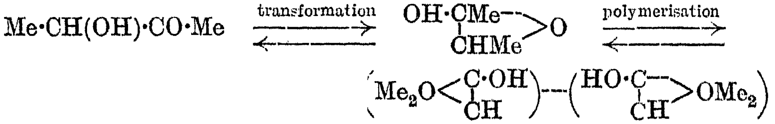
$$R\cdot CO\cdot CHR'(OH) \longrightarrow \begin{matrix} CHR' \\ O\text{———} \end{matrix}\!\!>CR\cdot OMe.$$

These *cyclo*acetals polymerise easily, being bimolecular in solution and in the vapour phases at low pressures and temperatures; when strongly heated, they dissociate, but on cooling the bimolecular form is again obtained as crystals. This phenomenon is a property of an αβ-oxygen bridge in glucosides, but the three cases mentioned are peculiar, as in the gaseous state they are easily dissociated. The acetals of acetoin and glycollaldehyde are bimolecular over a comparatively wide range of temperature, whereas acetol*cyclo*acetal is dissociated at 100° under a pressure of a few millimetres. The derivatives of benzoylcarbinol cannot be examined owing to their high melting points. The following formulæ are suggested for dimeric acetoin*cyclo*acetal.





It is known that α-hydroxy-aldehydes and -ketones themselves polymerise to bimolecular forms, acetoin being an example. Refractometric measurements indicate that the unimolecular liquid form of acetoin possesses an alicyclic hydroxy-carbonyl structure. The change to the bimolecular crystalline form and the slow reverse change (at the ordinary temperature) indicate some structural alteration for which the following scheme is suggested:



Acetoin, b. p. 140—144°, d_4^{17} 0·9972, $n_D^{17\cdot3}$ 1·4190, is best prepared from γ-bromobutan-β-one by warming with an excess of potassium formate in dry methyl alcohol or with water and freshly precipitated calcium carbonate or potassium hydrogen carbonate. It is converted by acetic anhydride and pyridine into the acetate, b. p. 169—173°, $d_4^{16\cdot5}$ 1·038, $n_D^{16\cdot5}$ 1·4157.

Acetoin may be polymerised by the action of granulated zinc at —15° (cf. Diels and Stephan, A., 1907, i, 1000), when colourless crystals slowly separate, m. p. 83° (cf. von Pechmann and Dahl, A., 1890, 1234). Vapour density determinations in all cases were made by the method of Bleyer and Kohn, whence M=91 (req.=88) at 140°/2 mm. *Methyl*cyclo*acetal* was prepared from acetoin by the action of 1% methyl-alcoholic hydrogen chloride at 0°; bisacetoin may be employed (m. p. 73—73·5°, b. p. 196—198°/745 mm.). In phenol solution, it is bimolecular and also at 80°/0·8 mm., but at higher temperatures the vapour dissociates and is unimolecular at 140°/2 mm.

Acetol methyl*cyclo*acetal (m. p. 127°), prepared from acetol by means of methyl-alcoholic hydrogen chloride, at 100°/10 mm. is partly bimolecular, but at 140°/1·5 mm. it is unimolecular.

Ethylglycoloside (cf. Bergmann and Miekeley, *loc. cit.*) is bimolecular at 140°/8 mm., and unimolecular at 180°/10 mm.

The methyl*cyclo*acetal of benzoylcarbinol, m. p. 192°, was unimolecular at 200°, but at higher temperatures some secondary changes took place which interfered with the accuracy of the measurements. A. E. C.

Isomerism of Thioaldehydes. E. FROMM and M. SOFFNER (*Ber.*, 1924, **57**, [*B*], 371—373).—A reply to Hinsberg (A., 1923, i, 1056; cf. Fromm and Schultis, A., 1923, i, 580).—The crude product (m. p. 216°) of the action of hydrogen sulphide on formaldehyde, whether freshly prepared or preserved during several months, loses hydrogen sulphide when treated with lead oxide and sodium hydroxide. It is converted into the substance, m. p. 247° (Hinsberg's β-trithioformaldehyde), not only by hydriodic acid, but also by concentrated hydrochloric acid; the change is therefore due to transformation and not to reduction. The sulphoxides derived from trithioformaldehyde, m. p. 216°, and from the substance, m. p. 247°, are probably identical; their solubilities are the same, and they yield the same product when treated with concentrated hydriodic acid.

The properties of the compound formed from hydrogen sulphide and formaldehyde appear to be in harmony with the formula $SH\cdot CH_2\cdot S\cdot CH_2\cdot S \ldots\ldots CH_2\cdot S\cdot CH_2\cdot SH$; the length of the chain cannot be determined, since there is no available method for the examination of the molecular weight of the compound. Oxidation of trithioformaldehyde or of the polymeric thioaldehyde, m. p. 247°, by hydrogen peroxide in acetic acid solution does not afford much insight into their constitution, since it is very probable that either compound is resolved into monomeric thioformaldehyde in the initial stages of the change.

α-Trithioformaldehyde, m. p. 216°, is the only compound of the group to which a definite molecular weight can be assigned. The degree of polymerisation of the product, m. p. 247°, cannot be ascertained, and it is purely arbitrary to regard it as a trimeride. H. W.

Formation of Acetone from Acetates. E. HÄGGLUND and E. O. HEDMAN (*J. pr. Chem.*, 1924, [ii], **107**, 50—64).—Dry distillation of sodium acetate at 400° in a current of steam gives nearly as high a yield of acetone as the distillation of calcium acetate; when inert gases such as nitrogen are used in place of steam, the yield of acetone is not raised in this way. Mixing the sodium acetate with calcium oxide or carbonate or sodium carbonate raises the yield of acetone considerably, and also accelerates the reaction, acetone formation being practically complete in the first hour instead of in 3—4 hours. This accelerating action was also observed in an atmosphere of nitrogen. Rather more carbon monoxide and less carbon dioxide were produced than in the distillation of calcium acetate. Methane was only produced in quantity when sodium hydroxide was added to the sodium acetate; in this case very little acetone was produced. R. B.

Density and Viscosity of Acetone at Low Temperatures. E. H. Archibald and W. Ure (*J. Chem. Soc.*, 1924, **125**, 726—731).—The following values were obtained for the density of acetone at the temperatures given: 0·0°, 0·8140; —10·0°, 0·8251; —20·0°, 0·8370; —30·0°, 0·8473; —40·0°, 0·8575; —50·0°, 0·8777; —70·0°, 0·8884; —80·0°, 0·9002; and —90·0°, 0·9117. Corresponding viscosities (absolute units) are: 0°, 0·00389; —10·6°, 0·00451; —20·4°, 0·00517; —30·3°, 0·00613; —40·0°, 0·00713; —49·9°, 0·00818; —59·7°, 0·00981; —69·7°, 0·01200; —79·7°, 0·01505; and —89·7°, 0·02051. The large increase in viscosity–temperature coefficient may account for the large conductivity–temperature coefficients found for solutions of organic substances in the liquid halogen hydrides. F. G. W.

Interaction of Tellurium Tetrachloride and the Higher β-Diketones. I. G. T. Morgan and H. D. K. Drew (*J. Chem. Soc.*, 1924, **125**, 731—754).—The course of the reaction between tellurium tetrachloride and β-diketones, in chloroform or benzene, is determined by the complexity of the carbon chain of the diketone. If the solvent contains alcohol, the latter may enter into the reaction. The tellurium β-diketones, obtained by reducing the tellurium β-diketone dichlorides with potassium metabisulphite, are powerful bactericides (*Biochem. J.*, 1924, **18**, 190).

[With C. R. Porter.]—*n*-Butyrylacetone yields, in pure chloroform, *tellurium* n-*butyrylacetone dichloride* (I), transparent, colourless prisms, m. p. 153—154° after darkening at 144°; in presence of alcohol, *tellurium* O-*ethyl*-n-*butyrylacetone trichloride* (III), golden-yellow needles, m. p. 105·5—106·5° (decomp.), is also formed.

(I.)

$R\cdot C\colon CH\cdot CO\cdot CH_2\cdot TeCl_2$ (ring closed through O)

$R\cdot C\colon CH\cdot CO\cdot CH_2\cdot Te$ (ring closed through O)

(II.)

$C_3H_7\cdot C(OEt)\colon CH\cdot CO\cdot CH_2\cdot TeCl_3$ (III.)

$C_6H_{13}\cdot CO\cdot CH\colon C(OH)\cdot CH_2\cdot TeCl_3$ (IV.)

Tellurium n-*butyrylacetone*, $C_7H_{10}O_2Te$ (II), forms yellow needles, m. p. 110—112°. *n*-Heptoylacetone yields *tellurium* n-*heptoylacetone dichloride* (see I), nacreous, compact, or acicular prisms, m. p. 87°, and *tellurium* n-*heptoylacetone trichloride* (IV), colourless, nacreous, six-sided plates, m. p. 117° (decomp.). *Tellurium* n-*heptoylacetone*, $C_{10}H_{16}O_2Te$ (see II), forms yellow needles or golden-yellow scales, m. p. 86°, and shows residual acidity. The trichloride is not converted into the cyclic dichloride on boiling with pure chloroform, and addition of anhydrous aluminium chloride led to the formation of a crystalline aluminium derivative.

[With I. Ackerman.]—Dipropionylmethane yields *tellurium dipropionylmethane dichloride*, $C_7H_{10}O_2Cl_2Te$, thin, colourless, six-sided plates (from acetone or benzene) darkening at 157°, and intumescing at 162°, or glistening prisms (from methyl alcohol), darkening at 150° and intumescing at 170° (cf. T., 1921, **119**, 616), and *tellurium* O-*ethylpropionylmethane trichloride*, $C_9H_{15}O_2Cl_3Te$, transparent, lemon-yellow prisms, m. p. 110—111° (decomp.). *Tellurium dipropionylmethane*, $C_7H_{10}O_2Te$, forms very tough, golden-yellow needles, m. p. 151° (decomp.), sublimes at 110° under reduced pressure, and shows no enolic reactions.

Tellurium propionyl-n-*butyrylmethane dichloride*, $C_8H_{12}O_2Cl_2Te$, forms silvery flakes, darkening at 150°, m. p. 156° (decomp.). *Tellurium propionyl*-n-*butyrylmethane*, $C_8H_{12}O_2Te$, forms yellow needles, m. p. 101—102° (decomp.). *iso*Butyrylacetone (b. p. 163°/752·5 mm.; *copper* salt, light blue, voluminous, crystalline powder, m. p. 167—168°) yields *tellurium* O-*ethyl*iso*butyrylacetone trichloride*, $C_9H_{15}O_2Cl_3Te$, pale yellow flakes or needles, m. p. 103° (decomp.). *iso*Valerylacetone (b. p. 183°/741 mm.; copper salt, m. p. 154°) yields *tellurium bis*iso*valerylacetone dichloride*,

$$C_{16}H_{26}O_4Cl_2Te,$$

transparent, colourless, acicular prisms, or nacreous leaflets, m. p. 97—98° (decomp.), and *tellurium* O-*ethyl*iso*valerylacetone trichloride*, small, compact, lemon-yellow, gem-like crystals, changing at 88° to a yellow glass having m. p. 101—102° (decomp.). *γ-Methylpropionylacetone* [*copper* salt, dark olive-green crystals, m. p. 174—176° (decomp.), or greenish-grey needles, m. p. 175—177° (decomp.)], yields *tellurium γ-methylpropionylacetone dichloride*, colourless, glistening prisms, m. p. 166—167° (decomp.) after sintering at 164°, which is reduced to the neutral *tellurium γ-methylpropionylacetone*, long, soft, pale golden needles, or elongated prisms, m. p. 125—126° (decomp.), subliming at 100° in a vacuum. *γ-Ethyl*-n-*butyrylacetone*, colourless, fragrant oil, b. p. 101—102°/9 mm. [*copper* salt, m. p. 166° (decomp.)], yields *tellurium γ-ethyl*-n-*butyrylacetone dichloride*, nacreous rosettes of colourless, prismatic needles, m. p. 140° (decomp.). *Tellurium γ-ethyl*-n-*butyrylacetone*,

$$C_9H_{14}O_2Te,$$

forms yellow needles, sintering at 110°, m. p. 113°, and is non-enolic.

Dipropionylethylmethane, $Et\cdot CH(CO\cdot Et)_2$, forms a colourless oil with a pleasant, slightly peppery odour, b. p. 105—106°/13 mm., 202—203°/744 mm. [*copper* salt, grey, microcrystals (from alcohol), m. p. 178—180°, or silver-grey needles (from benzene), m. p. 174—176°]. *Tellurium dipropionylethylmethane dichloride* forms colourless, transparent, six-sided prisms, darkening from 172°, m. p. 182° (decomp.), and is reduced to *tellurium dipropionylethylmethane*, tough, golden needles, m. p. 137—138° (decomp.), subliming at 110° in a vacuum. *Tellurium γγ-diethylacetylacetone dichloride* forms colourless, nacreous flakes or prisms, softening at 177°, m. p. 178—180°. *Tellurium γγ-diethylacetylacetone* forms brittle, yellow, acicular needles, or needles with characteristically serrated edges, m. p. 85—86°, and has no residual acidity.

Diacetylacetone yields a mixture of *dimethylpyrone tellurichloride* (V), spear-like aggregates of golden-yellow needles, and the *oxy-*

chloride $[(C_7H_8O_2)H]_2TeOCl_4$, colourless crystals, m. p. 115°. Tetraacetylethane yields a *substance* crystallising in pale golden, six-sided plates or needles, blackening at 135°, which is hydrolysed

(V.)

$$\left[\mathrm{O}{<}\begin{smallmatrix}\mathrm{CMe{:}CH}\\ \mathrm{CMe{:}CH}\end{smallmatrix}{>}\mathrm{C{:}O}\ .\ .\ .\ \mathrm{H}\right]_2{<}\mathrm{TeCl_6};$$

$$\left[\mathrm{CH_2}{<}\begin{smallmatrix}\mathrm{CMe_2{-}CH_2}\\ \mathrm{C(OH){:}CH}\end{smallmatrix}{>}\mathrm{C{:}O}\ .\ .\ .\ \mathrm{H}\right]_2{<}\mathrm{TeCl_6};$$

(VI.)

with formation of 3 : 4-diacetyl-2 : 5-dimethylfuran, of which it is probably the tellurichloride. Dimethyldihydroresorcinol affords *dimethyldihydroresorcinol tellurichloride* (VI), large, transparent, pale yellow prisms, resinifying at 130°, m. p. 160—165° (decomp.). Ethyl acetoacetate yields *tellurium ethyl* O-*ethylacetoacetate trichloride* (*tellurium ethyl* β-*ethoxycrotonate trichloride*),

$$\mathrm{CO_2Et{\cdot}CH{:}C(OEt){\cdot}CH_2{\cdot}TeCl_3},$$

colourless plates, softening at 88°, m. p. 90—92° (decomp. 140°). Definite products were not obtained by condensing tellurium tetrachloride with ethyl malonate, 3-allylacetylacetone, acetylmesityl oxide, acetylcamphor, ω-phenylacetylacetone, benzylidenebisacetylacetone (non-enolic and dienolic forms) and 2-acetyl*cyclo*hexanone). The benzeneazo-β-diketones yield bright yellow, stable compounds containing tellurium and halogen. F. G. W.

Interaction of Tellurium Tetrachloride and the Higher β-Diketones. II. G. T. MORGAN and R. W. THOMASON (*J. Chem. Soc.*, 1924, **125**, 754—759).—*Dibutyrylmethane*,

$$\mathrm{CH_2(CO{\cdot}C_3H_7)_2},$$

is obtained as a fragrant, colourless liquid, b. p. 204—205°, by the condensation of methyl propyl ketone with *n*-butyl *n*-butyrate or (in better yield) with ethyl *n*-butyrate. It forms a blue *copper* salt, m. p. 156°, and condenses with *p*-nitrophenylhydrazine to form 1-p-*nitrophenyl*-3 : 5-*di*-n-*propylpyrazole*, $C_{15}H_{19}O_2N_3$, yellowish-brown needles, m. p. 53°. It condenses with tellurium tetrachloride in chloroform with formation of *tellurium dibutyrylmethane dichloride* (I), vitreous needles (from methyl alcohol), m. p. 148°, or colourless needles (from alcohol or chloroform–petroleum), m. p. 120—139° or 138—139°, and *tellurium dibutyrylmethane trichloride*, $\mathrm{Pr^{\alpha}CO{\cdot}CH{:}C(OH){\cdot}CHEt{\cdot}TeCl_3}$ or $\mathrm{Pr^{\alpha}C(OH){:}CH{\cdot}CO{\cdot}CHEt{\cdot}TeCl_3}$, large, tabular crystals, m. p. 87—88°, with blackening. Both forms of the dichloride are reduced, with alkali hydrogen sulphite, to *tellurium dibutyrylmethane* (II), golden-yellow needles, m. p. 97°.

(I.)

$$\mathrm{Pr^{\alpha}\overbrace{C{:}CH{\cdot}CO{\cdot}CHEt{\cdot}Te}^{O}Cl_2}$$

$$\mathrm{Pr^{\alpha}\overbrace{C{:}CH{\cdot}CO{\cdot}CHEt{\cdot}Te}^{O}}$$

(II.)

γ-*Ethylpropionylacetone*, $C_2H_5{\cdot}CO{\cdot}CHEt{\cdot}CO{\cdot}CH_3$, obtained by the action of ethyl iodide on sodium propionylacetone, forms a fragrant oil, b. p. 192—193°/755 mm. (*copper* salt, m. p. 176°). *Tellurium* γ-*ethylpropionylacetone dichloride*, $C_8H_{12}O_2Cl_2Te$, acicular prisms, m. p. 167° (decomp.), and *tellurium* γ-*ethylpropionylacetone*, $C_8H_{12}O_2Te$, pale yellow needles, m. p. 109°, are described.

γ-n-*Propylacetylacetone* was obtained as a fragrant oil, b. p.

191—192°/745 mm. (*copper* salt, m. p. 215°), by the action of *n*-propyl iodide on sodium acetylacetone at 180° under pressure (cf. T., 1920, **117**, 780). *Tellurium* γ-n-*propylacetylacetone dichloride*, $C_8H_{12}O_2Cl_2Te$, forms colourless, acicular prisms, m. p. (indefinite) 180°. *Tellurium* γ-n-*propylacetylacetone*, $C_8H_{12}O_2Te$, forms pale yellow needles, m. p. 106—107°. γ-iso*Propylacetylacetone*, prepared similarly to the *n*-propyl derivative, b. p. 182—183°/745 mm., has an odour of dry hay. It does not form a copper salt, and gives no coloration with ferric chloride. *Tellurium* γ-iso*propylacetylacetone dichloride* forms lustrous, colourless, acicular prisms, blackening indefinitely at about 150°. *Tellurium* γ-iso*propylacetylacetone* forms yellow needles, m. p. 152—153°. F. G. W.

Interaction of Tellurium Tetrachloride and the Higher β-Diketones. III. G. T. Morgan and E. Holmes (*J. Chem. Soc.*, 1924, **125**, 760—765).—The isolation of the condensation products of tellurium tetrachloride and the β-diketones is rendered more difficult, as the series is ascended, by their increasing fusibility and solubility in organic media. n-*Valerylacetone*, a pungent oil, b. p. 194° (blue *copper* salt, m. p. 143°), is converted by tellurium tetrachloride into *tellurium* n-*valerylacetone dichloride*, $C_8H_{12}O_2Cl_2Te$ ($R=n\text{-}C_4H_9$, $R'=H$, in formula I), colourless needles, m. p. 125°; this is reduced by potassium metabisulphite to *tellurium* n-*valerylacetone*, $C_8H_{12}O_2Te$ (see II), yellow needles, m. p. 80°. *n*-Hexoylacetone (blue *copper* salt, m. p. 138°) gives *tellurium* n-*hexoylacetone dichloride* ($R=n\text{-}C_5H_{11}$, $R'=H$, in I), colourless needles, m. p. 102°. *Tellurium* n-*hexoylacetone* (see II) forms brilliant yellow needles, m. p. 86°.

$\overbrace{R\cdot C{:}CR'\cdot CO\cdot CH_2\cdot Te}^{O}Cl_2$;

(I.)

$\overbrace{R\cdot C{:}CR'\cdot CO\cdot CH_2\cdot Te}^{O}$;

(II.)

γ-n-*Butylacetylacetone*, b. p. 210—212°/750 mm. (grey *copper* salt, m. p. 186°) was prepared by the action of *n*-butyl iodide on sodium acetylacetone. *Tellurium* γ-n-*butylacetylacetone dichloride* ($R=CH_3$, $R'=n\text{-}C_4H_9$, in I), lustrous, colourless crystals, m. p. 155°, is reduced to *tellurium* γ-n-*butylacetylacetone* (see II), primrose-yellow needles, m. p. 129°. γ-n-*Butylpropionylacetylacetone*, similarly obtained from propionylacetone, has b. p. 223—224°/745 mm. (*copper* salt, grey needles, m. p. 156°). *Tellurium* γ-n-*butylpropionylacetone dichloride* ($R=C_2H_5$, $R'=n\text{-}C_4H_9$, in I), forms colourless leaflets, m. p. 103°. *Tellurium* γ-n-*butylpropionylacetone* (see II) forms golden-yellow needles, m. p. 93°. Methyl *n*-nonyl ketone was condensed with ethyl acetate and sodium to form n-*decoylacetone*, an oil with a sweet, penetrating odour, b. p. 276°/760 mm. (*copper* salt, pale blue needles, m. p. 114°). *Tellurium* n-*decoylacetone dichloride* ($R=n\text{-}C_9H_{19}$, $R'=H$, in I), forms grey crystals, m. p. 49°, and *tellurium* n-*decoylacetone* (see II), yellow needles, m. p. 64°. F. G. W.

Bactericidal Action of the Tellurium Derivatives of Aliphatic β-Diketones. II. G. T. Morgan, E. A. Cooper, and A. W. Burtt.—(See i, 591.)

Pentosans. VII. Fusion of Xylan with Potassium Hydroxide. E. HEUSER and J. ROTH (*J. pr. Chem.*, 1924, [ii], **107**, 1—6; cf. A., 1923, i, 1061, 1181).—Fusion of xylan with 10 parts of potassium hydroxide and an equal weight of water for ½ hour to 2 hours gives oxalic, acetic, and formic acids in amounts depending on the temperature. Oxalic acid is formed most readily at 220—250° (yield 53%), with some evolution of hydrogen. Below 200° much xylan remains unchanged. The yields of acetic acid and formic acid at 230—280° vary from 13—15% and 9—12%, respectively. The presence of succinic acid has been proved, but its amount could not be determined. Succinic acid is not formed in the fusion and subsequently decomposed, for this acid was recovered practically unchanged after fusion with potassium hydroxide. Traces of pyrocatechol and protocatechuic acid have been detected, but the presence of these and other aromatic substances is attributed to the presence of impurities in the xylan. The amount of formic acid produced leads to the conclusion that the oxalic acid results from decomposition of the formate, as in the fusion of cellulose, a conclusion which was confirmed by measuring the hydrogen evolved when the fusion was conducted in a stream of nitrogen. R. B.

Mutarotation of the Sugars. R. GILMOUR (*J. Chem. Soc.*, 1924, **125**, 705—706).—A question of priority (cf. Gilmour, P., 1909, **25**, 225; Baker, Ingold, and Thorpe, this vol., i, 262). F. G. W.

Chemical Effects of γ-Rays of Radium. A. SLOSSE (*Compt. rend. Soc. Biol.*, 1923, **89**, 96—98; from *Chem. Zentr.*, 1924, i, 33—34).—The effect of the radiations from radium bromide enclosed in a sealed tube and immersed in a solution of pure dextrose was to produce a small decrease in optical activity, attributed to a partial transformation of β- into γ-dextrose. The presence of formaldehyde was established; no other degradation products of dextrose were found. After subjection to radiation, the dextrose solution became much more readily oxidisable by potassium permanganate and sulphuric acid. G. W. R.

Glucose [Dextrose] from α- and β-Glucosides. H. COLIN and [MLLE.] A. CHAUDUN (*Compt. rend.*, 1924, **178**, 779—782).—The hydrolysis of α- and β-methyl-, of α- and β-ethyl-glucosides, and of salicin, has been followed polarimetrically and by copper titration. Salicin hydrolyses initially to give a glucose of low rotatory power (increasing with time) and is therefore a β-glucoside. E. E. T.

Acetone-sugars and their Derivatives. I. The Constitution of Glucosediacetone [Di*iso*propylidene-glucose] and a new Benzoylglucosemonoacetone. H. OHLE (*Ber.*, 1924, **57**, [*B*], 403—409).—The action of aniline hydrochloride on benzoylglucosediacetone (Fischer and Noth, A., 1918, i, 226) in boiling, absolute alcoholic solution leads to the formation of a second *benzoylglucosemonoacetone*, $CMe_2{:}C_6H_9O_5{\cdot}OBz$, $[\alpha]_D^{20}$ −26° in alcoholic solution, which could not be caused to crystallise. In so far as hydrolysis does not occur, it is stable towards dilute acids, but is rapidly converted by traces of alkali into the crystalline benzoylglucosemonoacetone of Fischer and Noth (*loc. cit.*). The constitution of the new derivative has not been established completely, but it is considered to be the primary product of the action from which Fischer's compound is obtained by isomerisation. Since Fischer, Pfähler, and Brauns (A., 1920, i, 840) have shown that the wandering of acyl groups occurs from the secondary to the primary alcoholic hydroxy group, it is assumed that the crystalline product is ζ-benzoylglucosemonoacetone. This hypothesis is supported by the observations that it is the sole isolable product of the action of benzoyl chloride on glucosemonoacetone in the presence of pyridine, and that both benzoylglucosemonoacetones are convertible into the same tribenzoylglucosemonoacetone, the experimental conditions being such that isomerisation is excluded.

Glucosemonoacetone reacts with acetone to form glucosediacetone as readily in the presence of anhydrous copper sulphate as in that of hydrogen chloride. A similarly ready reaction is observed in the cases of glycerol and of glyceryl α-benzoate.

It is suggested that the wandering of acyl and alkyl groups is more frequent than has been assumed previously in the chemistry of the sugars. The discordant results obtained by Irvine and Patterson (T., 1922, **121**, 2146) and by Levene and Meyer (A., 1923, i, 92) by the oxidation of methylglucosediacetone are probably attributable to this cause. H. W.

Crystallisation of Sucrose. J. A. KUCHARENKO (*Louisiana Planter*, 1923, **71**, 211—213, 231—232).—The concentration of supersaturated solutions of sucrose at the instant of crystallisation was determined at various temperatures; by the correlation of surface, S, and weight, P, in the equation $S^3 = kP^2$, the rate of crystallisation of solutions of various degrees of supersaturation could be accurately measured. The speed of crystallisation was found to vary directly with the degree of supersaturation and with the temperature employed. CHEMICAL ABSTRACTS.

The System Maltose–Water. J. GILLIS (*Rec. trav. chim.*, 1924, **43**, 135—143).—The author has studied the lowering of the melting point of ice for high concentrations of maltose both in pure water and in the presence of ammonia. The resulting curve is shown together with the solubility curve of maltose between 0° and 96·5°. From the latter, the inference is drawn that the monohydrate of β-maltose exists as the solid phase in equilibrium with the solution up to the neighbourhood of 100°. The solubility curve is compared with the curves of lactose (Gillis, A., 1921, i, 11) and of dextrose (Jackson and Silsbee, A., 1922, i, 986). H. J. E.

Acetobromomaltose. H. FISCHER and F. KÖGL (*Annalen*, 1924, **436**, 219—228; cf. E. and H. Fischer, A., 1910, i, 716; Karrer, A., 1921, i, 310, 313, 768).—The authors question the purity of the acetobromomaltose obtained by Karrer's method, as from this specimen a yield of only 30% of hepta-acetylmaltose is obtainable, whereas from their specimen a 70% yield is produced. Further, the acetobromomaltose obtained by Karrer's method has a very high bromine content, which indicates that some secondary reaction has taken place. Pure acetobromomaltose is prepared by allowing maltose to stand with acetyl bromide for 20—40 minutes at 0°; it is an amorphous solid which after 7 months' drying gave $[\alpha]_D^{15\cdot5}$ +171·5° in chloroform. Hepta-acetylmaltose, microscopic needles, m. p. 174—175°, was obtained by the action of sodium acetate and acetic acid on the bromo compound, the total yield being 70%. The specific rotation increased to a constant value on preservation, and, after 48 hours, is $[\alpha]_D^{10}$ +103·01° in *s*-tetrachloroethane.

Hepta-acetylbenzylmaltoside, colourless prisms, m. p. 125°, $[\alpha]_D^{16\cdot5}$ +27·76° in *s*-tetrachloroethane, was prepared from an absolute ethereal solution of the bromo compound by shaking with silver carbonate and benzyl alcohol. It is hydrolysed by methyl-alcoholic ammonia at 0° to *benzylmaltoside*, m. p. 147—148°, $[\alpha]_D^{17}$ +47·64° in aqueous solution.

Hepta-acetylethylmaltoside, prepared in the same way as the benzyl derivative, crystallises in prisms, m. p. 132°, $[\alpha]_D^{14}$ +48·93° in *s*-tetrachloroethane. It is hydrolysed to *ethylmaltoside*, m. p. 168—169°.

Hepta-acetylmethylmaltoside, m. p. 130—131°, is prepared in the same manner as the ethyl homologue. *Hexa-acetylmaltal* is obtained by the reduction of a solution of the acetobromomaltose in 50% acetic acid by zinc dust at 10°; it crystallises in colourless prisms, m. p. 134°, $[\alpha]_D^{16\cdot5}$ +64·15°. It adds on one atomic proportion of bromine in chloroform solution and on warming with water loses one acetyl group, leaving the penta-acetyl derivative as fine needles, m. p. 123°. This on acetylation with acetic anhydride and pyridine gives a substance, m. p. 113—114°, which has not been further examined.

A. E. C.

Lactosan. A. Pictet and M. M. Egan (*Helv. Chim. Acta*, 1924, 7, 295—297).—When lactose is carefully heated at 120—130° at 4—6 mm., it loses its water of crystallisation, and at 185° in 10 to 12 hours it is converted into the anhydride, *lactosan*, $C_{12}H_{20}O_{10}$, a white, amorphous powder, m. p. 200—202° (decomp.), $[\alpha]_D$ +65·5—66·0°, without mutarotation. It is readily soluble in water, and its reducing power in terms of Fehling's solution is 61% of that of dextrose. Brewer's yeast does not ferment it. With phenylhydrazine, it gives the osazone of lactose, and when acetylated it gives octa-acetyl-lactose. Lactosan is polymerised by heating at 105°/15 mm. for $\frac{1}{4}$ hour with a trace of zinc chloride, forming a *tetralactosan*, $(C_{12}H_{20}O_{10})_4$, m. p. 245—246° (decomp.), which does not reduce Fehling's solution. By fuming hydrochloric acid, lactosan is partly converted into lactosyl chloride. The properties of lactosan indicate that it is ϵ-galactosylglucosan.

Degradation of Starch by Salts. W. S. Iljin (*Biochem. Z.*, 1924, **145**, 14—17; cf. also Iljin, A., 1923, i, 172; Haehn, A., 1923, i, 443; Biedermann, A., 1923, i, 665).—Further experiments are described in which starch in dilute solution is hydrolysed by various concentrations of sodium, lithium, and calcium chlorides without the intervention of an enzyme. Potassium, magnesium, and barium chlorides are said to give similar results. J. P.

Action of Weak Bases on Cellulose Nitrate. G. G. Giannini (*Gazzetta*, 1924, **54**, 79—85).—Determinations of the compositions and of the molecular weights in freezing acetic acid exhibited by two preparations of the product obtained by Angeli by the action of pyridine on cellulose nitrate (A., 1919, i, 196; 1922, i, 922) containing, respectively, 8·98% and 10·08% N, as well as analyses of the gaseous mixtures emitted during their preparation, suggest that pyridine produces in cellulose nitrate a gradual denitration varying in velocity with the temperature. T. H. P.

Triphenylmethyl Ethers of Cellulose and Starch. B. Helferich and H. Koester (*Ber.*, 1924, **57**, [*B*], 587—591; cf. A., 1923, i, 331).—Cellulose, preferably in the form of material which has been regenerated from the xanthate (1 part), is converted by triphenylmethyl chloride (6 parts) and pyridine (14 parts) at 100° during 14—32 hours into *cellulose triphenylmethyl ether*, $C_{25}H_{24}O_5$, a pale pink, voluminous powder, m. p. about 260° (decomp.), which swells in contact with many organic media and gives colloidal solutions in pyridine, chloroform, and bromoform. Further prolongation of the reaction or use of a larger excess of triphenylmethyl chloride does not lead to the etherification of more hydroxyl groups. The ether is readily hydrolysed by hydrogen chloride in chloroform solution, yielding triphenylmethyl chloride (or the carbinol if water is present) and a carbohydrate which is identical analytically with the original material. If triphenylmethylcellulose is heated with acetic anhydride and pyridine on the water-bath, approximately one acetyl group is introduced into each dextrose component; with chloroacetyl chloride and pyridine, esterification takes place to a greater extent. Rice starch yields *starch triphenylmethyl ether*, $C_{25}H_{24}O_5$, which closely resembles the corresponding cellulose ether. H. W.

Adsorption of Aluminium Hydroxide from Aluminium Sulphate Solutions by Cotton and Wood Cellulose. C. G. Schwalbe (*Z. angew. Chem.*, 1924, **37**, 125—128).—The contradictions which occur in the literature as to whether aluminium hydroxide is adsorbed from aluminium sulphate solutions by cotton and wood cellulose are ascribed to the fact that the adsorptive power of fibres is conditioned by a large number of variable factors such as the period and temperature of steeping, the concentration of the solution in which the fibre is steeped, and especially the previous history of the fibre, circumstances which have an important effect on the nature of its surface. Cotton cellulose which had been stored for 7 years in a dry place failed to adsorb aluminium from solutions of the sulphate or acetate or from sodium aluminate even after milling for 7 hours in a ball mill. In order to study the effects of the presence of hydrocellulose and oxycellulose, strips of cotton fabric were treated with 3% sulphuric acid and heated for 4 hours at 70°, and others were over-bleached before being used in adsorption experiments. The ash content of the samples so treated was found to increase very appreciably after steeping in an aluminium sulphate solution and subsequent washing. It is uncertain whether this increase in the adsorptive power of the fabric is due to the presence of hydrocellulose and oxycellulose or to a change in the nature and extent of the surface. Sized wood cellulose pulp is capable of adsorbing much greater quantities of aluminium hydroxide than the undamaged fibres, and the adsorptive power increases with the fineness of comminution up to a certain point, and thereafter remains approximately constant. The swelling of wood cellulose fibres exerts a great influence on their power of adsorbing aluminium hydroxide. The number of factors which affect the adsorptive power of wood cellulose is even greater than in the case of cotton cellulose, owing to the varying quantities of pentosans and hexosans which may be present. H. C. R.

Quantitative Determination of the Fluorescent Powers (the Spectro-fluorescometry) of Cellulose and its Derivatives. IV. S. J. Lewis (*J. Soc. Dyers and Col.*, 1924, **40**, 111—114).—A continuation of work previously described (this vol., i, 374). No essential differences were found in the fluorescent properties of yarn and ribbon prepared from the same solution of viscose, of hydrocellulose prepared by the action of sulphuric or hydrochloric acid on cotton linters, or of oxycellulose prepared by means of a hypochlorite or potassium permanganate. Experiments with cellulose tendered, by means of acids and exposure to daylight, indicate that changes in fluorescent power appear to be more noticeable in the region of λ 2900. Paper, after exposure for 3 weeks to radium, showed no fluorescence. It is again concluded that the physical condition of the material has but little effect on its fluorescent properties. A. J. H.

Polysaccharides. XXV. Methylation Products of Reserve Cellulose (Lichenin). P. Karrer and K. Nishida (*Helv. Chim. Acta*, 1924, 7, 363—370).—Continuing previous work (this vol., i, 373), fresh evidence is put forward confirming the chemical similarity between lichenin or reserve cellulose and structural cellulose. Exhaustive methylation of lichenin gives a product containing 41·9% of methoxyl, compared with a maximum of 42—43% in the case of cotton. Methylated lichenin dissolves in cold water to a colloidal solution which coagulates on warming. In some respects, it resembles methylated hydrocellulose more than methylated cellulose, but, unlike the former, it does not depress the freezing point of water. The methylated lichenin, when heated with 1% methyl-alcoholic hydrogen chloride, gives trimethyl- and dimethyl-methylglucosides in similar proportions to those obtained from fully methylated cellulose by Irvine and Hirst (T., 1923, **123**, 529). The yield of trimethylglucose obtained by hydrolysis of the glucoside is smaller, however, than the 85% obtained by Irvine and Hirst. E. H. R.

Galegine. E. Späth and S. Prokopp (*Ber.*, 1924, **57**, [*B*], 474—480; cf. Tanret, A., 1914, i, 859).—Galegine is converted by hydrogen in the presence of palladised charcoal to *dihydrogalegine*, $CHMe_2\cdot[CH_2]_2\cdot N{:}C(NH_2)_2$, the constitution of which is deduced from its conversion by barium hydroxide into carbamide and *iso*amylamine and its synthesis from *iso*amylamine and cyanamide. Since galegine on oxidation with permanganate yielded acetone but no trace either of formaldehyde or *iso*butaldehyde, it must have the composition $CMe_2{:}CH\cdot CH_2\cdot N{:}C(NH_2)_2$ (cf. Barger and White, this vol., i, 272). An improved method for the isolation of galegine is described, consisting essentially in extracting the free base from its aqueous solution by means of amyl alcohol. Dihydrogalegine sulphate, white crystals, the *picrate*, yellow crystals, m. p. 173—174°, and m-*nitrobenzoyl* derivative of *iso*amylamine, m. p. 81—82°, are described. F. A. M.

Composition of Japanese Petroleum. I. S. Komatsu and S. Kusumoto (*Mem. Coll. Sci. Kyōto*, 1924, **7**, 77—84).—The fraction of petroleum from Nishiyama, Echigo, distilling below 90°, is shown to consist mainly of methyl*cyclo*pentane, b. p. 71—72°, d_4^{25} 0·7295, n_D^{25} 1·3965, and *cyclo*hexane, b. p. 80—81°, d_4^{25} 0·765, n_D^{25} 1·414. [Cf. *B.*, 1924, 408.] W. A. S.

The Hydrogenating, Reducing, and Oxidising Action of Hydrazine on Organic Compounds. E. Müller and H. Kraemer-Willenberg (*Ber.*, 1924, **57**, [*B*], 575—583).—Benzyl alcohol reacts with 2 mols. of nearly anhydrous hydrazine at 180° to give nitrogen and toluene; if 4 mols. of hydrazine are used, hexahydrotoluene is obtained. At 280° benzene gives *cyclo*hexane, together with a small proportion of adipic acid (the requisite oxygen is derived from the trace of water present in the hydrazine). Toluene, *o*-, *m*-, and *p*-xylenes, mesitylene, and cymene are similarly transformed into their hexahydro-derivatives, hydrogenation occurring under milder experimental conditions with respect to temperature and duration as the number of carbon atoms in the hydrocarbon molecule increases. Pyridine and quinoline are not affected by hydrazine at any temperature up to 330°. Hydrobenzoin yields diphenylethylene oxide, m. p. 56°.

Monohydric phenols are not hydrogenated by hydrazine. At 100°, phenol gives the compound $(Ph\cdot OH)_2,N_2H_4$, m. p. 63°, which is unchanged by hydrazine at 200°. *p*-Cresol and *s*-xylenol yield similar *salts*, the *p*-cresol compound forming colourless needles, m. p. 61—62°. Polyhydric phenols are oxidised by hydrazine, as is evidenced by the copious formation of ammonia. *Quinol hydrazine*, $C_6H_{10}O_2N_2$, long, colourless needles, m. p. 154°, and resorcinol yield solid, nitrogenous products the constitution of which could not be elucidated.

Ethylene glycol is reduced by hydrazine at 200° to ethyl alcohol.

Glycerol is transformed into methyl alcohol, formic, acetic, and racemic acids. Erythritol yields oxalic acid, whereas dulcitol gives a hexose which is converted by phenylhydrazine into an osazone, $C_{18}H_{22}O_4N_4$, pale yellow needles, m. p. 205°. *d*-Mannitol yields dextrose. Cellulose is oxidised by hydrazine. H. W.

The System *cyclo*Hexane–Aniline. E. H. BUCHNER and D. KLEYN (*Rec. trav. chim.*, 1924, **43**, 153—157).—The critical temperatures of mixtures of *cyclo*hexane and aniline containing up to 40·1% of the latter were determined. The curve is regular and on extrapolation gives 427° as the critical temperature of aniline (cf. Guye and Malet, A., 1902, ii, 302). As no maximum was observed, the system is regarded as an exception to the general rule, and doubt is cast on the conclusions drawn by Buchner (A., 1918, ii, 9) in another case. The mutual solubilities of the two substances were also investigated; above 31·3°, there is complete miscibility in all proportions. H. J. E.

Catalytic Preparation of Amines. E. BRINER, P. FERRERO, and E. DE LUSERNA (*Helv. Chim. Acta*, 1924, **7**, 282—294).—Attempts were made to obtain aniline (i) by passing a mixture of benzene and ammonia vapours over a heated catalyst, (ii) from phenol and ammonia in a similar manner. From benzene and ammonia only traces of aniline could be obtained under any conditions; the observations of Wibaut are therefore confirmed (A., 1917, i, 386). The result is only to be expected, as the reaction is endothermic, $C_6H_6+NH_3=NH_2Ph+H_2-23·6$ Cal. The second reaction gives appreciable yields of aniline, up to 12% of the theoretical, the best results being obtained using alumina as catalyst at 420°, with excess of ammonia and prolonged contact. The reaction in this case is exothermic, $PhOH+NH_3=NH_2Ph+H_2O+0·4$ cal. With thoria as the catalyst, only traces of aniline are obtained, but appreciable quantities of diphenyl ether and phenylene oxide; these products are obtained also in absence of ammonia. When methyl alcohol mixed with phenol and ammonia vapours is passed over heated alumina, a mixture of methyl- and dimethyl-anilines is obtained, the former predominating, but the yields are smaller than those from phenol and ammonia alone. In presence of thoria some anisole is formed. E. H. R.

Freezing-point Curves for the System 2-Chloroacetanilide–4-Chloroacetanilide. K. J. P. ORTON and G. OWEN (*J. Chem. Soc.*, 1924, **125**, 766—767).—Owen's method (*J. Chem. Soc.*, 1923, **123**, 3393) has been applied to an examination of the freezing-point curves for the system 2-chloroacetanilide–4-chloroacetanilide. The results were in harmony with the behaviour of the system 2 : 4-dichloroacetanilide–4-chloroacetanilide, the lower-melting polymorph of 4-chloroacetanilide previously observed (*J. Chem. Soc.*, 1909, **95**, 1059) never separating from the liquid mixture in bulk but only when small quantities were cooled very slowly in capillary tubes. R. B.

Action of Hydrogen Chloride on a Dry Solution of a Chloroamine. F. G. SOPER (*J. Chem. Soc.*, 1924, **125**, 768—769).—The action of dry hydrogen chloride on a solution of 2 : 4-dichloro-*N*-chloroacetanilide in glacial acetic acid gives no trace of chlorine except in presence of moisture. This result suggests that hydrolysis, $:NCl+H_2O \rightleftharpoons :NH+HOCl$, is the first step in the production of chlorine and that the appearance of this gas is due to a subsequent interaction, $HCl+HOCl \rightleftharpoons Cl_2+H_2O$. R. B.

Solubility of Anilinesulphonic Acids. J. C. PHILIP and R. S. COLBORNE (*J. Chem. Soc.*, 1924, **125**, 492—500).—The solubility relations previously found to obtain between sulphanilic acid and water (*J. Chem. Soc.*, 1913, **103**, 284) have now been found to be characteristic of the anilinesulphonic acids generally. A notable feature of these acids is the readiness with which they form supersaturated solutions, from which under suitable conditions unstable hydrates may readily be produced. Solubility determinations show that these hydrates are not stable at any temperature on the solubility curve, but are either completely labile or are metastable over a small temperature range in the neighbourhood of 0°. Aniline-*o*-sulphonic acid forms a *monohydrate*, stable below 13·5°; above this temperature, the anhydrous acid is the stable solid phase. Aniline-*m*-sulphonic acid forms a sesquihydrate which separates below 20° as a metastable phase, with a greater solubility than that of the anhydrous acid. *p*-Bromoaniline-*o*-sulphonic acid gives, below 30°, a monohydrate which is metastable with respect to the anhydrous acid even at 0°, although its solubility can be readily measured up to 25°. *p*-Bromoaniline-*m*-sulphonic acid exists in two enantiotropic forms, the rhombic, stable above 100°, the monoclinic, stable at the ordinary temperature, and separation of the metastable monohydrate furnishes the most striking example of the class. This hydrate separates as a felted mass of crystals, which only slowly changes to the less soluble anhydrous acid. *p*-Chloroaniline-*o*-sulphonic acid with water at 0° slowly changes to a stable monohydrate, but no unstable hydrate was observed. *p*-Chloroaniline-*m*-sulphonic acid at 0° forms small tablets of a metastable monohydrate. R. B.

Chemotherapeutical Researches in the Series 205 Baeyer. Carbamates of the Aminobenzoylaminonaphthalenesulphonic Acids. E. FOURNEAU, J. TRÉFOUËL, (MME.) J. TRÉFOUËL, and J. VALLÉE (*Ann. Inst. Pasteur*, 1924, **38**, 81—114).—A more detailed account of work already noted (this vol., i, 382).

Absorption Spectra of some Derivatives of Phenol and other Substances. J. E. PURVIS.—(See this vol., ii, 219.)

Fluorescence Spectra. II. Phenol and Phenolic Ether Vapours. J. K. MARSH.—(See this vol., ii, 219.)

Action of the Oxides and the Oxy-acids of Nitrogen on Diphenyl Ether. H. RYAN and P. T. DRUMM (*Sci. Proc. Roy. Dubl. Soc.*, 1924, **17**, 313—320).—Diphenyl ether treated with nitrogen peroxide alone or in carbon tetrachloride solution, or with nitrous fumes in the same solvent, gave a mixture of *op'*- and *pp'*-dinitrodiphenyl ethers (cf. Mailhe and Murat, A., 1912, i, 346; 1913, i, 44), with some 2 : 4-dinitrophenol; with nitrous fumes in acetic acid solution, the main product was the *p*-mononitro derivative. The latter was also formed when the ether was treated with nitric acid (*d* 1·4) either alone or in carbon tetrachloride or acetic acid. With fuming nitric acid (*d* 1·5) a mixture of the *pp'*-dinitro- and 2 : 2' : 4 : 4'-*tetranitro-diphenyl ether*, m. p. 195°, was formed. This derivative was also obtained from 2 : 4-dinitrochlorobenzene and 2 : 4-dinitrophenol and by further nitration of 2 : 4-dinitrodiphenyl ether and of 2 : 4 : 4'-trinitrodiphenyl ether (cf. Cook, A., 1910, i, 731). 2 : 4 : 6-Trinitrodiphenyl ether (from picryl chloride and potassium phenoxide) and the 2 : 4 : 6 : 2'-tetranitro compound (prepared in a similar way) both gave on further nitration 2 : 4 : 6 : 2' : 4'-*pentanitrodiphenyl ether*, colourless needles, m. p. 210°. W. A. S.

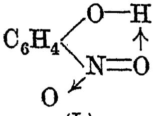
Action of the Oxides and the Oxy-acids of Nitrogen on Phenyl Benzyl Ether. H. RYAN and J. KEANE (*Sci. Proc. Roy. Dubl. Soc.*, 1924, **17**, 287—295).—Treatment of phenyl benzyl ether in the cold, and for a long time if necessary, with nitrogen peroxide, gaseous or in carbon tetrachloride solution, with nitrous fumes or with nitric acid, alone or in carbon tetrachloride solution (cf. A., 1919, i, 13; 1923, i, 323), gave mostly *p*-nitrophenyl benzyl ether, a little *p*-nitrophenyl *p*-nitrobenzyl ether (cf. Kumpf, A., 1884, 1005), and varying amounts of decomposition products. Nitration seemed not to proceed with nitric acid in acetic acid or ether solution. Further nitration of *p*-nitrophenyl benzyl ether was brought about by treatment with nitric acid in carbon tetrachloride solution, but again not in acetic acid or alcohol. The product was the above dinitro derivative. With nitric acid alone, a mixture of o-p-*dinitrophenyl* p-*nitrobenzyl ether*, colourless prisms, m. p. 207—208°, and o-p-*dinitrophenyl* o-*nitrobenzyl ether*, needles, m. p. 188°, was formed. These compounds were also obtained by treating *o*-nitrophenyl benzyl ether in a similar way. Both trinitro derivatives were converted by the action of a mixture of fuming sulphuric and nitric acids into the same product, viz. o-o-p-*trinitrophenyl* o-p-*dinitrobenzyl ether*, scales, m. p. 146°. An attempt to prepare a hexanitro derivative of the ether resulted only in the isolation of a decomposition *product*, m. p. 139—140°. W. A. S.

Action of the Oxides and the Oxy-acids of Nitrogen on Diphenyl Ethylene Ether. H. RYAN and T. KENNY (*Sci. Proc. Roy. Dubl. Soc.*, 1924, **17**, 305—311).—Diphenyl ethylene ether, $Ph{\cdot}O{\cdot}C_2H_4{\cdot}O{\cdot}Ph$, treated with gaseous nitrogen peroxide, or nitrogen peroxide in carbon tetrachloride solution, or with nitric acid (*d* 1·5), alone or in carbon tetrachloride solution, gave mostly the *pp'*-dinitro derivative, m. p. 143° (cf. Weddige, A., 1881, 1136), accompanied by 2 : 4-dinitrophenol and decomposition products. Nitration did not take place with nitric acid dissolved in acetic acid. *Phenyl* o-*nitrophenyl ethylene ether*, rectangular plates, m. p.

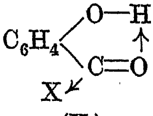
97°, and the corresponding p-*nitro* derivative, prisms, m. p. 86°, were prepared by interaction of the corresponding potassium nitrophenoxide and ω-bromophenetole. Di-*o*-nitrophenyl ethylene ether was prepared similarly (Weddige, *loc. cit.*). From the *o*-nitro and this di-*o*-nitro derivative, by further nitration, o-*nitrophenyl* o-p-*dinitrophenyl ethylene ether*, m. p. 172°, was obtained. All these lower nitrated derivatives gave ultimately *di*-2 : 4-*dinitrophenyl ethylene ether*, pale yellow, flat prisms, m. p. 214°, and continued action of nitric acid destroyed the molecule. o-*Nitrophenyl* p-*nitrophenyl ethylene ether*, rectangular prisms, m. p. 117·5°, was also prepared synthetically. W. A. S.

Solubility of the Aminophenols. N. V. SIDGWICK and R. K. CALLOW (*J. Chem. Soc.*, 1924, **125**, 522—527).—As regards solubility in water and benzene, the aminophenols are an abnormal group, their abnormality resembling that of the phenylenediamines (*Chem. Soc. Trans.*, 1923, **123**, 2817) rather than the usual type. The *o*-compound is less soluble in water than the *p*-isomeride; in benzene, the solubilities are about the same. The *m*-compound is more soluble in water and less soluble in benzene than either of its isomerides. *m*-Aminophenol very readily forms supersaturated solutions in water, consequently it was possible to follow the two-liquid curve up to 60—70° below the saturation point, and even to measure the metastable ice curve in dilute solutions. This appears to be a general property of *m*-derivatives (cf. *Chem. Soc. Trans.*, 1922, **121**, 2256). The following boiling points were determined at 11 mm. pressure: *m*-aminophenol, 164° (with very slight decomp.); *p*-aminophenol, 174° (after melting with decomp.). *o*-Aminophenol sublimes rapidly at 153°. (Cf. following abstract.) R. B.

Abnormal Benzene Derivatives. N. V. SIDGWICK and R. K. CALLOW (*J. Chem. Soc.*, 1924, **125**, 527—538).—The results of a series of investigations (*Chem. Soc. Trans.*, 1915, **107**, 1202; 1920, **117**, 389, 396; 1921, **119**, 979, 1001, 1013; 1922, **121**, 1844, 1853, 2256, 2263, 2586; 1923, **123**, 2813, 2819, and preceding abstract) on the volatility and solubility in the liquid state of certain classes of benzene derivatives are summarised and a possible explanation of the phenomena is discussed. The benzene derivatives in question are described as abnormal because the isomerides differ widely in their vapour pressures and solubility relations. Such abnormality depends on the presence in the molecule of two active or alterable substituents (OH, CO_2H, NH_2, CHO, NO_2, Cl, etc., as opposed to unalterable such as the alkyls) and of these two, one must be OH, NH_2 (or substituted NH_2), or CO_2H. Apparently one group makes the compound sensitive and the other augments this sensitiveness. The relations holding among the substituted phenols differ in many respects from those observed with the amines and acids, which again differ from one another. Among the phenols, abnormality was found in all cases examined where the second substituent was other than alkyl. The meta- and para-compounds resemble one another closely as normal isomerides, but differ markedly from the ortho-compounds in being (*a*) less volatile,



(I.)



(II.)

(*b*) more miscible with water, and (*c*) less miscible with benzene, properties characteristic of polar as opposed to non-polar substances. Consideration of other properties confirms the view that the ortho-series is abnormal and from the fact that in these compounds the polar character due to the hydroxylic hydrogen is suppressed in much the same way as if this hydrogen were replaced by methyl, the suggestion is put forward of a co-ordinate linking of the phenolic hydrogen with some atom of the second group. This is expressed in the annexed formulæ, in which the arrow (→) points to the atom receiving the two unshared electrons. These formulæ represent the most stable type of chelate ring known, and formula (II) explains the abnormality of the hydroxybenzoic acids, their esters and aldehydes (X=OH, OAlk, or H). With other active groups (halogens, OH, OAlk, and perhaps NH_2), a five-atom ring must be assumed,  $C_6H_4<\begin{smallmatrix}Cl\searrow\\ O\nearrow\end{smallmatrix}H$ or  $C_6H_4<\begin{smallmatrix}O\searrow\\ O\nearrow\\ H\end{smallmatrix}H$, which is less common, but occurs in the cupferron compounds and is possible in a large class of mordant dyes. Such chelate compounds always tend to be non-polar (cf. acetylacetones) and this ring structure explains why *o*-nitrophenol cannot form compounds with aniline, *p*-toluidine, benzamide, and acetamide, whereas the *m*- and *p*-nitrophenols can; and why if the phenol has an active substituent both in the ortho- and in the para-positions, the influence of the ortho-group predominates and the compound is non-polar. An explanation is also afforded of Auwers' conclusion (A., 1903, ii, 268) that a substituent group which when occupying the ortho-position in a solute gives abnormality, for example, in benzene solution, when introduced into the solvent tends to reduce the abnormality. The behaviour of abnormal derivatives other than phenol is much less easy to explain, and co-ordination through the hydrogen atom is only one of several possibilities. With the chloro- and nitro-acids, the difference between meta- and para-compounds is as great as that between the meta- and ortho-, whilst solubilities both in water and in benzene are in the order $o>m>p$. The amino-compounds are somewhat less abnormal, and this is probably connected with their basicity. The introduction of an acetyl group into the chloro- and nitro-anilines tends to increase the abnormality. Among the amino-compounds the meta-derivative occupies an exceptional position, being less volatile than the para-derivative, and its solubility both in benzene and in water is much nearer to (and sometimes less than) the ortho- than is the case with the other classes of abnormal benzene derivatives, a distinction which points to direct chemical influence rather than to either ring-formation or steric effect. R. B.

Action of the Oxides and Oxy-acids of Nitrogen on β-Naphthyl Ethyl Ether. H. Ryan and J. Keane (*Sci. Proc. Roy. Dubl. Soc.*, 1924, **17**, 297—303).—β-Naphthyl ethyl ether on treatment with nitrogen peroxide, nitrous fumes, or nitric acid in glacial acetic acid or carbon tetrachloride solution, gave mainly 1-nitro-2-naphthyl ethyl ether, and with gaseous nitrogen peroxide or nitric acid (more than before) in carbon tetrachloride solution or alone, a mixture of 1 : 6- and 1 : 8-dinitro-2-naphthyl ethyl ether. The ether itself, its 1-nitro-, 1 : 6-dinitro-, and 1 : 8-dinitro-derivatives were all converted by the further action of nitric acid into 1 : 6 : 8-*trinitro-2-naphthyl ethyl ether*, colourless prisms or scales, m. p. 189—190° (cf. Staedel, A., 1883, 863), the constitution of which was thus proved. Heated with alcoholic ammonia, it gave 1 : 6 : 8-trinitro-β-naphthylamine, m. p. 300—301°. W. A. S.

Conversion of Eugenol into *iso*Eugenol. S. K. Gokhale, J. J. Sudborough, and H. E. Watson (*J. Indian Inst. Sci.*, 1923, 6, 241—255).—The composition of mixtures of eugenol and *iso*-eugenol is best estimated from the refractive index. The earlier method (McKie, *Chem. Soc. Trans.*, 1921, **119**, 777) is troublesome and untrustworthy. Eugenol has n_D^{30} 1·53664 and *iso*eugenol n_D^{30} 1·57237. The curve showing the relationship between composition and refractive index for mixtures is a straight line. The temperature coefficient of the refractive index is about 0·0004 per degree for both substances.

When eugenol is fused with sodium hydroxide at 200—210°, little if any conversion and much decomposition takes place; with potassium hydroxide (4 parts), 85% of the theoretical yield of *iso*eugenol is obtained (cf. Einhorn and Frey, A., 1894, i, 578). A mixture of 2 parts of sodium hydroxide and 1 part of potassium hydroxide also gives a good yield. When eugenol is heated with 6 to 8 parts of 50% potassium hydroxide solution in an autoclave at 170—180°, almost complete conversion takes place. W. A. S.

Adrenaline Compounds. C. Funk and L. Freedman (U. S. Pat. 1472298).—β-*Methylamino*-4-α-*ethoxyethylpyrocatechol hydrochloride*, thin, rectangular prisms, m. p. 169°, is prepared by heating *r*-adrenaline (or its hydrochloride) for several hours in a reflux apparatus with absolute ethyl alcohol containing dry hydrogen chloride equivalent to 1—4 mols. of adrenaline, and cooling. A *substance* (*hydrochloride*, rectangular prisms, m. p. 180—183°), possibly a lactonic compound of 2 mols. of adrenaline, is also formed.

Chemical Abstracts.

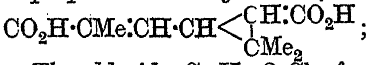
Properties of Neighbouring Hydroxy Groups Attached to a Benzene Nucleus. R. L. Alimchandani (*J. Chem. Soc.*, 1924, **125**, 539—543).—The hypothesis that the carbon atoms of the benzene nucleus are charged alternately positively and negatively finds support in the properties of the three vicinal methoxy groups of 3 : 4 : 5-trimethoxy-2-trichloromethylphthalide and 3 : 4 : 5-trimethoxybenzenesulphonic acid. When chloral hydrate is condensed with 3 : 4 : 5-trimethoxybenzoic acid by means of 90% sulphuric acid, the product consists mainly of 3 : 4 : 5-trimethoxy-2-trichloromethylphthalide, rectangular plates, m. p. 76—77°, from which the simultaneously formed 4-hydroxy-3 : 5-dimethoxy-2-trichloromethylphthalide is separated by means of dilute sodium hydroxide. The trimethoxyphthalide by treatment with 98% sulphuric acid is converted into 4-hydroxy-3 : 5-dimethoxy-2-trichloromethylphthalide, m. p. 172—173°, and with sodium hydroxide into 3 : 4 : 5-trimethoxyphthalide-2-carboxylic acid, m. p. 147—149°. Hydrolysis of this acid with 96—98% sulphuric acid gives 4-hydroxy-3 : 5-dimethoxyphthalide-2-carboxylic acid. 3 : 4 : 5-Trimethoxyphthalide similarly yields 4-hydroxy-3 : 5-dimethoxyphthalide, m. p. 144°. The action of 96—98% sulphuric acid on pyrogallyl trimethyl ether gives in varying proportions 3 : 4 : 5-*trimethoxybenzenesulphonic acid*, leaflets, containing $1{\cdot}5H_2O$, m. p. 95—97° (the *barium*, *sodium*, and potassium salts are described), and 4-*hydroxy*-3 : 5-*dimethoxybenzenesulphonic acid*, leaflets, $1{\cdot}5H_2O$, m. p. 128—129° (the *barium* and sodium salts are described), which is not hydrolysed by sulphuric acid even in hot solution and on oxidation yields 2 : 6-dimethoxy-*p*-benzoquinone. Treatment with bromine gives 1 : 2 : 3-*tribromo*-5-*hydroxy*-4 : 6-*dimethoxybenzene*, slender prisms, m. p. 134—135°, which by methylation with methyl sulphate gives 1 : 2 : 3-tribromo-4 : 5 : 6-trimethoxybenzene, prisms, m. p. 75—76°. This compound was also obtained by the action of bromine on 3 : 4 : 5-trimethoxybenzenesulphonic acid, the sulphonic group being displaced. Hydrolysis of the trimethoxybenzenesulphonic acid to pyrogallyl trimethyl ether readily takes place in hot sulphuric acid. R. B.

Methyl Ether of Diphenylphenylacetylenylcarbinol. K. Ziegler and K. Tripp (*Ber.*, 1924, **57**, [*B*], 420; cf. A., 1923, i, 921).—The carbinol is readily methylated by dissolving it in hot methyl alcohol and adding 1 to 2% of sulphuric acid, previously diluted with methyl alcohol. On cooling, the methyl ether crystallises out almost quantitatively, and after recrystallisation forms leaflets, m. p. 123—124°. It is decomposed by acids to give phenyl β-phenylstyryl ketone, m. p. 86—87° (cf. A., 1922, i, 556). F. A. M.

Benzeins. R. Meyer and W. Gerloff (*Ber.*, 1924, **57**, [*B*], 591—599; cf. A., 1923, i, 230).—Benzaurin dissolves in aqueous alkali to an intense carmine solution which gradually fades; the fading is not due to atmospheric action as suggested by Doebner (*Ber.*, 1879, **12**, 1464), but probably to the transformation of coloured *p*-hydroxyfuchsone into colourless dihydroxytriphenylcarbinol. On passing carbon dioxide into the colourless solution, the original benzaurin is reprecipitated. It is considered to be *p*-hydroxyfuchsone hydrate, $OH{\cdot}C_6H_4{\cdot}CPh{:}C_6H_4{:}O,H_2O$. Benzaurin forms a crystalline *bisulphite* compound, $(OH{\cdot}C_6H_4)_2C(Ph)SO_3Na$, which decomposes on keeping. It was not found possible to prepare an oxime, phenylhydrazone, or semicarbazone. Treatment of an alkaline solution of benzaurin with potassium cyanide gave the *nitrile*, $(OH{\cdot}C_6H_4)_2C(Ph)CN$, an oil which slowly solidified to crystals, m. p. 203—204°; attempts to hydrolyse the nitrile to the corresponding dihydroxytriphenylmethanecarboxylic acid were unsuccessful. On treatment with acetic anhydride, the nitrile yielded a *diacetyl* derivative, colourless crystals, m. p. 140—141°, and on benzoylation gave *dihydroxytriphenylmethanecarboxylamide dibenzoate*, $(OBz{\cdot}C_6H_4)_2C(Ph)CONH_2$; on hydrolysing this with alcoholic potassium hydroxide and acidifying the resultant solution, the original nitrile was recovered. *Benzaurin diethyl ether* and *dibenzyl ether* are colourless, crystalline substances melting at 75—76° and 110°, respectively. Bromination of benzaurin in acetic acid in presence of iron gives *tetrabromobenzaurin*, dark red crystals which lose no water on moderate heating (*sodium* salt, brown needles with green iridescence). Benzaurin is reduced by alcoholic ammonia to *pp'*-diaminotriphenylmethane; using strong aqueous ammonia, *p*-aminofuchsonimine is formed.

Resorcinolbenzein dried in a vacuum has the formula $C_{19}H_{14}O_4$. At 140°, it loses 1 mol. of water, leaving a product, $C_{19}H_{12}O_3$, as found by Kehrmann; the authors therefore give the hydrated substance the formula  $OH{\cdot}C_6H_3{<}\overset{O\text{—}}{\underset{CPh}{}}{>}C_6H_3{\cdot}O\ .\ .\ .\ H_2O$. The following derivatives of resorcinolbenzein were prepared: *diacetate*, yellow needles, m. p. 145°; *dibenzoate*, colourless needles, m. p. 152°; dibromo derivative, reddish-yellow powder which loses H_2O at 140°; tetrabromo derivative, crystals which lose 1 mol. of HBr at 140—150°; *pentabromo* derivative, brown needles, which sublime with decomposition at 140—150° (*sodium salt*, brownish-red needles with green iridescence). *Dinitroresorcinolbenzein nitrate*, obtained by warming the benzein with strong nitric acid, forms a brilliant red, crystalline powder which decomposes with a slight explosion on heating. F. A. M.

Insecticides. II. Constitution of Chrysanthemum-mono- and -di-carboxylic Acids. H. STAUDINGER and L. RUZICKA (*Helv. Chim. Acta*, 1924, 7, 201—211).—Three acids were obtained by hydrolysis of the semicarbazones of the active constituents of insect powder (cf. p. 523). The first, chrysanthemumcarboxylic acid, $C_{10}H_{16}O_2$, is readily separated from the others on account of its volatility in steam, and is shown to be 2 : 2-*dimethyl*-3-iso*butenyl*cyclo*propane*-1-*carboxylic acid*,  $CMe_2{:}CH{\cdot}CH{<}\begin{matrix}CMe_2\\ |\\ CH{\cdot}CO_2H\end{matrix}$, $[\alpha]_D^{20}$ +20·1°. Its *methyl* ester is a colourless liquid, b. p. 99°/14 mm., 86—87°/10 mm., $[\alpha]_D^{20}$ +20·74°, having a faint odour of insect powder; *chloride*, $C_{10}H_{15}OCl$, colourless oil, b. p. 85°/12 mm., 58°/0·03 mm.; *anilide*, white needles, m. p. 101°; *amide*, white needles, m. p. 131°; *anhydride*, viscous oil, b. p. 125°/15 mm. When reduced by the Paal-Skita method, the acid takes up two atoms of hydrogen, giving 2 : 2-*dimethyl*-3-iso*butyl*cyclo*propane*-1-*carboxylic acid*, a colourless, mobile oil, b. p. 124—126°/10 mm. Its *chloride* has b. p. 89—90°/12 mm.; *amide*, white crystals, m. p. 132—132·5°; and *anilide*, large, colourless crystals, m. p. 82—83°. *Methyl* 1-trans-*caronate*, $C_9H_{14}O_4$, obtained by decomposing chrysanthemumcarboxylic acid ozonide, forms a mass of white crystals, m. p. 37—38°, b. p. 93°/25 mm., $[\alpha]_D$ −8·26° in benzene. The second acid obtained from insect powder, chrysanthemumdicarboxylic acid, has the composition $C_{10}H_{14}O_4$, and the third, $C_{11}H_{16}O_4$, is its monomethyl ester. It is the latter which is present in the active constituent of the insect powder, the former being formed from it by hydrolysis. By the action of ozone, the second acid gives *l-trans*-caronic acid and pyruvic acid, whilst the third gives *l-trans*-caronic acid and methyl pyruvate. Chrysanthemumdicarboxylic acid is therefore 2 : 2-*dimethyl*-3-β-*carboxypropenyl*cyclo*propane*-1-*carboxylic acid*,



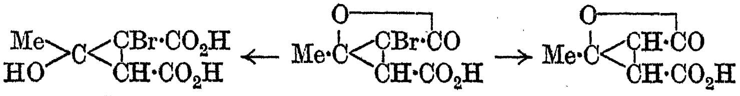
$$CO_2H\cdot CMe{:}CH\cdot CH{<}\begin{matrix}CH\cdot CO_2H\\ |\\ CMe_2\end{matrix};$$

it has $[\alpha]_D^{17}$ +72·8°. The *chloride*, $C_{10}H_{12}O_2Cl_2$, forms white crystals, m. p. 48—50°, b. p. 151°/12 mm.; *anilide*, m. p. 204—205°. The *monomethyl* ester,  $\begin{matrix}CMe_2\\ |\\ CO_2H\cdot CH\end{matrix}{>}CH\cdot CH{:}CMe\cdot CO_2Me$, is a viscous oil, b. p. 129—130°/0·03 mm., $[\alpha]_D^{18}$ +103·9°; the *chloride* is a colouroil, b. p. 114°/0·5 mm. The *dimethyl* ester is a colourless oil, b. p. 149°/16 mm., 87—88°/0·25 mm. When chrysanthemumdicarboxylic acid is distilled at atmospheric pressure, it partly decomposes into carbon dioxide and 2 : 2-*dimethyl*-3-*propenyl*cyclo*propane*-1-*carboxylic acid*, a mobile oil, b. p. 133°/12 mm.; *chloride*, b. p. 95°/12 mm. With pyrethrolone, this acid forms an ester having weak insecticidal properties. The ester obtained from reduced chrysanthemumcarboxylic acid and pyrethrolone is inactive. E. H. R.

3-Methyl*cyclo*propene-1 : 2-dicarboxylic Acid. F. FEIST (*Annalen*, 1924, **436**, 125—153; cf. Feist, A., 1893, i, 404; Goss, Ingold, and Thorpe, *J. Chem. Soc.*, 1923, **123**, 327).—When bromo*iso*dehydracetic acid is treated with alkali, an acid (A) is produced, m. p. 200°, which on dibromination and reduction with sodium amalgam yields an isomeride (B), m. p. 189°. Only one formula is possible for both these isomeric methyl*cyclo*propenedicarboxylic acids, namely,  $CMe{<}\begin{matrix}CH\cdot CO_2H\\ |\\ C\cdot CO_2H\end{matrix}$, since both are racemic acids which can be resolved into their optically active components. The acid A (*silver* salt, and *phenylhydrazine* salt, white needles, m. p. 138°) was resolved by means of its quinine salt into *d*- and *l*-acids having the rotations $[\alpha]_D$ +215° and −156°. They both melt at 200°. The methyl ester, needles, m. p. 32°, has b. p. 122°/20 mm., d_4^{20} 1·142, n_D^{20} 1·4672. The ethyl ester, m. p. 38°, b. p. 135°/15 mm., the *anilide*, white powder, m. p. 246°, and *carbamide* salt, m. p. 215°, are described.

The acid B was resolved by means of its brucine and quinine salts; the extreme values obtained for the *d*- and *l*-acids were $[\alpha]_D$ +179·8° and −118°. The methyl ester of B has m. p. 30·5° and b. p. 116°/20 mm.; d_4^{20} 1·140, n_D^{20} 1·4669. It is not identical with the methyl ester of A and on hydrolysis regenerates B. The latter is converted into A by concentrated sulphuric acid or by heating with concentrated alkali.

By dibromination of the acids or their esters and subsequent reduction with sodium amalgam, B is produced. The dibromo-acid derived from A melts at 244° and gives an *ethyl* ester, b. p. 183—184°/13 mm., d_4^{20} 1·590, n_D^{20} 1·5026. The *methyl* ester forms white needles, m. p. 77°. The dibromo-acid derived from B melts at 232° and yields an *ethyl* ester, b. p. 177°/13 mm., d_4^{20} 1·566, n_D^{20} 1·500. This dibromo-acid on warming with water or concentrated alkali yields a monobasic lactonic acid, $C_6H_5O_4Br$, m. p. 171°, *2-bromo-3-hydroxy-3-methyl*cyclo*propane-*1 : *3-dicarboxylolactonic acid* (I), which is readily transformed by alkali into the corresponding hydroxy-acid, $C_6H_7O_5Br$ (II). The *methyl* ester of the lactonic acid has m. p. 98°, b. p. 166°/15 mm. By reduction of the lactonic acid with sodium amalgam, bromine is removed and the lactone of so-called oxalbutyric acid, m. p. 140—141°, is left (III).



(II.) (I.) (III.)

The lactonic acid (m. p. 171°) is identical with the lactone of so-called oxalbromobutyric acid. On oxidation with alkaline permanganate, it yields a tribasic *acid*, $C_6H_5O_6Br$ (m. p. 225°), which gives a *dimethyl* ester, m. p. 76°.

Reduction of 3-methyl*cyclo*propene-1 : 2-dicarboxylic acids (A or B) by means of colloidal palladium and hydrogen yields two isomeric 3-methyl*cyclo*propane-1 : 2-dicarboxylic acids (m. p. 147° and 108°). A third isomeride, m. p. 138—140°, has also been obtained as a by-product in the reduction of the dibromomethyl*cyclo*propanedicarboxylic acid by means of sodium amalgam. Of the three possible isomerides, two have been already described, one, m. p. 108°, by Preiswerk (A., 1903, i, 459), and the other by Kötz and Stalmann (A., 1903, i, 741), who isolated a syrup. The acid, m. p. 147°, is thought to be the *trans* acid, as it gives no anhydride. The methyl ester has b. p. 208·5—209°/760 mm., 100°/14 mm., and on hydrolysis yields an acid, m. p. 138°. The acid, m. p. 147°, after exposure to moisture melts at 138°, but after drying its melting point rises to 147°. Acid A gives an *ozonide*, $C_6H_6O_7$ (horny solid), which on hydrolysis yields oxalic and acetic acids, through acetyloxalacetic acid. The methyl ester gives an *ozonide* (colourless oil) which on hydrolysis yields methyl acetoacetate and methyl oxalacetate.

Anhydrides. W. AUTENRIETH and G. THOMAE. (See i, 485).

Constitution of Sparassol. A. ST. PFAU (*Ber.*, 1924, 57, [*B*], 468—470).—The product, m. p. 67—68° (sparassol), obtained by Wedekind and Fleischer (this vol., i, 174) from the fungus *Sparassis ramosa*, is proved to be identical with a product obtained by Pfau from a fungus, *Evernia prunastri*. It is identical with the methyl ester of everninic acid, 6-hydroxy-4-methoxy-*o*-toluic acid, and is not methyl 4-hydroxy-6-methoxy-*o*-toluate as suggested by Wedekind and Fleischer. Sparassol does not exist as such in the fungus, but is formed by the alcoholysis of the evernic acid present. On hydrolysis with 10% aqueous sodium hydroxide, sparassol yields everninic acid. F. A. M.

Sparassol. E. Späth and K. Jeschki (*Ber.*, 1924, **57**, [*B*], 471–474; cf. preceding abstract).—The constitution of sparassol was proved in the following manner. Orcinol was converted into orcylaldehyde by the method of Gattermann and Köbner (A., 1899, i, 363) and this into orsellinic acid (4 : 6-dihydroxy-*o*-toluic acid). The last was methylated by means of diazomethane to the 4-methyl ether of methyl orsellinate (methyl everninate), which melted at 67—68° and was identical with Wedekind and Fleischer's sparassol. The *acetyl* derivative (*acetylsparassol*) has m. p. 63—64°. The *dimethyl* ether of methyl orsellinate has m. p. 41—42°, and the *nitro* derivative of methyl everninate, m. p. 168—169°. F. A. M.

Physical Constants of Stereoisomeric Compounds. K. von Auwers and B. Ottens (*Ber.*, 1924, **57**, [*B*], 437—446).—Systematic investigation of the benzenoid hydrocarbons (cf. A., 1916, i, 130; 1919, i, 578) and of derivatives of *cyclo*hexane (A., 1920, i, 721) has shown that the propinquity of side chains or other substituents to one another causes an increase in density and index of refraction and a decrease in molecular refractivity. It is to be expected, therefore, that the *cis*-forms of stereoisomeric compounds as a consequence of the closer juxtaposition of their substituents would resemble the ortho- or 1 : 2-derivatives and have a higher density and refractive index but a lower molecular refraction than their *trans*-isomerides. This hypothesis has already been utilised to some extent in the elucidation of the configuration of compounds (cf. Skita, A., 1920, i, 27; 1923, i, 671; Hückel, this vol., i, 31); its general validity is now tested by an examination of several well-defined pairs of isomerides.

Ethyl hexahydrophthalate and ethyl 4-amino-2 : 6 : 6-trimethylhexahydrobenzoate exhibit well-marked differences which are in harmony with the rule mentioned above; with the ethyl esters of hexahydroterephthalic and hexahydrohomophthalic acids, the differences are so slight as to be inconclusive, whilst with the ethyl hexahydro*iso*phthalates the slight differences are contrary to the rule. The latter observation, combined with the experience of Skita (A., 1923, i, 671), indicates that for the present physical data cannot be regarded as trustworthy aids in elucidating the configuration of meta- or 1 : 3-derivatives. The values observed with trithioaldehyde and trithioacetone are in harmony with those which are anticipated; this is also the case with the isomeric βε-dihydroxy-βε-dimethyl-Δγ-hexenes, $OH\cdot CMe_2\cdot CH{:}CH\cdot CMe_2\cdot OH$ (cf. Zalkind, A., 1923, i, 176). The stereoisomeric dimethylsuccinic and dimethylglutaric esters show similar small, scarcely utilisable differences in their constants such as are observed with the hydrogenated tere- and homo-phthalic esters. The further accumulation of methyl groups in the succinic molecule produces the expected effects. The physical constants of pairs of stereoisomeric alkyl-glutaconic esters are very similar. This is to be expected if Feist's view that these substances are geometrical isomerides is accepted, since marked differences in the spectroscopic constants are only observed with simple, stereoisomeric acids and esters of the acrylic series, and these tend to disappear as the molecule becomes more complicated, even to only a limited extent. On the other hand, exaltations such as would be expected if Thorpe's formulation is adopted are not observed.

Physical constants are recorded for the following compounds. *Ethyl* cis-*hexahydrophthalate*, b. p. 133°/10 mm., d_4^{20} 1·054, $n_\alpha^{13{\cdot}9}$ 1·45296, n_{He}^{20} 1·453. *Ethyl* trans-*hexahydrophthalate*, b. p. 135°/11 mm., d_4^{20} 1·040, n_{He}^{20} 1·450. *Ethyl* cis-*hexahydro*iso*phthalate*, b. p. 142°/11 mm., d_4^{20} 1·045, n_{He}^{20} 1·452. *Ethyl* trans-*hexahydro*iso*phthalate*, b. p. 142°/12 mm., d_4^{20} 1·047, n_{He}^{20} 1·453. *Ethyl* cis-*hexahydroterephthalate*, b. p. 151°/13 mm., $d_4^{20{\cdot}6}$ 1·0516, $n_{\mathrm{He}}^{20{\cdot}6}$ 1·45222. *Ethyl* trans-*hexahydroterephthalate*, lustrous, flattened needles, m. p. 43—44°, $d_4^{64{\cdot}4}$ 1·0105, $n_{\mathrm{He}}^{64{\cdot}4}$ 1·43367. *Ethyl* cis-*hexahydrohomophthalate*, b. p. 273°, d_4^{20} 1·040, n_{He}^{20} 1·454. *Ethyl* trans-*hexahydrohomophthalate*, b. p. 275°, d_4^{20} 1·038, n_{He}^{20} 1·453. Ethyl *cis*-4-amino-2 : 6 : 6-trimethylhexahydrobenzoate, b. p. 127°/11 mm., d_4^{20} 0·990, n_{He}^{20} 1·475. Ethyl *trans*-4-amino-2 : 6 : 6-trimethylhexahydrobenzoate, b. p. 127°/11 mm., d_4^{20} 0·980, n_{He}^{20} 1·473.

Ethyl succinate, b. p. 217°, d_4^{20} 1·041, n_{He}^{20} 1·420. Ethyl methylsuccinate, b. p. 218°, d_4^{20} 1·011, n_{He}^{20} 1·419. Ethyl *cis*-αβ-dimethylsuccinate, b. p. 221°, d_4^{20} 0·996, n_{He}^{20} 1·423. Ethyl *trans*-αβ-dimethylsuccinate, b. p. 220°, d_4^{20} 0·995, n_{He}^{20} 1·421. Ethyl αα-dimethylsuccinate, b. p. 218°, d_4^{20} 0·993, n_{He}^{20} 1·421. *Ethyl trimethylsuccinate*, b. p. 226°, d_4^{20} 0·993, n_{He}^{20} 1·436. Ethyl tetramethylsuccinate, b. p. 219°, d_4^{20} 0·995, n_{He}^{20} 1·436. *Ethyl* cis-αγ-*dimethylglutarate*, b. p. 231°, d_4^{20} 0·980, n_{He}^{20} 1·423. *Ethyl* trans-αγ-*dimethylglutarate*, b. p. 231°, d_4^{20} 0·977, n_{He}^{20} 1·422.

Ethyl *cis*-β-methylglutaconate, b. p. 131°/19 mm., d_4^{20} 1·034, n_{He}^{20} 1·452. Ethyl *trans*-β-methylglutaconate, b. p. 127°/12 mm., d_4^{20} 1·034, n_{He}^{20} 1·452. Ethyl *cis*-αβ-dimethylglutaconate, b. p. 128°/13 mm., d_4^{20} 1·024, n_{He}^{20} 1·454. Ethyl *trans*-αβ-dimethylglutaconate, b. p. 125°/12 mm., d_4^{20} 1·031, n_{He}^{20} 1·454. Ethyl *cis*-α-ethyl-β-methylglutaconate, b. p. 127°/12 mm., d_4^{20} 1·019, n_{He}^{20} 1·455. Ethyl *trans*-α-ethyl-β-methylglutaconate, b. p. 139°/18 mm., d_4^{20} 1·014, n_{He}^{20} 1·453.

Trithioacetone, $C_9H_{18}S_3$, has m. p. 22°, d_4^{20} 1·068, n_{He}^{20} 1·542. *cis*-Trithioacetaldehyde, m. p. 101°, and *trans*-trithioacetaldehyde, m. p. 126°, in addition to trithioacetone have been examined in quinoline solution; the solvent is shown to be suitable for this purpose.

cis-βε-Dihydroxy-βε-dimethylhexene, m. p. 76°, d_4^{99} 0·869, n_{He}^{99} 1·423. *trans*-βε-Dihydroxy-βε-dimethylhexene, m. p. 69°, d_4^{99} 0·864, n_{He}^{99} 1·422.

H. W.

Synthesis of Polyhydroxyphenylalanines. F. SCHAAF and A. LABOUCHÈRE (*Helv. Chim. Acta*, 1924, 7, 357—363).—For the synthesis of 2 : 5-dihydroxyphenylalanine, gentisaldehyde dimethyl ether (2 : 5-dimethoxybenzaldehyde) was condensed with hippuric acid, and the resulting α-benzoylamino-2 : 5-dimethoxycinnamic acid reduced to α-benzoylamino-2 : 5-dimethoxy-β-phenylpropionic acid, from which the 2 : 5-dihydroxyphenylalanine was obtained. This method was inapplicable for the synthesis of trihydroxyphenylalanine as the cinnamic acid derivative could not be reduced. The following method was, however, successful. 2 : 3 : 4-*Trimethoxybenzaldehyde* was obtained by Gattermann's synthesis from pyrogallol and hydrocyanic acid; it forms glistening prisms, m. p. 37°. It condenses with hydantoin to give 2 : 3 : 4-*trimethoxybenzylidenehydantoin*,  $C_6H_2(OMe)_3CH{:}C<\begin{matrix}NH\cdot CO\\ CO-NH\end{matrix}$, pale yellow needles, m. p. 197°, which is reduced by sodium amalgam in water to 2 : 3 : 4-*trimethoxybenzylhydantoin*, thin, white needles, m. p. 154°. This is hydrolysed by boiling barium hydroxide to 2 : 3 : 4-*trimethoxyphenylalanine*, forming star-shaped aggregates of needles, m. p. 216°. If the hydrolysis is not carried to completion, *α-carbamido-*β-2 : 3 : 4-*trimethoxyphenylpropionic acid* is obtained, m. p. 189°. The trimethoxyphenylalanine is demethylated by boiling with hydriodic acid (*d* 1·70), giving 2 : 3 : 4-*trihydroxyphenylalanine*, crystallising in short, stout needles, m. p. 225° (decomp.). Its neutral solution reduces silver nitrate in the cold and gives a permanent blue colour with ferric chloride.

3 : 4 : 5-*Trihydroxyphenylalanine* was synthesised in a similar manner. It forms stout prisms, m. p. 290° (decomp.). In its low solubility it resembles 3 : 4-dihydroxyphenylalanine, but both the trihydroxyphenylalanines differ from this in not giving the characteristic reaction with the pigment-forming ferment, dopaoxydase. 3 : 4 : 5-*Trimethoxybenzylidenehydantoin* forms yellow needles, decomp. 250—260°; 3 : 4 : 5-*trimethoxybenzylhydantoin*, long, white prisms, m. p. 172°; 3 : 4 : 5-*trimethoxyphenylalanine*, white needles, decomp. 220°. E. H. R.

Constitution of Phthalonic Acid. CORNILLOT (*Compt. rend.*, 1924, **178**, 713—715; cf. this vol., i, 294).—Phthalonic anhydride (1 mol.) is converted by phosphorus pentachloride (1 mol.), in presence of toluene, into *α-chlorophthalide-α-carboxylic chloride*,  $CO<\begin{matrix}C_6H_4\\ O\end{matrix}>CCl\cdot COCl$, prisms, m. p. 70°, b. p. 120°/2 mm. The latter in moist air passes into the corresponding *acid*, white needles, m. p. 133°. The acid is stable in air; cold alkali slowly, and warm alkali very rapidly, affords phthalonic acid. The chloro-acid, or its chloride, is at once converted by alcohols into the corresponding esters. The *methyl* ester, stable, has m. p. 92°; the *ethyl* ester, m. p. 48°, b. p. 164°/5 mm., is gradually affected by moist air. The chloride, with aniline, affords the corresponding *anilide* (m. p. 137·5°), this being converted by concentrated alkali into phthalonanilic acid.

Phthalonic anhydride and methyl alcohol afford *methyl hydrogen phthalonate*, $C_6H_4(CO_2H)\cdot CO\cdot CO_2Me$, m. p. 94°; this ester separates from alcoholic solutions with 1 mol. of solvent of crystallisation (removable in a vacuum), and is converted by phosphorus pentachloride into methyl α-chlorophthalide-α-carboxylate. E. E. T.

Isomerism of the Oximes. XVI. Action of Ultra-violet Light on Aldoximes and their Derivatives. O. L. Brady and G. P. McHugh (*J. Chem. Soc.*, 1924, **125**, 547—554).—The action of ultra-violet light on nineteen aromatic aldoximes has been investigated. In nine cases, viz., *p*-methoxy- and 3 : 4-methylenedioxybenz*anti*aldoximes, benz*anti*aldoxime, *o*-, *m*-, and *p*-nitro-, and *o*-, *m*-, and *p*-chloro-benz*anti*aldoximes, conversion from the *anti*- to the *syn*-isomeride was accomplished, but in all these cases the *syn*-isomeride has been prepared by other means. It is evident, however, that the conversion is not dependent, as Ciusa supposed (A., 1907, i, 137), on the presence of a negative substituent in the benzene ring. Eight cases were examined in which the *syn*-isomeride had not been prepared by other means: *o*-methoxy-, 5-bromo-*o*-methoxy-, 2 : 4-dinitro-, 3-nitro-*p*-dimethylamino-, 6-nitro-3 : 4-methylenedioxy-, 5-nitro-3 : 4-dimethoxy-, 6-nitro-3 : 4-dimethoxy-, and 5-bromo-4-hydroxy-3-methoxy-benz*anti*aldoximes, and in no case did conversion take place under the influence of ultra-violet light. With 3 : 4-dimethoxybenz*anti*aldoxime no isomeric change occurred, although the *syn*-compound has been obtained by special means. 5-Bromo-3 : 4-dimethoxybenz*anti*aldoxime suffered demethylation when exposed to ultra-violet light, giving 5-bromo-4-hydroxy-3-methoxybenz*anti*aldoxime.

A number of derivatives of the *anti*-oximes have been examined, and of these the three *O*-ethers, viz., the methyl ethers of *m*- and *p*-nitrobenz*anti*aldoximes and the benzyl ether of *p*-nitrobenz*anti*aldoxime, were converted into the *syn*-isomeride, although not so completely as the oximes. Of the two nitrogen ethers investigated, the *N*-methyl ether of benzaldoxime is decomposed, yielding benzonitrile, whilst the *N*-methyl ether of *m*-nitrobenzaldoxime undergoes no change. R. B.

Configuration of Stereoisomeric Oximes and the Structure of Oxime-*N*-ethers and *aci*-Nitro Derivatives. K. von Auwers and B. Ottens (*Ber.*, 1924, **57**, [*B*], 446—461).—The spectrochemical behaviour of a series of oximes is found to be closely similar to that of their *O*-alkyl and acyl derivatives. Since the latter substances necessarily contain the group $\colon C\colon N\cdot OR$, it follows that the oximes themselves must have the constitution $\colon C\colon N\cdot OH$. Confirmation of this view is found in the observation that the benzylideneamines, which undoubtedly contain the similar, conjugated group, $\cdot C\colon C\cdot CH\colon N-$, have molecular exaltations which are of the same order of magnitude as those of the oximes. A consideration of the magnitudes of the physical constants of the oximes renders it very improbable that a three-membered ring,  $>C<\overset{N-}{\underset{O}{|}}$, is present, although a direct estimation of the influence of the ring is impossible, since there is no known compound in which its presence has been established definitely. It is, however, scarcely conceivable that such a ring, even when conjugated with a double linking, could produce the observed remarkable increase in index of refraction and dispersive power, particularly since heterocyclic rings containing nitrogen, such as  $\begin{matrix}\cdot C\\ |\\ \cdot C\end{matrix}\!>\!N\cdot$ and  $\begin{matrix}\cdot N\\ |\\ \cdot N\end{matrix}\!>\!C$, are optically indifferent. The "nitrone" formula, $:C:NH:O$, for the oximes is excluded, since their *N*-ethers are characterised by unusually high dispersive power, which could scarcely fall to a small fraction in the oximes themselves if the latter substances yielded the *N*-ethers simply by the replacement of hydrogen by alkyl without any structural change.

Attempts to discriminate between the *cis*- and *trans*-forms of stereoisomeric oximes, on the hypothesis that the former varieties exhibit higher densities and refractive indices but smaller molecular refractions and dispersions than the *trans*-compounds, are described. In the cases of the benzaldoximes and their ethers, it is found that the α-oxime has the *syn*-configuration; this is opposed to the customary view, but is in harmony with the recent observations of Meisenheimer (A., 1922, i, 152) and Beckmann (A., 1923, i, 228). In a number of other instances, the interpretation of the observed results is much more difficult; at present, it is not possible to form a definite opinion as to the value of spectrochemical evidence in this field.

The optical behaviour of the *N*-ethers of oximes is strongly against the existence of a three-membered ring,  $:C<\begin{matrix}N\cdot R\\ |\\ O\end{matrix}$, the presence of which could not explain the observed powerful exaltations; it is consonant with the structure $:C:NR:O$, experimental evidence for which has been adduced by Semper and Lichtenstadt (A., 1918, i, 437) and by Staudinger (A., 1919, i, 584).

The optical properties of the carbamidoximes (cf. Conduché, A., 1908, i, 12, 154), of the *aci*-forms of the nitroparaffins and of tetranitromethane are in agreement with the constitutions, $RR'C:N(:O)\cdot CO\cdot NH_2$, $RR'C:N(:O)\cdot OH$, and $(NO_2)_2C:N(:O)\cdot O\cdot NO_2$, respectively.

The physical constants have been observed partly with homogeneous material, partly with substances dissolved in quinoline which is found to be a very suitable solvent for this purpose. The following data, amongst others, are recorded. Heptaldoxime, $d_4^{99\cdot8}$ 0·8219, $n_{He}^{99\cdot8}$ 1·41514. α-Mesityl oxideoxime, b. p. 84°/11 mm., d_4^{100} 0·876, n_{He}^{100} 1·450. β-Mesityl oxideoxime, b. p. 95°/11 mm., d_4^{100} 0·881, n_{He}^{100} 1·462. α-Mesityl oxideoxime acetate, b. p. 101°/11 mm., d_4^{20} 0·986, n_{He}^{20} 1·474. β-Mesityl oxideoxime acetate, b. p. 107°/14 mm., d_4^{20} 0·990, n_{He}^{20} 1·478. α-Mesityl oxideoxime benzyl ether, b. p. 131°/11 mm., d_4^{20} 0·987, n_{He}^{20} 1·533. α-Benzaldoxime, m. p. 35°, d_4^{20} 1·110, n_{He}^{20} 1·593. α-Benzaldoxime *O*-methyl ether, b. p. 79°/11 mm., d_4^{20} 1·020, n_{He}^{20} 1·548. β-*Benzaldoxime* O-*methyl ether*, b. p. 79°/11 mm., d_4^{20} 1·028, n_{He}^{20} 1·550. α-Benzaldoxime acetate, d_4^{20} 1·107, n_{He}^{20} 1·544.

Heptaldoxime *N*-benzyl ether, $d_4^{99\cdot6}$ 0·9293, $n_{He}^{99\cdot6}$ 1·49714. Furfuraldoxime *N*-methyl ether, $d_4^{99\cdot8}$ 1·1185, $n_{He}^{99\cdot8}$ 1·56351. Furfuraldoxime *N*-benzyl ether, $d_4^{99\cdot7}$ 1·1270, $n_{He}^{99\cdot7}$ 1·59871. β-Benzaldoxime *N*-methyl ether, $d_4^{99\cdot9}$ 1·0528, $n_{He}^{99\cdot9}$ 1·59189. o-*Chlorobenzaldoxime* N-*phenyl ether*, coarse, pale yellow crystals, m. p. 81·5—82·5° (from *o*-chlorobenzaldehyde and phenylhydroxylamine), $d_4^{100\cdot3}$ 1·2008, $n_{He}^{100\cdot3}$ 1·64853. Phenylnitromethane, $d_4^{24\cdot7}$ 1·1540, $n_{He}^{24\cdot7}$ 1·52850. aci-*Phenylnitromethane methyl ether*, from nitromethane, methyl sulphate, and sodium hydroxide, a pale yellow liquid with an odour of bitter almonds, b. p. 117°/15 mm., ca. 83°/1·5 mm., $d_4^{15\cdot0}$ 1·1241, $n_{He}^{15\cdot0}$ 1·58708. Tetranitromethane, $d_4^{16\cdot9}$ 1·6425, $n_{He}^{16\cdot9}$ 1·43976.

Benzylidenemethylamine, $CHPh{:}NMe$, b. p. 185°, d_4^{20} 0·962, n_{He}^{20} 1·553. Benzylidene-ethylamine, b. p. 195°, d_4^{20} 0·937, n_{He}^{20} 1·541. Benzylidene*iso*amylamine, b. p. 245°, d_4^{20} 0·906, n_{He}^{20} 1·519. Benzylideneaniline, b. p. 300°, $d_4^{99\cdot3}$ 1·0041, $n_{He}^{99\cdot3}$ 1·61041. Benzylidene-*o*-toluidine, b. p. 314°, d_4^{20} 1·041, n_{He}^{20} 1·635. H. W.

Reactions of Cinnamalphenylnitrone. D. Bigiavi and M. Marri (*Gazzetta*, 1924, **54**, 99—113).—Among the products obtained by Weitnauer (Dissertation, Basle, 1904) on reducing phenyl*iso*cinnamaldoxime by means of sodium or sodium amalgam and absolute alcohol were two compounds described by this author as (1) liquid secondary base, b. p. 190—190·5°/8 mm., and (2) solid secondary base, m. p. 90—90·5°, and regarded as having the structures, $NHPh{\cdot}CH_2{\cdot}CH_2{\cdot}CH_2Ph$, and $NHPh{\cdot}CH(OH){\cdot}CH_2{\cdot}CH_2Ph$, respectively. The authors show that the solid base, m. p. 90°, is actually hydrocinnamanilide, its formation being the result of migration of the oxygen atom of the phenyl*iso*cinnamaldoxime from the nitrogen to the adjacent carbon atom, followed by hydrogenation of the cinnamanilide thus formed: $O{:}NPh{:}CH{\cdot}CH{:}CHPh \longrightarrow NHPh{\cdot}CO{\cdot}CH{:}CHPh \longrightarrow NHPh{\cdot}CO{\cdot}CH_2{\cdot}CH_2Ph$. Similar transpositions are exhibited by a large number of compounds, including nitrones (cf. Miescher, "Nitrone und Nitrene," Zurich, 1918, 20). By acetic anhydride, cinnamalphenylnitrone is converted quantitatively into the acetyl derivative of cinnamanilide as the result of an intensely exothermic reaction, hydrolysis then yielding the anilide: $O{:}NPh{:}CH{\cdot}CH{:}CHPh \longrightarrow NHPh{\cdot}CO{\cdot}CH{:}CHPh$; catalytic reduction of cinnamanilide by means of hydrogen and platinum black yields hydrocinnamanilide, identical with the product obtained by heating aniline with hydrocinnamic acid.

By catalytic reduction, Cusmano (A., 1922, i, 143) has converted nitrones into hydroxylamines. From cinnamalphenylnitrone this author has obtained, by reduction with hydrogen and platinum black, a compound which is apparently a hydroxylamine. This marked divergence in behaviour must be due to the presence of conjugated double bonds in the molecule of cinnamalphenylnitrone.

By dilute sulphuric acid, cinnamalphenylnitrone is readily converted into the Schiff's base of *p*-aminophenol:

$$O{:}NPh{:}CH{\cdot}CH{:}CHPh \longrightarrow OH{\cdot}C_6H_4{\cdot}N{:}CH{\cdot}CH{:}CHPh$$

(cf. Angeli, Alessandri, and Pegna, A., 1910, i, 552). Analogous reactions produced by dilute sulphuric acid are: $O{:}NH_2Ph \longrightarrow OH{\cdot}C_6H_4{\cdot}NH_2$; $O{:}NPh{:}NPh \longrightarrow OH{\cdot}C_6H_4{\cdot}N{:}NPh$; $O{:}NPhMe_2$

$\longrightarrow$ $OH\cdot C_6H_4\cdot NMe_2$. On other nitrones, the acid exerts a hydrolysing action, the original aldehyde or ketone and aryhydroxylamine being regenerated.

The *acetyl* derivative of cinnamanilide, $C_{17}H_{15}O_2N$, forms acicular crystals, m. p. 138—139°.

Hydrocinnamanilide, $C_{15}H_{15}ON$, crystallises in lustrous, white needles, m. p. 98°, and exhibits the normal molecular weight in acetic acid. It is stable towards alcoholic potassium hydroxide, but is rapidly hydrolysed when heated with dilute sulphuric acid. Sodium and alcohol reduce it to aniline and another base, which is probably Weitnauer's liquid secondary base. With nitrous acid, it appears to yield a nitrosoamine. Its *acetyl* derivative, $C_{17}H_{17}O_2N$, forms minute, refractive crystals, m. p. 45°. T. H. P.

Oxides of the Stereoisomeric Trithiobenzaldehydes. O. HINSBERG (*Ber.*, 1924, **57**, [*B*], 417—419).—A detailed reply to the criticisms of Fromm and Schultis (A., 1923, i, 580) on the author's work (A., 1914, i, 185). Contrary to the views of Fromm and Schultis, α-trithiobenzaldehyde pentoxide (disulphone-sulphoxide) must be regarded as a homogeneous substance. The individuality of δ-trithiobenzaldehyde tetroxide is not, however, established with equal certainty, and it is possible that the product is a difficultly separable mixture of the tri-, tetra-, and pent-oxides, but this is not conclusively proved by the experiments of Fromm and Schultis. Valid evidence against the existence of δ-trithiobenzaldehyde has not been adduced. H. W.

Pinacolin Transformation in the Dehydration of 1 : 2-Dimethyl*cyclo*hexane-1 : 2-diol. S. NAMETKIN and N. DELEKTORSKY (*Ber.*, 1924, **57**, [*B*], 583—587).—1 : 2-Dimethyl*cyclo*hexane-1 : 2-diol, m. p. 92—93°, prepared by hydrating the corresponding oxide at the ordinary temperature with very dilute sulphuric acid, was heated at 150—160° for 3 hours with acidulated water. On cooling, the pinacolin separated as an oil possessing a peppermint-like odour and distilling, after purification by means of its semicarbazone, at 60·5°/20 mm. It was found to be identical with 1-methyl-1-*cyclo*pentyl methyl ketone (Meerwein, A., 1919, i, 162). The pinacolin transformation is therefore accompanied by the change from a six-ring to a five-ring. The reverse change occurs on dehydrating 1-methyl-1-α-hydroxyethyl*cyclo*pentane, the product being 1 : 2-dimethyl-Δ^1-*cyclo*hexene (Meerwein, *loc. cit.*). F. A. M.

Oxidation of Sabinene with Chromyl Chloride. A Correction. G. G. HENDERSON and J. M. ROBERTSON (*J. Chem. Soc.*, 1924, **125**, 765—766).—The supposed 4-*iso*propylidene*cyclo*hexanone obtained by the oxidation of sabinene with chromyl chloride (*Chem. Soc. Trans.*, 1922, **121**, 2717) has now been found to be *p*-tolyl methyl ketone. The alcohol obtained by its reduction is therefore *p*-tolylmethylcarbinol. The formation of this ketone from sabinene is attributed to oxidation of part of the sabinene to cymene, which with chromyl chloride forms the compound $C_{10}H_{14},2CrO_2Cl_2$, from which *p*-tolyl methyl ketone is formed on decomposition with water. R. B.

Change of State of Aggregation and Polymorphism. III. Polymorphism of Benzophenone. K. Schaum and K. Unger (*Z. anorg. Chem.*, 1924, **132**, 90—98; cf. A., 1916, i, 405).—The instability of the metastable form of benzophenone makes the investigation of its pseudo-binary character difficult. On this account, the *p*-halogen and *p*-hydroxy derivatives were examined. These were found to be monotropic trimorphic, but the m. p. of the three forms lie very close together, not more than 0·5° apart. The effect of previous history on the m. p. of benzophenone was examined. No difference could be detected after heating for different periods of time at different temperatures. H. T.

Preparation of 3 : 3′-Dinitrobenzophenone. E. de B. Barnett and M. A. Matthews (*J. Chem. Soc.*, 1924, **125**, 767).—By nitration of benzophenone in sulphuric acid solution with nitric acid (*d* 1·50) at 25—30°, a yield of 50% of theory of crude 3 : 3′-dinitrobenzophenone was obtained, which after one crystallisation from methyl ethyl ketone melted at 155°. R. B.

Valency. I. Estimation of the Strength of the Bond between a Radical and Carbon. A. Schonberg, R. Abelsdorff, H. Kirchrath, W. Malchow, and A. Rosenbach (*Annalen*, 1924, **436**, 205—218).—The reaction between benzophenone and sodamide, first studied by Haller (A., 1908, i, 987), has been applied to substituted aromatic ketones. Benzophenone, in toluene solution, gives as a final product benzamide: $Ph_2CO+NaNH_2 \longrightarrow Ph_2C(NH_2)ONa \longrightarrow C_6H_6+Ph{\cdot}CO{\cdot}NHNa \longrightarrow Ph{\cdot}CO{\cdot}NH_2$. With an unsymmetrical substituted benzophenone, the reaction may proceed in two ways, giving benzene and a substituted benzamide, or a substituted benzene and benzamide. It is shown that Haller's explanation (*loc. cit.*) of the reaction is incorrect; for instance, diphenyl phenyl ketone with sodamide in toluene solution gives diphenyl, which agrees with the above scheme. The yields in this reaction are practically quantitative, so that by determining the proportions of the free acids (obtained by hydrolysis of the amides) formed, it is possible to determine the relative affinity of the various radicals for carbonyl carbon, and comparative numerical values can be assigned to each radical. Taking the affinity of the phenyl radical as the unit, the following values are assigned to substituted phenyl radicals containing the substituent groups indicated:—*m*-chloro-, 0·05—0·32; *m*-bromo-, 0·08—0·38; *p*-chloro-, 0·18—0·51; *p*-bromo-, 0·18—0·65; *p*-methoxy-, 1·12—2·16; and *p*-dimethylamino-, about 1·23. The value for the radicals CPh_3– and $CPh_2(ONa)$– is less than 0·14. If the ketone is not decomposed by sodamide, for example, phenyl triphenylmethyl ketone, hydrolysis with alkali is resorted to, the final products being triphenylacetic acid and benzoic acid, in proportions depending on the relative affinities of the triphenylmethyl and phenyl radicals. The method fails with aliphatic ketones, a sodium compound of the ketone being formed.

p-*Methylmercaptobenzophenone*, colourless prisms, m. p. 79°, was synthesised from benzoyl chloride, methyl phenyl sulphide, and aluminium chloride in carbon disulphide solution; (*phenylhydrazone*, colourless crystals, m. p. 90°). p-*Methylmercaptobenzoic acid*, by the action of sodamide on the ketone in toluene solution, forms prisms, m. p. 192°. 4 : 4′-Dimethylmercaptobenzophenone, from thioanisole and oxalyl chloride in presence of aluminium chloride in ice-cold carbon disulphide solution, forms colourless scales, m. p. 125·5° (anil, yellow prisms, m. p. 135°). A. E. C.

Isomeric *p*′-Methylchalkones [*p*-Tolyl Styryl Ketones]. C. Weygand (*Ber.*, 1924, **57**, [*B*], 413—417).—*p*-Tolyl methyl ketone, condensed with benzaldehyde and sodium ethoxide, yields *p*-methylchalkone (*p*-tolyl styryl ketone), m. p. 590 (cf. Sorge, A., 1902, i, 379); on recrystallising several months later, it was suddenly converted into the isomeric form, m. p. 77°, described by Kostanecki (A., 1896, i, 688), and during the night all the other uncovered preparations were converted into the same modification. All subsequent preparations gave only the 77° form, which on heating to 135° and cooling deposits the form, m. p. 59°; this is at once changed into the 77° modification when touched with a crystal of the latter. Both forms could be crystallised from suitable solvents at first, but once the 77° form had appeared it became nearly impossible to recover the 59° form from solution except by working at low temperatures or in air-tight vessels. Both forms give orange-yellow solutions in concentrated sulphuric acid, the 77° form being deposited on dilution; both yield the same *dibromide* as a white, crystalline powder, m. p. 175—176°, the same *compound* with stannic chloride, m. p. 85° (not sharp), and the same aniline additive *compound*, m. p. 141°. At 21°, 100 g. of benzene dissolve about 55·8 g. of the 77° form, and 166·8 g. of the 59° form. Both forms have normal molecular weights in benzene. F. A. M.

Insecticides. IV. Constitution of Tetrahydropyrethrone. H. Staudinger and L. Ruzicka (*Helv. Chim. Acta*, 1924, **7**, 236—244).—It was shown in a previous paper (p. 523) that reduction of pyrethrolone by the Paal–Skita method gives tetrahydropyrethrolone. When the reduction is pushed to the limit, the hydroxyl group is also reduced, tetrahydropyrethrone being formed. Complete reduction is effected more readily with the acetate or the methyl ether than with pyrethrolone itself. *Tetrahydropyrethrone* is a colourless, mobile liquid with a faint, ethereal odour, b. p. 100—101°/12 mm. Its constitution, determined from its oxidation products, is 3-*methyl*-2-n-*amylcyclopentanone*,

$$\left.\begin{array}{l}\mathrm{CH_2{\cdot}CHMe}\\ \mathrm{CH_2{-}{-}CO}\end{array}\right>\mathrm{CH{\cdot}C_5H_{11}}.$$

The *semicarbazone* varies in melting point from 160° to 194°, according to the manner in which the ketone is prepared. That of m. p. 194°, from the ketone obtained by reduction of pyrethrolone acetate, is the *lævo* form; that having m. p. 160° is the *racemic* form. The p-*nitrophenylhydrazone* (*r*-form) forms yellow needles, m. p. 87°. By oxidation of tetrahydropyrethrone with potassium permanganate, hexoic and lævulic acids were obtained. Their formation is compatible with two possible formulæ, a *cyclo*pentane derivative with the keto group in the ring or a *cyclo*butane derivative with the keto group in the side chain. The oxime of the former should give a lactam by the Beckmann change, whilst the oxime of the latter should give an acid amide. The *oxime* of tetrahydropyrethrone is a colourless oil, b. p. 84—85°/0·1 mm., which, by treatment with concentrated sulphuric acid, is converted into the iso-*oxime*, a viscous oil, b. p. 120°/0·1 mm. The latter is converted by boiling hydrochloric acid into *δ-amino-γ-methyldecoic acid*, which by treatment with nitrous acid is converted into the *lactone* of *δ-hydroxy-γ-methyldecoic acid*. The constitution of tetrahydropyrethrone as 3-methyl-2-*n*-amyl*cyclo*pentanone is therefore established. E. H. R.

Insecticides. V. Synthesis of Tetrahydropyrethrone, the Reduction Product of Pyrethrolone. H. Staudinger and L. Ruzicka (*Helv. Chim. Acta*, 1924, 7, 245—259).—The constitution of tetrahydropyrethrone, which was concluded to be 3-methyl-2-*n*-amyl*cyclo*pentanone (preceding abstract), has been confirmed by synthesis as follows: *Ethyl α-bromoheptoate* (colourless oil, b. p. 106—107°/12 mm.) was condensed with ethyl lævulate, forming the *γ-lactone* of *ethyl hydrogen γ-hydroxy-γ-methylnonane-αδ-dicarboxylate*,  $C_5H_{11}\cdot CH(CO_2Et)\cdot \underbrace{CMe\cdot[CH_2]_2\cdot CO}_{O}$, a colourless, viscous oil, b. p. 130°/0·1 mm. When hydrolysed with 25% potassium hydroxide, the lactone ester is decomposed to a great extent into heptoic and lævulic acids, and only a small yield of *γ-hydroxy-β-methylnonane-αδ-dicarboxylic acid lactone* is obtained, white crystals, m. p. 86—87°. When the disodium salt of the free adipic acid is heated, it loses water and carbon dioxide, forming *γ-methyl-Δ^{γ}-decenoic acid*, $C_5H_{11}\cdot CH\colon CMe\cdot[CH_2]_2\cdot CO_2H$, a viscous oil of peculiar odour, b. p. 160—163°/15 mm. (p-*toluidide*, m. p. 44—45°; *α-naphthylamide*, m. p. 63—64°), which is reduced by the Paal–Skita method to *γ-methyldecoic acid*, a colourless oil, b. p. 150—152°/12 mm. (p-*toluidide*, m. p. 34—36°; *α-naphthylamide*, m. p. 61—62°).

When the condensation of ethyl α-bromoheptoate and ethyl lævulate with zinc was continued for a prolonged period at 150°, one of the reaction products was a butylene derivative, *ethyl hydrogen γ-methyl-Δ^{γ}-nonylene-αδ-dicarboxylate* (*δ-carbethoxy-γ-methyl-Δ^{γ}-decenoic acid*), $C_5H_{11}\cdot C(CO_2Et)\colon CMe\cdot[CH_2]_2\cdot CO_2H$, a colourless oil, b. p. 150°/0·4 mm., which could not be reduced with hydrogen (Paal–Skita) or sodium amalgam; the *ethyl* ester has b. p 170—180°/15 mm. When the ester was boiled with sodium and xylene, and the sodium compound of the resulting methylamyl*cyclo*pentanonecarboxylate boiled with 20% sulphuric acid, *3-methyl-2-amyl-Δ^2-*cyclo*pentenone* was obtained, a colourless oil, b. p. 115—117°/12 mm. (*semicarbazone*, m. p. 175—176°; p-*nitrophenylhydrazone*, m. p. 118—119°). The unsaturated ketone could only be reduced by passing its vapour with hydrogen over nickel at 240—250°. The resulting 3-methyl-2-amyl*cyclo*pentanone was identical with tetrahydropyrethrone.

The following compounds were obtained in unsuccessful attempts to effect the synthesis: 3-*Methyl*-5-n-*amyl*cyclo*pentanone*, colourless liquid, b. p. 107—109°/14 mm. (*semicarbazone*, m. p. 147—148°; p-*nitrophenylhydrazone*, m. p. 134—135°), by condensing ethyl β-methyladipate to a *cyclo*pentanonecarboxylic acid by Dieckmann's method (A., 1900, i, 297) and heating the sodium salt of this acid with amyl bromide. *Ethyl* β-*methylbutane*-ααδ-*tricarboxylate*, colourless oil, b. p. 135°/0·4 mm. (from ethyl malonate and ethyl γ-bromovalerate, in presence of sodium), reacted slowly with *n*-amyl bromide in presence of alcoholic sodium ethoxide, giving the same methylamyl*cyclo*pentanone as above and by-products.

E. H. R.

Insecticides. III. Constitution of Pyrethrolone. H. STAUDINGER and L. RUZICKA (*Helv. Chim. Acta*, 1924, 7, 212—235).—The alcoholic constituent of the active substances in insect powder, pyrethrolone, $C_{11}H_{16}O_2$, is obtained from the semicarbazone already described by careful cold hydrolysis with potassium hydrogen sulphate in presence of benzene and water. It forms a viscous oil, b. p. 111—112°/0·05 mm., $[\alpha]_D^{20}$ −6·2° (approx.). Pyrethrolone probably has the constitution 1-*methyl*-2-*pentadienyl*-cyclo*pentane*-4-*ol*-3-*one*,

$$\begin{array}{l}CH_2\cdot CHMe\\ \quad|\\ OH\cdot CH——CO\end{array}\!\!>CH\cdot CH_2\cdot CH{:}C{:}CHMe$$

; it forms a p-*nitrophenylosazone*, a brown, microcrystalline powder, decomposing above 350°; and an *acetate*, $C_{13}H_{18}O_3$, a colourless, mobile oil, b. p. 104—105°/0·5 mm., $[\alpha]_D^{15}$ −23·79°, which forms a crystalline *semicarbazone*, m. p. 143—145°. When treated with alkali it undergoes autoxidation, forming *dehydropyrethrolone*, a mobile oil, b. p. 82°/0·05 mm., which gives a *semicarbazone*, m. p. 251°, and a second oxidation product, a viscous oil, probably a polymerised form of the first; both are weakly acidic. By methylation with methyl alcohol and concentrated sulphuric acid, pyrethrolone semicarbazone forms a *methyl* ether, m. p. 183°, which, by removal of the semicarbazone group gives the *methyl* ether of pyrethrolone, a mobile oil, b. p. 82—83°/0·25 mm. Pyrethrolone itself can be methylated with methyl sulphate to give the same product, but with methyl alcohol and sulphuric acid it gives a different product forming a *semicarbazone*, m. p. 207°. The *ethyl* ether of pyrethrolone is a colourless liquid, b. p. 102—103° in the highest vacuum; *semicarbazone*, m. p. 179—180°.

When pyrethrolone is reduced by the Paal–Skita method, it takes up 2 mols. of hydrogen, forming *tetrahydropyrethrolone*, which is shown (p. 521) to be 1-*methyl*-2-n-*amyl*cyclo*pentane*-4-*ol*-3-*one*; it is a viscous oil, b. p. 160—162°/10 mm., 108—110°/0·1 mm.; $[\alpha]_D^{20}$ −11·32°, with strong reducing properties. When esterified with chrysanthemumyl chloride, it gives a product having no insecticidal properties. Tetrahydropyrethrolone forms a p-*nitrophenylosazone*, decomposing above 350°; a *semicarbazone*, m. p. 189—190° (decomp.); an *acetate*, a mobile oil, b. p. 110°/0·16 mm., and a *methyl* ether, a colourless, mobile oil, b. p. 128°/12 mm., obtained by reduction of pyrethrolone methyl ether. By oxidation with potassium permanganate, tetrahydropyrethrolone gives hexoic acid. Decomposition of the mono-ozonide of pyrethrolone gives acetaldehyde and acetic acid, showing the presence of an ethylidene group. Malonic acid was also obtained by further oxidising the products obtained from the ozonide with hydrogen peroxide. By ozonisation of pyrethrolone acetate, an acid was obtained which appeared to be an *acetoxymethyl*cyclo*pentenone-homocarboxylic acid*,  $\left.\begin{array}{l}\mathrm{CH{-}CHMe}\\ \|\\ \mathrm{C(OAc)\cdot CO}\end{array}\right>\mathrm{CH\cdot CH_2\cdot CO_2H}$; m. p. 136—138°. The above observations, together with the fact that pyrethrolone only absorbs 1 mol. of bromine with ease, support the view that the side chain contains the allene grouping, although this grouping has not previously been found in a natural product. E. H. R.

Hydroxyhydrindone and Chromanone. F. Mayer and L. van Zütphen (*Ber.*, 1924, **57**, [*B*], 618).—A correction. In a previous paper (this vol., i, 410) the authors claimed to have synthesised chromanone by the action of aluminium chloride on *o*-hydroxyphenyl β-chloroethyl ketone. The product is now admitted to be 7-hydroxyhydrindone, b. p. 128°/13 mm. The benzylidene compound is coloured yellow by sodium hydroxide solution, but is not dissolved even on boiling. (Cf. Krollpfeiffer and Schultze, following abstract.) F. A. M.

Formation of Hydroxyhydrindones from Phenyl Esters of β-Halogenpropionic Acids by Heating with Aluminium Chloride. F. Krollpfeiffer and H. Schultze (*Ber.*, 1924, **57**, [*B*], 600—601; cf. this vol., i, 411).—p-*Tolyl* β-*bromopropionate* is obtained in quantitative yield by heating *p*-cresol with β-propionyl chloride and is a colourless oil, b. p. 162°/14 mm. When it is heated with twice its weight of aluminium chloride at 100—120°, and the product decomposed with iced hydrochloric acid, 80% of the theoretical yield of 1-*hydroxy*-4-*tolyl* β-*bromoethyl ketone* is obtained, forming small, colourless plates, m. p. 72—73°. At 160—170° the product is 4-methyl-7-hydroxyhydrindone, m. p. 110—111°, the yield being 60% of theory. This provides strong evidence that the "γ-chromanone" obtained by Mayer and van Zütphen (this vol., i, 410) is really 7-hydroxyhydrindone. (Cf. Mayer and Zütphen, preceding abstract.) F. A. M.

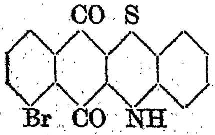
Synthesis of *m*-Dimethoxyphenyl Ethyl and Methyl Ketones. F. Mauthner (*J. pr. Chem.*, 1924, [ii], **107**, 103—108).—To obtain better yields of 3 : 5-dimethoxyphenyl ethyl ketone than were obtained from 3 : 5-dimethoxybenzoyl chloride and zinc ethyl iodide (A., 1922, i, 457), methyl 3 : 5-dimethoxybenzoate was condensed with ethyl acetate by the Claisen method and the *ethyl* 3 : 5-*dimethoxybenzoylacetate*, a pale yellow oil (*pyrazolone* derivative with phenylhydrazine, m. p. 153—154°), was converted by treatment with methyl iodide and sodium ethoxide, followed by hydrolysis with 25% sulphuric acid, into 3 : 5-dimethoxyphenyl ethyl ketone, colourless needles, m. p. 34—35° (*semicarbazone*, colourless needles, m. p. 130—131°). Hydrolysis of ethyl 3 : 5-dimethoxybenzoylacetate with 25% sulphuric acid yields 3 : 5-*dimethoxyphenyl methyl ketone*, colourless needles, m. p. 42—43°, b. p. 151—152°/10 mm. (p-*nitrophenylhydrazone*, reddish-yellow needles, m. p. 157—158°; *semicarbazone*, colourless needles, m. p. 186—187°). Condensation of 3 : 5-dimethoxybenzaldehyde and sodium propionate by the Perkin reaction gives 3 : 5-*dimethoxy-α-methylcinnamic acid*, colourless needles, m. p. 153—154°, but attempts to convert this into 3 : 5-dimethoxypropenylbenzene through loss of carbon dioxide failed. 3 : 5-*Dimethoxyphenylethylcarbinol*, b. p. 170—171°/12 mm. (*phenylurethane*, colourless plates, m. p. 86—87°), was obtained by the Grignard reaction from 3 : 5-dimethoxybenzaldehyde and ethyl iodide; with excess of Grignard reagent 3 : 5-*dimethoxypropenylbenzene* was formed but rapidly polymerised. R. B.

Quinones of Linear Ring Systems with Reactive Halogen in the Non-quinonoid Nucleus. K. Fries and E. Köhler (*Ber.*, 1924, 57, [*B*], 496—510).—A continuation of previous work (Fries and Kerkow, A., 1922, i, 577). 5-Bromoacetnaphthalide can be prepared by the reduction of 5-bromo-1-nitronaphthalene with iron filings and acetic acid or with zinc dust and ammonium chloride and subsequent acetylation of the product or, more economically, by means of iron powder and glacial acetic acid and subsequent treatment of the solution with acetic anhydride. It is converted by a mixture of glacial acetic acid and nitric acid (*d* 1·48) at —2° into a mixture of 5-bromo-2-nitroacetonaphthalide and 5-bromo-4-nitroacetonaphthalide (m. p. 225°), which can be only incompletely separated by fractional crystallisation. Treatment of the mixture with aqueous-alcoholic sodium hydroxide solution leads to the ready isolation of 5-*bromo*-4-*nitro*-α-*naphthylamine*, reddish-brown needles or prismatic crystals, m. p. 192° (*monoacetate*, pale yellow, lustrous needles, m. p. 225°; *diacetate*, pale brown leaflets, m. p. 170°), and 5-*bromo*-2-*nitroacetonaphthalide*, m. p. 240°. 5-Bromo-4-nitro-α-naphthylamine is reduced by stannous chloride and hydrochloric acid in glacial acetic acid solution to 5-*bromo*-1 : 4-*naphthylenediamine*, slender, pale green needles, m. p. 132° (*dihydrochloride*, slender, colourless needles; *diacetyl* compound, colourless needles, m. p. 257°). 5-*Bromo*-1 : 4-*naphthaquinone*, golden-yellow prisms, m. p. 160°, and 5-*bromo*-2-*anilino*-1 : 4-*naphthaquinone*, red, prismatic leaflets, m. p. 219°, are described. The diamine hydrochloride (or the stannic double salt) is transformed by exhaustive chlorination in the presence of glacial acetic and concentrated hydrochloric acids into 2 : 2 : 3 : 3-*tetrachloro*-5-*bromo*-1 : 4-*diketo*-1 : 2 : 3 : 4-*tetrahydronaphthalene*,  $C_6H_3Br<\begin{matrix}CO\cdot CCl_2\\ | \\ CO\cdot CCl_2\end{matrix}$, needles or monoclinic crystals, m. p. 120°, which is reduced by stannous chloride to 2 : 3-*dichloro*-5-*bromo*-1 : 4-*dihydroxynaphthalene*, colourless needles, m. p. 196° (*acetate*, needles, m. p. 154°). The latter substance is oxidised by ferric chloride to 2 : 3-*dichloro*-5-*bromo*-1 : 4-*naphthaquinone*, pale yellow, prismatic crystals, m. p. 180°, which, with aniline, gives 3-*chloro*-5-*bromo*-2-*anilino*-1 : 4-*naphtha*-

quinone, dark red needles, m. p. 239° (the assumption that the chlorine atom in position 2 suffers replacement is arbitrary).

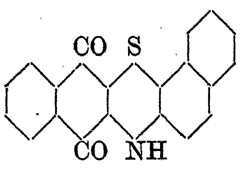
[With G. SCHÜRMANN.]—A similar sequence of changes starting from 8-chloro-4-nitro-α-acetnaphthalide (which is the main product of the nitration of 8-chloro-α-acetnaphthalide) leads to the production of 5-chloro-1 : 4-naphthaquinone and its derivatives. The following compounds are described: 8-*Chloro*-4-*nitro*-α-*naphthylamine*, brownish-red, lustrous plates, m. p. 203° (*acetyl* derivative, needles, m. p. 167°); 5-*chloro*-1 : 4-*naphthylenediamine*, slender, pale yellow needles, m. p. about 116° (decomp.) (*diacetyl* derivative, slender, colourless needles, m. p. 269°); 5-*chloro*-1 : 4-*naphthaquinone*, yellow needles, m. p. 163°; 5-*chloro*-2-*anilino*-1 : 4-*naphthaquinone*, red needles with a bronzy lustre, m. p. 219°; 2 : 2 : 3 : 3 : 5-*pentachloro*-1 : 4-*dihydroxy*-1 : 2 : 3 : 4-*tetrahydronaphthalene*, colourless leaflets, m. p. (indefinite) 82°; 2 : 3 : 5-*trichloro*-1 : 4-*dihydroxynaphthalene*, colourless needles, m. p. 204° (*acetate*, needles, m. p. 162°); 2 : 3 : 5-*trichloro*-1 : 4-*naphthaquinone*, coarse yellow needles, m. p. 156°; 3 : 5-*dichloro*-2-*anilino*-1 : 4-*naphthaquinone*, dark red needles, m. p. 225°; 3-*chloro*-2 : 5-*dianilino*-1 : 4-*naphthaquinone*, needles, m. p. 221°.

5-*Bromo*-2-*nitro*-α-*naphthylamine*, orange-red needles, m. p. 223°, is obtained by hydrolysing the corresponding monoacetyl derivative (see above) with sulphuric acid (*diacetyl* derivative, m. p. 133°). The acetyl compound is converted by boiling, 2*N*-sodium hydroxide solution into 5-*bromo*-2-*nitro*-α-*naphthol*, golden-yellow leaflets, m. p. 142°. 5-*Bromo*-1 : 2-*naphthylenediamine*, colourless plates or slender needles, m. p. 122°, is obtained by reduction of the nitro-amine with tin and hydrochloric acid; the corresponding *diacetyl* derivative, prismatic crystals, m. p. 287°, is transformed by boiling alcoholic sodium hydroxide solution into 6-bromo-2-methyl-αβ-naphthiminazole, colourless, slender needles, m. p. 242°, which is also obtained by the reduction of 5-bromo-2-nitro-α-naphthylamine with stannous chloride in glacial acetic acid solution. The diamine condenses with benzil in alcoholic solution to form the *quinoxaline* derivative, $C_{24}H_{15}N_2Br$, pale yellow needles, m. p. 214°. 3 : 5-*Dichloro*-5-*bromo*-1 : 2-*diketo*-1 : 2 : 3 : 4-*tetrahydronaphthalene* (obtained by chlorination of the diamine), apparently monoclinic crystals, m. p. 93°, 3-*chloro*-5-*bromo*-1 : 2-*dihydroxynaphthalene*, colourless needles, m. p. 176° (*diacetyl* derivative, coarse crystals, m. p. 147°), and 3-*chloro*-5-*bromo*-1 : 2-*naphthaquinone*, small, red plates, m. p. 177°, are described.



3-*Chloro*-5-*bromo*-2-*anilino*-1 : 4-*naphthaquinone*, dark red needles, m. p. 239°, is converted by treatment with sodium sulphide and oxidation of the product by air into 7-*bromo*-ββ-*naphthaphenthiazine*-6 : 11-*quinone* (annexed formula), bluish-green, prismatic crystals, m. p. 325°; the corresponding *sulphoxide*, brownish-red, coarse crystals, m. p. 270°, and the *sulphone*, orange-red, lustrous leaflets, m. p. above 360°, are described. Boiling acetic anhydride and zinc dust convert the quinone into the *triacetyl* derivative of 7-*bromo*-6 : 11-*dihydroxy*-

ββ-*naphthaphenthiazine*, lustrous leaflets, m. p. 299°. 7-*Anilino-ββ-naphthaphenthiazine*-6 : 11-*quinone* crystallises in slender, dark violet needles, m. p. 265°; it gives a yellow vat with hyposulphite. 7-p-*Anisidino*-ββ-*naphthaphenthiazine*-6 : 11-*quinone* forms dark violet crystals, m. p. 230°.



3-*Chloro*-2-β-*naphthylamino*-1 : 4-*naphthaquinone*, m. p. 194°, prepared from 2 : 3-dichloro-1 : 4-naphthaquinone and β-naphthylamine, is transformed in the usual manner into 1 : 2-*benzo*-ββ-*naphthaphenthiazine*-6 : 11-*quinone* (annexed formula), dark, greenish-blue, prismatic crystals, m. p. 300°; the corresponding sulphone crystallises in orange-red leaflets, m. p. above 400°. Zinc dust and boiling acetic anhydride transform the quinone into the *triacetyl* derivative of 6 : 11-*dihydroxy*-1 : 2-*benzo*-ββ-*naphthaphenthiazine*, colourless crystals, m. p. 217°. H. W.

Reduction Products of the Hydroxyanthraquinones. V. F. L. GOODALL and A. G. PERKIN (*J. Chem. Soc.*, 1924, **125**, 470—476).—Hydroxyanthranols can be readily prepared in excellent yield by digesting hydroxyanthraquinones with a boiling 20% solution of stannous chloride in 33% hydrochloric acid. The method is serviceable only in those cases in which anthranol formation has been effected by other methods. With purpurin and purpuroxanthin, reduction is incomplete, whilst quinizarin yields quantitatively deep orange-red crystals of 1 : 4 : 9-trihydroxyanthrone, m. p. 152—154° (A., 1920, i, 745).

The following anthranols have been obtained by this method: 1- and 3-hydroxy-, 3 : 6-, 3 : 7-, and 4 : 8-dihydroxy-anthranols, anthrapurpurin anthranol, and anthragallol anthranol. Deoxyalizarin (3 : 4-dihydroxyanthranol), when acetylated and oxidised with ferric chloride, yields 3 : 4 : 5′ : 6′-*tetrahydroxydianthrone*, small, yellow needles, m. p. 268—270° (decomp.); *hexa-acetyl* derivative, $C_{40}H_{30}O_{12}$, colourless needles, m. p. 236—238°. With alcoholic sulphuric acid, it gives *dihydroxy*-3 : 6′-*diethoxydianthrone*, $C_{32}H_{22}O_6$, small plates, m. p. 271—274°, which on careful oxidation with chromic acid yields alizarin β-ethyl ether, orange needles, m. p. 188—189°. *Tetra-acetyldiethoxydianthranol* has m. p. 248—250°. By treatment with methyl sulphate and alkali the dihydroxydiethoxydianthrone is converted into 3 : 4 : 5′ : 6′-*tetramethoxydianthrone*, colourless needles, m. p. 255—256°. Attempts to convert the tetrahydroxydianthrone into the corresponding helianthrone were unsuccessful. Both deoxyalizarin and tetrahydroxydianthrone are mordant dyes. With bromine in carbon disulphide solution, deoxyalizarin dimethyl ether is converted into 10-bromo-3 : 4-dimethoxyanthranol, from which by the action of dimethylamine or of alcoholic potassium hydroxide only alizarin dimethyl ether is obtained. Acetyldeoxyalizarin, on treatment with nitric acid in alcohol or acetic acid, yields 10-*nitro*-3 : 4-*dihydroxyanthranol diacetate*, $C_{18}H_{13}O_7N$, colourless needles, m. p. 156° (decomp.). The violet colour observed when nitric acid is added to a solution of deoxyalizarin in sulphuric acid is due to the production of nitrodihydroxyanthrone. R. B.

Derivatives of β-Methylanthraquinone. IV. Nitro Derivatives of β-Methylanthraquinone and some of their Transformation Products. R. Eder, C. Widmer, and R. Bütler (*Helv. Chim. Acta*, 1924, 7, 341—357).—The nitro-β-methylanthraquinone prepared by Römer and Link by nitration of β-methylanthraquinone (A., 1883, 1138) has been supposed to be 1-nitro-3-methylanthraquinone, on the ground that the hydroxymethylanthraquinone prepared from it, m. p. 177—178°, is identical with the 1-hydroxy-3-methylanthraquinone prepared synthetically by Bentley, Gardner, and Weizmann (T., 1907, **91**, 1626). Repetition of this work shows that the hydroxy compound from nitro-β-methylanthraquinone really has m. p. 181—182° and is identical with synthetic 1-hydroxy-2-methylanthraquinone. The nitro compound is therefore 1-nitro-2-methylanthraquinone. It is converted into α-aminoanthraquinone through the 1-aminoanthraquinone-2-carboxylic acid by boiling the latter with potassium stannite solution. The nitro compound is best prepared by Römer and Link's method; at higher temperatures, red by-products are formed.

Dinitration of β-methylanthraquinone or nitration of 1-nitro-2-methylanthraquinone gives a mixture of two isomerides, the 1 : 5- and 1 : 8-dinitro compounds. 1 : 5-*Dinitro-2-methylanthraquinone* forms yellow needles, m. p. 329—331°, subliming with partial decomposition in white needles; it is soluble in 50 parts of boiling pyridine, 450 of boiling acetic acid, very sparingly soluble in other solvents. By oxidation with chromic acid in boiling nitric acid solution it gives 1 : 5-*dinitroanthraquinone-2-carboxylic acid*, needles, m. p. 337—339°. By distillation of the *silver* salt (a red powder), 1 : 5-dinitroanthraquinone is obtained, m. p. above 350°, giving by reduction 1 : 5-diaminoanthraquinone, m. p. 309—310°, not 319° as given by Noelting and Wortmann (A., 1906, i, 291). Conversion of this into anthrarufin proved its constitution. In a similar manner, the constitution of 1 : 8-*dinitro-2-methylanthraquinone*, m. p. 293—295°, was established. It forms white to pale yellow needles, sparingly soluble in organic solvents, but more soluble than the 1 : 5-isomeride. Attempts to obtain higher nitrated derivatives of β-methylanthraquinone were unsuccessful. (Cf. Schaarschmidt and Stahlschmidt, A., 1913, i, 95.) E. H. R.

Neorobin. P. Masucci and G. A. Slothower (*J. Amer. Pharm. Assoc.*, 1923, **12**, 335—338).—"Neorobin," which is prepared by reduction of chrysarobin with tin and acetic acid, is neither a compound of tin nor an acetate. It is at least 50% more active as a reducing agent than chrysarobin, and can be determined by addition of ammoniacal silver nitrate to its solution in acetone, followed by determination of the reduced silver in the usual way.

Chemical Abstracts.

1 : 2 : 8-Trimethoxy-6-methylanthraquinone and 1 : 2 : 8-Trimethoxy-7-methylanthraquinone. J. L. Simonsen (*J. Chem. Soc.*, 1924, **125**, 721—726; cf. *ibid.*, 1921, **119**, 1339).—The condensation of hemipinic anhydride with *m*-cresol using aluminium chloride and boric acid as condensing agents yields mainly 2′-*hydroxy*-3 : 4-*dimethoxy*-4′-*methyl*-2-*benzoylbenzoic acid*, glistening needles, m. p. 229—230°, which on methylation with methyl sulphate gives 2′ : 3 : 4-*trimethoxy*-4′-*methyl*-2-*benzoylbenzoic acid*, glistening prisms, m. p. 198—199°, a small quantity of a *phthalein*, $C_{24}H_{22}O_6$, m. p. 285—287°, being obtained as a by-product in the condensation. Concentrated sulphuric acid at 150° converts the 2′-hydroxy-3 : 4-dimethoxy-4′-methyl-2-benzoylbenzoic acid into the corresponding anthraquinone, but in poor yield, and from the crude hydroxyanthraquinone 1 : 2 : 8-*trimethoxy*-6-*methylanthraquinone*, fine yellow needles, m. p. 164—165°, was obtained by methylation. With *o*-cresol the condensation gave mainly 2′-hydroxy-3 : 4-dimethoxy-3′-methyl-2-benzoylbenzoic acid, bevelled prisms, m. p. 250—251°, accompanied by considerable quantities of a *phthalein*, $C_{24}H_{22}O_6$, m. p. 237—238°, when a large excess of *o*-cresol was used. Methylation converted the benzoylbenzoic acid derivative into 2′ : 3 : 4-*trimethoxy*-3′-*methyl*-2-*benzoylbenzoic acid*, hexagonal prisms, m. p. 199° (*methyl* ester, prisms, m. p. 153—155°), whilst heating with sulphuric acid gave an almost quantitative yield of the crude hydroxyanthraquinone, which was methylated with difficulty to 1 : 2 : 8-*trimethoxy*-7-*methylanthraquinone*, yellow needles, m. p. 209—210°. R. B.

Phenanthrene Series. XXXV. Transformations of Chlorophenanthrenes. J. Schmidt and E. Äckerle (*Ber.*, 1924, **57**, [*B*], 363—369).—An extension of the work of Schmidt and Spoun (A., 1922, i, 665). The preparation of 9 : 9- and 10 : 10-dichloro-2-nitrophenanthrones from 2-nitrophenanthraquinone and phosphorus pentachloride in the presence of benzene is described in detail (the position of the chlorine atoms in these compounds is assigned arbitrarily). 9 : 9-Dichloro-2-nitrophenanthrone is reduced by hydroxylamine hydrochloride or phenylhydrazine to 9-*chloro*-2-*nitro*-10-*hydroxyphenanthrene*, yellow needles, m. p. 223° (*acetate*, m. p. 228°; *benzoate*, m. p. 220°). 10 : 10-Dichloro-2-nitrophenanthrone is converted similarly by hydroxylamine hydrochloride into 10-*chloro*-2-*nitro*-9-*hydroxyphenanthrene*, small, yellow crystals, m. p. 193°. It appears therefore that the halogen atoms of the chloro-2-nitrophenanthrones are retained with unexpected firmness; this view is confirmed by the observation that the α-compound is stable towards molecular silver in the presence of boiling benzene.

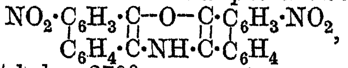
4-Nitrophenanthraquinone is converted by phosphorus pentachloride in the presence of benzene into a mixture of 9 : 9-*dichloro*-4-*nitrophenanthrone* (α-compound), pale yellow crystals, m. p. 203°, and 10 : 10-*dichloro*-4-*nitrophenanthrone* (β-compound), m. p. 137°. The former substance is transformed by hydroxylamine hydrochloride or phenylhydrazine into 9-*chloro*-4-*nitro*-10-*hydroxyphenanthrene*, m. p. 203° (*acetate*, pale yellow powder, m. p. 223°; *benzoate*, small, colourless crystals, m. p. 196°). 10-*Chloro*-4-*nitro*-9-*hydroxyphenanthrene* has m. p. 153—154° (*benzoate*, m. p. 188—189°).

4-Nitrophenanthraquinone is converted by phosphorus pentachloride under pressure at 120° into 9 : 9 : 10 : 10-*tetrachloro-4-nitrodihydrophenanthrene*, slender, brownish-yellow needles, m. p. 164—165°, which is transformed by phenylhydrazine or molecular silver into 9 : 10-*dichloro-4-nitrophenanthrene*, m. p. 136—137°; the chlorine atoms are retained with extraordinary firmness in these compounds, particularly in the latter.

Di-9-chloro-2-nitro-10-phenanthryl ether,

$\left(C_6H_4{<}\begin{matrix}C_6H_3(NO_2)\\ \text{———}CCl\end{matrix}{>}C\right)_2O$,

a brown substance which does not melt below 370°, is obtained as a by-product of the action of acetic anhydride on 9-chloro-2-nitro-10-hydroxyphenanthrene. The latter substance is converted by alcoholic ammonia at 160° into 2-*nitrophenanthroxazine*,



$$\begin{matrix}NO_2\cdot C_6H_3\cdot C\text{—}O\text{—}C\cdot C_6H_3\cdot NO_2\\ C_6H_4\cdot C\cdot NH\cdot C\cdot C_6H_4\end{matrix},$$

which does not melt below 370°. H. W.

Enolisation of Camphor. M. Bredt-Savelsberg, C. A. Heinemann, P. Catharinus, and H. Eibel (*J. pr. Chem.*, 1924, [ii], **107**, 65—86).—The method of Tschugaev and Zerevitinov (A., 1907, ii, 509) for the determination of hydroxyl groups has been applied to a study of the enolisation of camphor. When camphor, which in ether, benzene, or alcohol solution is known to possess the ketonic structure, is brought into contact with a Grignard reagent, enolisation takes place and its extent is determined from the hydrocarbon produced corresponding with the alkyl or aryl group in the Grignard reagent used. Thus magnesium methyl halides give methane, magnesium phenyl bromide gives benzene. The extent of the enolisation depends on a number of factors. (1) The alkyl or aryl group in the Grignard reagent. Equimolecular quantities of camphor and Grignard reagent in ether solution show 29% enolisation with magnesium methyl iodide, 14% with magnesium ethyl iodide, and 25% with magnesium α-naphthyl bromide. In the second case, ethylene is produced as well as ethane, in the ratio of about 3 : 10 at 30°. In amyl ether solution, magnesium phenyl bromide shows 21% enolisation (in ethyl ether solution it was very difficult to determine the benzene formed). (2) The halogen present in the Grignard reagent. With the magnesium methyl halides the enolisation of the camphor increases with the electronegative character of the halogen, from about 14·8% in the case of the iodide to 28·2% with the chloride. (3) The proportions of Grignard reagent and camphor. Excess of Grignard reagent favours enolisation of the camphor. With the proportions ½, 1, 2, and 3 mols. of camphor to 1 mol. of Grignard reagent the enolisation figures were 32·6, 14·9, 16·3, and 16·9%, respectively. (4) The time of reaction. Equilibrium is only reached after a prolonged period. With magnesium methyl iodide, periods of ½, 5, 10, 25, and 40 hours showed enolisation of 13·0, 14·1, 14·9, 30·4, and 44·7%, respectively. (5) The character of the solvent. In amyl ether solution, magnesium methyl iodide enolises camphor to the extent of about 3·6%, against 44·7% in ethyl ether. In a solvent free from oxygen (benzene) the enolisation is 32·5%. (6) The temperature of reaction. With magnesium methyl iodide the enolisation figures in 10 hours were found to be 6·85% at 0° and 14·9% at 20°. The enolisation of camphor by Grignard reagents explains the low yields of tertiary borneols which have been obtained by the Grignard method, as only the keto-form yields a complex from which tertiary borneols are formed. R. B.

Pyroelectricity of Two Derivatives of Camphor. M. R. LUCAS.—(See ii, 224.)

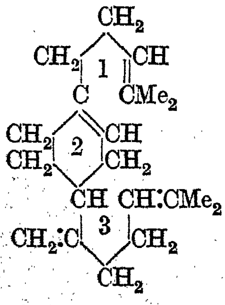
Oxidation of *allo*-Ocimene, Ocimene, and Myrcene. C. J. ENKLAAR (*Chem. Weekblad*, 1924, **21**, 101—102; cf. A., 1906, i, 377).—A sample of *allo*-ocimene (b. p. 98—102°/32 mm.) on treatment with permanganate in dry acetone at 0° was only partly oxidised. The only oxidation product obtained was a neutral substance, allo-*ocimene oxide*, probably $C_{10}H_{16}O$, b. p. 105°/13 mm., d^{20} 0·909, which is neither aldehyde, ketone, nor glycol. By the action of permanganate on ocimene in acetone solution at 56°, an acid (lead salt, crystallising in rhombs) was obtained; this lead salt is suitable for the identification of the terpene. Myrcene under these conditions yields an acid of which the lead salt crystallises in fine needles, readily distinguishable from the ocimene lead salt. By exhaustive treatment of ocimene with permanganate, a mixture was obtained in which only oxalic acid could be identified. S. I. L.

Catalytic Action. IV. A Function of Reduced Copper. S. KOMATSU (*Mem. Coll. Sci. Kyōtō*, 1924, **7**, 85—91).—When menthol is passed over reduced copper at 320°, besides the expected menthone, some menthene is formed. The copper therefore acts, like thoria, as a dehydrating agent. In the same way, ethyl alcohol yields acetaldehyde and ethylene, and *iso*propyl alcohol (at 300°) gives acetone and propylene. *cyclo*Hexanol is likewise dehydrogenated and dehydrated; *cyclo*hexene, *cyclo*hexanone, di*cyclo*hexyl ether, and water are produced in quantities agreeing with the author's explanation of the reaction, based on the supposition that dehydration takes place in three directions simultaneously.
W. A. S.

Higher Terpene Compounds. XX. Sesquiterpenes and Sesquiterpene Alcohols of Camphor Oil. L. RUZICKA and M. STOLL (*Helv. Chim. Acta*, 1924, **7**, 260—270).—So-called heavy camphor oil, b. p. 110—140°/12 mm., contains, besides cadinene and bisabolene, a monocyclic *hydrocarbon*, $C_{15}H_{24}$, which was not more exactly characterised, but forms a very stable *dihydrochloride*, an oil, b. p. 125°/0·3 mm., and a bicyclic *hydrocarbon*, $C_{15}H_{24}$, a colourless oil, b. p. 128—135°/12 mm., which must be of the cadinene type since, when dehydrogenated by boiling with sulphur, it gives cadaline. The sesquiterpene alcohol fraction of camphor oil, b. p. 150—160°/12 mm., gives cadaline when dehydrogenated with sulphur. Purification of this alcohol fraction through the benzoate gives 15% of an alcohol, b. p. 155—160°/12 mm., which agrees in properties with Semmler and Rosenberg's sesquicamphenol (A., 1913, i, 378). When this purified alcohol was dehydrogenated with sulphur and the product fractionated, the fraction of b. p. 140—145°/12 mm. contained eudaline whilst that of b. p. 150—165°/12 mm. contained cadaline. Camphor oil therefore contains compounds of both cadinene and eudesmol types, and is unique in this respect. The alcohol fraction was separated by means of phthalic anhydride into primary, secondary, and tertiary constituents. The *primary* sesquicamphenol has b. p. 156—158°/12 mm., $[\alpha]_D$ +2·2°, d_4^{18} 0·9568, n_D^{18} 1·5045. It is reduced by hydrogen in presence of platinum black to a *dihydrosesquicamphenol*, $C_{15}H_{28}O$, a colourless, viscous oil, b. p. 152—153°/12 mm., d_4^{22} 0·9150, n_D^{22} 1·4755. From the purified sesquiterpene alcohols a *secondary* sesquicamphenol, b. p. 160—162°/12 mm., $[\alpha]_D$ −5·2°, d_4^{20} 0·9720, n_D^{20} 1·5066, was obtained, which by catalytic reduction gave a dihydrosesquicamphenol, b. p. 150—152°/12 mm., d_4^{15} 0·9510, n_D^{15} 1·4892; whilst from a crude fraction of alcohols, b. p. 140—170°/12 mm., the secondary alcohol appeared to be a mixture of $C_{15}H_{26}O$ and $C_{15}H_{24}O$. One of these alcohols is of the cadinene type. The tertiary alcohol fraction, obtained from the sesquiterpene alcohols purified through the benzoate, had b. p. 156°/12 mm., d_4^{20} 0·9665, n_D^{20} 1·5050, and by dehydrogenation gave both eudaline and cadaline. Two tertiary sesquiterpene alcohols are therefore present in camphor oil.

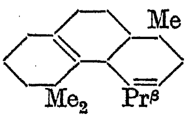
E. H. R.

Higher Terpene Compounds. XXI. Constitution and Isomerisation of α-Camphorene. L. Ruzicka and M. Stoll (*Helv. Chim. Acta*, 1924, 7, 271—282).—α-Camphorene, the diterpene found by Semmler and Rosenberg in camphor oil (A., 1913, i, 378), is known to be a monocyclic compound related to myrcene, but its constitution has not been determined. Myrcene is probably a mixture of isomerides, $CMe_2{:}CH{\cdot}[CH_2]_2{\cdot}C({:}CH_2){\cdot}CH{:}CH_2$ (I) and $CH_2{:}CMe{\cdot}[CH_2]_3{\cdot}C({:}CH_2){\cdot}CH{:}CH_2$ (II), but experiments on its decomposition by ozone indicate that (I) predominates, since only succinic acid was obtained and no trace of glutaric acid. Assuming that myrcene polymerises to α-camphorene by a process similar to the polymerisation of isoprene to dipentene, the annexed formula is obtained for α-camphorene. This formula harmonises with the physical constants of α-camphorene, and with its isomerisation products. When boiled with 95% formic acid, α-camphorene is converted into a *bicyclic diterpene*, a viscous oil, b. p. 192—194°/12 mm., d_4^{14} 0·9086, n_D^{14} 1·5104. The side chain 1 of the above formula has the configuration of a geranyl derivative, and ring closure is to be expected. More prolonged heating of α-camphorene or of the bicyclic compound with formic acid results in the formation of a *tricyclic diterpene*, b. p. 180—181°/12 mm., d_4^{14} 0·9475, n_D^{14} 1·5201. In the above formula, the ring 2 and the first three carbon atoms of side chain 3 have the dipentene structure, and a wandering of the

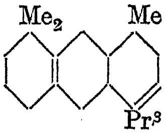


double bond into the ring may take place, analogous to the isomerisation of dipentene to α- and γ-terpenes. This would give configurations leading, after ring closure, to the formation of either a phenanthrene or an anthracene derivative,

(III.)



or



(IV.)

By oxidation with manganese dioxide and sulphuric acid the tricyclic α-camphorene gave, besides mellophanic acid, which might result from either formula, pyromellitic acid, which can, as far as is known, only result from the anthracene structure. It is probable, therefore, that the tricyclic compound has structure IV, for which the name isotricyclo*camphorene* is proposed, III being designated tricyclo*camphorene*. By catalytic hydrogenation, only two atoms of hydrogen were taken up, *dihydro*(?iso)tricyclo*camphorene* being formed, a colourless, viscous oil, b. p. 176°/12 mm., d_4^{14} 0·9410, n_D^{14} 1·5118. Oxidation of octahydro-α-camphorene with manganese dioxide and sulphuric acid gave, besides mellophanic acid and pyromellitic acid, terephthalic acid, which is additional evidence in support of the suggested α-camphorene formula. To the two known types of the diterpene series, the abietic acid and dextropimaric acid types, must now be added the camphorene type; in all of these the carbon skeleton is composed of four associated isoprene residues. (Cf. A., 1923, i, 818—819.) E. H. R.

Classification of the Resinic Acids from Conifers. O. Aschan (*Chem.-Ztg.*, 1924, **48**, 149—150).—The acids occurring in pine resins together with some of their derivatives may be divided into three classes, viz., the natural acids such as pimaric and sapic acids; the colophony acids (*iso*pimaric and abietic acids) which are formed by heating the natural sapic acids; and the sylvic acids formed by treating other resinic acids with mineral acids. Of the acids of the first group, the pimaric acids are stable in the air and difficultly soluble in organic solvents, have high melting points, and absorb two atoms of hydrogen in the presence of platinum black; the sapic acids, on the other hand, are very unstable, have low melting points, and dissolve readily in organic solvents. The *iso*pimaric acids are unstable in air, absorb two or four atoms of hydrogen, are fairly easily soluble in hot organic solvents, and melt between 150° and 160°, whilst the abietic acids absorb only two atoms of hydrogen, are difficultly soluble in organic solvents, and melt at about 200°. The true sylvic acids formed by treating the natural acids with hydrochloric or sulphuric acid are stable in the air, absorb four atoms of hydrogen or four hydroxyl groups when treated with permanganate, are difficultly soluble in organic solvents, and have high melting points, whilst the *iso*sylvic acids, formed by splitting off water or hydrogen halide from the corresponding additive products of other resinic acids, are relatively easily soluble in organic solvents and have low melting points. A. R. P.

Synthesis of 7-Ethoxy-4′-dimethylaminoflavone. H. Nägeli and J. Tambor (*Helv. Chim. Acta*, 1924, 7, 333—336).—Condensation of *p*-dimethylaminobenzaldehyde in alcoholic potassium hydroxide solution with resacetophenone monoethyl ether (2-hydroxy-4-ethoxyacetophenone) gives *2-hydroxy-4-ethoxy-4′-dimethylaminochalkone* (*2-hydroxy-4-ethoxyphenyl 4-dimethylaminostyryl ketone*), red needles, m. p. 149°, giving an intense green fluorescence in organic solvents. The *acetyl* derivative forms yellow needles, m. p. 88°. Treatment of the acetyl compound in carbon tetrachloride solution with pyridine dibromide gave a chalkone dibromide which, without further examination, was converted by alcoholic potassium hydroxide into *7-ethoxy-4′-dimethylaminoflavone*, orange needles, m. p. 183°. Its solution in concentrated sulphuric acid is yellow with a weak green fluorescence; in organic solvents the fluorescence is intense.

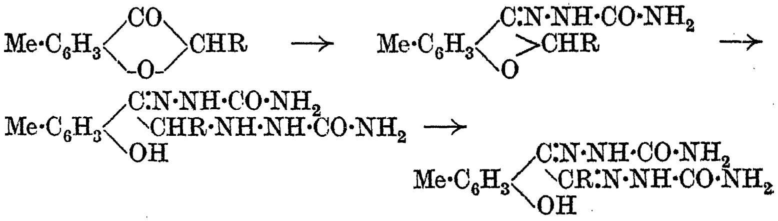
2 : 4-*Diethoxyphenyl 4-dimethylaminostyryl ketone*, from resacetophenone diethyl ether, as above, forms bright yellow needles, m. p. 128°. o-*Hydroxyphenyl* p-*dimethylaminostyryl ketone* forms red needles, m. p. 176°. The corresponding p-*hydroxyphenyl* p-*dimethylaminostyryl ketone* forms orange leaflets, m. p. 205°; *acetyl* derivative, brownish-yellow needles, m. p. 136°; *methyl* ether, yellow leaflets, m. p. 126°; *ethyl* ether, orange leaflets, m. p. 113°. 2 : 3-*Dimethoxyphenyl* p-*dimethylaminostyryl ketone* forms brown needles, m. p. 80°, and o-*anisyl* p-*dimethylaminostyryl ketone*, yellow leaflets, m. p. 101°. E. H. R.

Action of the Oxides and the Oxy-acids of Nitrogen on Diphenylene Oxide. H. Ryan and N. Cullinane (*Sci. Proc. Roy. Dubl. Soc.*, 1924, **17**, 321—326).—Whilst diphenylene oxide is unaffected by mixtures of cold nitric and glacial acetic acids, nitric acid in carbon tetrachloride solution, fuming nitric acid in warm acetic acid solution, nitrous fumes, or nitrogen peroxide in carbon tetrachloride or acetic acid, converts it mainly into 3-nitrodiphenylene oxide (cf. Borsche and Bothe, A., 1908, i, 528). Gaseous nitrogen peroxide gives the 3 : 6-dinitro derivative (Mailhe, A., 1912, i, 548), which also results when the mononitro derivative is nitrated. By still more vigorous nitration, first 1 : 3 : 6(?)-*trinitrodiphenylene oxide* (blunt prisms, m. p. 223°), and then 1 : 3 : 6 : 8(?)-*tetranitrodiphenylene oxide* (colourless plates, m. p. 283°) are produced (cf. Mailhe, *loc. cit.*; Borsche and Scholten, A., 1917, i, 390).
W. A. S.

Valency Requirements of Alkyl [Radicals]. K. von Auwers and G. Wegener (*J. pr. Chem.*, 1923, [ii], **106**, 226—252).—When the silver compound of benzamide is treated with methyl iodide at the ordinary temperature, 52% undergoes change in 11 days, the product affording, with picric acid, ammonium and benzimino methyl ether picrates. When ethyl iodide is used (91% interaction in 5·5 days) the corresponding products are ethyl benzoate, benzonitrile, ammonium picrate, and benzimino ethyl ether dipicrate (?), m. p. 146—147°. When allyl iodide is used, the initial products isolated are benzamide and benzimino *n*-propyl ether (a colourless oil, b. p. 113—116°/12 mm.), the latter with picric acid affording ammonium picrate (cf. Wheeler, A., 1898, i, 185). In none of the above cases were *N*-ethers, described by Wheeler, detected.

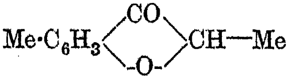
s-Formylphenylhydrazine, when treated with methyl iodide in presence of sodium ethoxide, gives a mixture of products; with allyl bromide as alkylating agent the hydrazine is rapidly and quantitatively converted into *β-formyl-α-allyl-α-phenylhydrazine*, white prisms, m. p. 57—58°, b. p. 183°/13 mm. When benzyl chloride is used, *β-formyl-α-benzyl-α-phenylhydrazine* (white prisms, m. p. 108—109°) is formed.

The authors have studied the scission of 4-methyl-1-alkylcoumaranones, using semicarbazide:

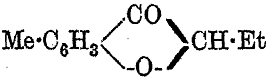


$$\mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{CO}\\ \mathrm{O}\end{array}\right\rangle\mathrm{CHR} \longrightarrow \mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{C{:}N{\cdot}NH{\cdot}CO{\cdot}NH_2}\\ \mathrm{O}\end{array}\right\rangle\mathrm{CHR} \longrightarrow \mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{C{:}N{\cdot}NH{\cdot}CO{\cdot}NH_2}\\ \mathrm{CHR{\cdot}NH{\cdot}NH{\cdot}CO{\cdot}NH_2}\\ \mathrm{OH}\end{array}\right. \longrightarrow \mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{C{:}N{\cdot}NH{\cdot}CO{\cdot}NH_2}\\ \mathrm{CR{:}N{\cdot}NH{\cdot}CO{\cdot}NH_2}\\ \mathrm{OH}\end{array}\right.$$

The coumaranone (1 mol.) was left in aqueous-alcoholic solution at 45—50° in presence of 2·5 mols. of semicarbazide hydrochloride and sodium acetate and the time required for the initial separation of the disemicarbazone noted. The times (hours) required were as follows: R=Me, 4; R=Et, 14; R=Prᵅ, 4; R=PrᵅCH₂·, 6·5; R=*n*-pentyl, 7·5; R=Ph·CH₂, 14·5. These results agree well with those *e.g.* of Meerwein (A., 1920, i, 2), as is evident from the following formulæ:



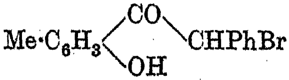
$$\mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{CO}\\ \mathrm{O}\end{array}\right\rangle\mathrm{CH{-}Me}$$



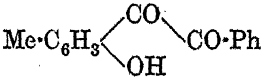
$$\mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{CO}\\ \mathrm{O}\end{array}\right\rangle\mathrm{CH{\cdot}Et}$$

A phenyl radical (possessing greater valency requirements than an alkyl radical) in position 1 facilitates scission of coumaranones to such an extent that it is impossible to convert (I) into 1-phenyl-

(I.)



$$\mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{CO{\cdot}CHPhBr}\\ \mathrm{OH}\end{array}\right.$$



$$\mathrm{Me{\cdot}C_6H_3}\left\langle\begin{array}{l}\mathrm{CO{\cdot}CO{\cdot}Ph}\\ \mathrm{OH}\end{array}\right.$$

(II.)

coumaranone satisfactorily, the latter substance being accompanied by (II) and a little *o*-benzoyl-*p*-cresotic acid (produced by the oxidation of 1-phenylcoumaranone). Since coumaranones not alkylated in position 1 cannot be split with semicarbazide, hydrogen must have a lower valency requirement than an alkyl radical. 1 : 1-Dialkylcoumaranones are less readily split by reagents than coumaranone itself, only giving monosemicarbazones with difficulty; this is probably due to steric hindrance. Coumaranones containing the 1-grouping >CR(OR), where R=H or alkyl, are readily split, but this may be attributed to the interaction of the ·OR radical with semicarbazide.

The authors compare and contrast the scission of coumaranones with that of benzoxazoles (Skraup, A., 1919, i, 598) and of phthalides (Teppema, A., 1923, i, 256), from the point of view of valency requirements of the groups present.

A number of new compounds are described: *α-Bromo-*n*-valeryl bromide* is a colourless liquid, b. p. 190°; *α-bromo-*n*-hexanoyl bromide* is a colourless liquid, b. p. 201—210°/ordinary press. (decomp.) or 85—90°/12—13 mm.; *α-bromo-*n*-heptanoyl bromide*, a pale yellow liquid, has b. p. 101—102°/9 mm.; *α-bromopalmityl bromide* is a white solid, charring when heated. These bromides, condensed with *p*-cresol methyl ether (A., 1918, i, 27), give rise to ketones: *3-α-bromo-*n*-valeroyl-*p*-cresol* forms yellow plates, m. p. 51—52°; *3-α-bromo-*n*-hexanoyl-*p*-cresol*, yellow needles, has m. p. 30·5—31·5°; *3-α-bromo-*n*-heptanoyl-*p*-cresol*, yellow needles, has m. p. 49—50°; *3-α-bromopalmitoyl-*p*-cresol* forms yellow crystals, m. p. 46—47°. The ketones, with alcoholic sodium acetate, afford coumaranones: *4-methyl-1-*n*-propylcoumaranone*, a yellow oil, has b. p. 133—134°/11 mm., d_4^{20} 1·064, n_{He}^{20} 1·5445; *4-methyl-1-*n*-butylcoumaranone*, a yellow oil, has b. p. 166—168°/17 mm., and cannot be purified through the semicarbazone, since the disemicarbazone is formed even in the cold; *4-methyl-1-*n*-pentylcoumaranone*, a yellow oil, has b. p. 175°/18 mm.; *4-methyl-1-*n*-tetracaidecylcoumaranone* forms waxy white crystals, m. p. 68—69°, and when heated in alcoholic solution with *p*-nitrophenylhydrazine hydrochloride affords the pp-*dinitro-osazone* of p-*cresyl tetracaidecyl ketone*, $OH\cdot C_6H_3Me\cdot C(:N\cdot NH\cdot C_6H_4\cdot NO_2)\cdot C(:N\cdot NH\cdot C_6H_4\cdot NO_2)\cdot C_{14}H_{29} + 1(\text{or } 2)H_2O$, red crystals, m. p. 164—165° (with previous softening); *4-methyl-1-benzylcoumaranone*, from 2-hydroxy-4-methylcoumarilic ester, sodium ethoxide, and benzyl chloride, forms white prisms or needles, m. p. 50—51°, b. p. 200—210°/13—14 mm. The benzyl compound is accompanied by *2-benzoxy-4-methylcoumarilic acid*, white needles, m. p. 146—147°, and is converted by *p*-nitrophenylhydrazine hydrochloride into the pp-*dinitro-osazone* of p-*cresyl benzyl diketone*, decomp. 223° (if heated rapidly). *4-Methyl-1:1-dibenzylcoumaranone* forms colourless needles or rhombohedra, m. p. 122—123°.

The following were obtained by treating coumaranones with semicarbazide: *disemicarbazone* of p-*cresyl* n-*propyl diketone*, decomp. 212—213° (rapid heating); *disemicarbazone* of p-*cresyl* n-*butyl diketone*, m. p. or decomp. 213—214° (rapid heating); *disemicarbazone* of p-*cresyl* n-*pentyl diketone*, m. p. 208—216°; *disemicarbazone* of p-*cresyl benzyl diketone*, m. p. 222° (rapid heating).

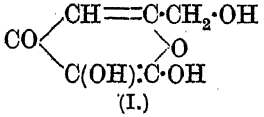
E. E. T.

Hydroxyhydrindone and Chromanone. F. Mayer and L. van Zütphen (*Ber.*, 1924, 57, [*B*], 618).—The product, m. p. 111°, obtained by the action of aluminium chloride on *o*-β-chloropropionylphenol and considered to be 4-ketochroman (Mayer and van Zütphen, this vol., i, 410) is shown to be 7-hydroxy-α-hydrindone (Knake and Salkowski, A., 1916, i, 820; von Auwers and Hilliger, A., 1917, i, 38).

H. W.

Synthesis of 7-Methoxychromanone. A. E. TSCHITSCHIBABIN (*Ber.*, 1924, **57**, [*B*], 617).—The synthesis of 7-methoxychromanone by Pfeiffer and Oberlin (cf. this vol., i, 413) from resorcinol monomethyl ether and iodopropionic acid had already been effected by Tschitschibabin and Nikitin in 1911 (A., 1911, i, 1007). F. A. M.

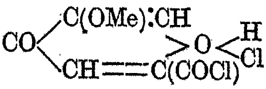
The Constitution of Kojic Acid, a γ-Pyrone Derivative formed by *Aspergillus oryzæ* from Carbohydrates. T. YABUTA (*J. Chem. Soc.*, 1924, **125**, 575—587).—Previous work (A., 1922, i, 939) has shown that kojic acid (I) is probably the alcohol corresponding with comenic acid. Interconversion by oxidation of kojic acid or reduction of comenic acid has not been accomplished, but both compounds furnish the same 4 : 5-dihydroxy-2-methylpyridine. Kojic acid on treatment with thionyl chloride yields 5-*hydroxy*-2-*chloromethyl*-γ-*pyrone*, needles, m. p. 166—167°. The latter gives the corresponding 5-*benzoyloxy* derivative, prisms, m. p. 117—118°, and the 5-*methoxy* derivative, needles, m. p. 119—121°, and on reduction with zinc dust and acetic acid gives allo*maltol* (5-hydroxy-2-methyl-γ-pyrone), prisms, m. p. 166°. *Allo*maltol is distinct from maltol (Brand, A., 1894, i, 270) and from *iso*maltol (Backe, A., 1910, i, 225, 544), the distinction being confirmed by the preparation of the following derivatives. Allo*maltol methyl* ether (5-methoxy-2-methyl-γ-pyrone), prisms, m. p. 70—71°, b. p. (approx.) 93°/0·1 mm.; *benzoyl*allo*maltol* (3-benzoyloxy-6-methyl-γ-pyrone), prisms, m. p. 128—129°; *phenylcarbamate* of allo*maltol*, $NHPh\cdot CO\cdot C_6H_5O_3$, plates, m. p. 186—188°; *bromo*allo*maltol* (6-bromo-5-hydroxy-2-methyl-γ-pyrone), crystals, m. p. 171—173°. *Benzeneazo*allo*maltol* (6-benzeneazo-5-hydroxy-2-methyl-γ-pyrone), by treating *allo*maltol in solution with diazobenzene acetate, forms reddish-brown needles, no definite m. p.



(I.)

Oxidation of the following kojic acid derivatives did not give the corresponding comenic acid derivatives: monobenzoyl kojic acid; *monoethyl ether* of *kojic acid* (5-ethoxy-2-hydroxymethyl-γ-pyrone), prepared by the interaction of kojic acid, ethyl *p*-toluenesulphonate, and sodium ethoxide in alcohol, needles, m. p. 110°; 5-*ethoxy*-2-*hydroxymethyl*-4-*pyridine*, prepared from kojic acid monoethyl ether, and isolated as the *picrate*, needles, m. p. 184—185°; 5-hydroxy-2-chloromethyl-γ-pyrone and its methyl ether; 5-*hydroxy*-2-*iodomethyl*-γ-*pyrone*, prepared from the corresponding chloro-compound as crystalline plates; 5-*methoxy*-2-*iodomethyl*-γ-*pyrone*, prisms, m. p. 135—137°.

The following derivatives of comenic acid were prepared, but reduction did not give the corresponding kojic acid derivatives. *Benzoylcomenic acid*, prisms from alcohol, m. p. 227—228°; *methyl ether* of *comenic acid*, prisms, m. p. 280—282°; *methyl ether* of *methyl comenate*, m. p. 197°; *methyl ether* of *ethyl comenate*, m. p. 156°; the *hydrochloride* of the *methyl ether* of *comenyl chloride* (II), prepared by the



(II.)

action of thionyl chloride on comenic acid methyl ether, prisms, m. p. 103°; the *methyl ether* of *comenyl chloride*, prepared from the previous compound by the action of sodium acetate, m. p. 148°; *comenamide methyl ether*, prepared by the action of ammonia on (II), needles, m. p. 178°. The catalytic reduction of the methyl ether of comenyl chloride by Rosenmund's method (A., 1918, i, 300; 1921, ii, 320, 392) failed owing to the instability of the pyrone nucleus. *Comenamic acid methyl ether* (5-methoxy-4-pyridone-2-carboxylic acid) was prepared by the action of ammonia on comenic acid methyl ether; *ammonium* salt, needles, m. p. 269°; *hydrochloride*, prisms. Thionyl chloride introduces chlorine into the 4-position of the methyl ether, giving 4-*chloro*-5-*methoxypyridine*-2-*carboxylic acid chloride*, which Rosenmund's method also failed to reduce. The acid chloride was converted into 4-*chloro*-5-*methoxypyridine*-2-*carboxylic acid*, prisms, m. p. 209°, into the *amide*, needles, m. p. 207—208°, into the *methyl* ester, prisms, m. p. 167°, and into the *ethyl* ester, prisms, m. p. 140°.

*allo*Maltol methyl ether, prepared either by the methylation of *allo*maltol or by the reduction of 5-methoxy-2-chloromethyl-4-pyrone, when heated with ammonia in a closed tube at 100° gives 5-*methoxy*-2-*methyl*-4-*pyridone*, needles, m. p. 115°, which gives a *picrate*, needles, m. p. 205—206°. The dimethyl ether of kojic acid, when similarly treated, yields the corresponding pyridine derivative, which distils at 200°/1 mm., and on heating with red phosphorus and hydriodic acid gives 4 : 5-*dihydroxy*-2-*methyl pyridine*, prisms, decomp. 280°, and crystallising $+1H_2O$ at low temperatures.

Comenic acid when heated with ammonia under pressure gives comenamic acid, which when treated with phosphorus pentachloride and then reduced with tin and hydrochloric acid gives the same 4 : 5-dihydroxy-2-methylpyridine. The dihydroxypicolines obtained thus from both acids gave on methylation the same 5-*methoxy*-1 : 2-*dimethyl*-4-*pyridone* ($+3H_2O$), colourless needles, m. p. 98°. This compound is also formed by treating *allo*-maltol methyl ether with methylamine, thus confirming the position of the methyl groups. Comenamic acid on methylation gives similarly 5-*methoxy*-1-*methyl*-4-*pyridone*-2-*carboxylic acid* ($+4H_2O$), needles, m. p. 208°. F. G. M.

Action of Sodium Sulphite on Coumarins. B. B. DEY and K. K. ROW (*J. Chem. Soc.*, 1923, **125**, 554—564).—Coumarins and many substituted coumarins react readily with sodium hydrogen sulphite to give β-sulphonic acids, *e.g.*,

$$OH\cdot C_6H_4\cdot CH(SO_3Na)\cdot CH_2\cdot CO_2H,xH_2O.$$

These yield halogen and nitro derivatives, which when heated with sulphuric acid give sulphur dioxide and the corresponding *Bz*-substituted coumarins, and when heated with potassium hydroxide solution give the corresponding potassium coumarates. The ethers of coumarinic acid when boiled with sodium hydrogen sulphite solution and then with sodium hydroxide solution give the corresponding ethers of coumaric acid.

Thus coumarin when boiled with aqueous sodium hydrogen sulphite gives *sodium dihydrocoumaric acid* β-*sulphonate*, colourless plates from water, decomp. 175—176° (*potassium*, *barium*, and *calcium* salts described). 6-Nitrocoumarin gives *sodium* 5-*nitrodihydrocoumaric acid* β-*sulphonate*, whilst 3-chloro- and 3-bromo-coumarin both give benzfuran-2-carboxylic acid (cf. Fittig, A., 1883, 474). 3 : 6-Dinitrocoumarin gives 5-nitrosalicylaldehyde, whilst *o*-coumaric acid behaves like coumarin itself. 3-Acetylcoumarin gives *sodium* α-*acetyldihydrocoumaric acid* β-*sulphonate*, white crystals, m. p. 163° (decomp.). Sodium dihydrocoumaric acid β-sulphonate when treated in aqueous solution with chlorine gives *sodium* 3 : 5-*dichlorodihydrocoumaric acid* β-*sulphonate* (colourless needles), which on heating alone or with sulphuric acid gives sulphur dioxide and 6 : 8-*dichlorocoumarin*, crystalline nodules, m. p. 160°, subliming at 130—135° in colourless needles. Bromine similarly gives *sodium* 3 : 5-*dibromodihydrocoumaric acid* β-*sulphonate* (plates), which on heating gives 6 : 8-*dibromocoumarin*, needles, m. p. 176°. Iodine gives *sodium* 5-*iododihydrocoumaric acid* β-*sulphonate*, colourless plates, which on heating yields 6-*iodocoumarin*, needles, m. p. 165°.

Sodium 5-nitrodihydrocoumaric acid β-sulphonate on bromination gives *sodium* 3-*bromo*-5-*nitrodihydrocoumaric acid* β-*sulphonate*, colourless plates, decomp. 210°, on iodination *sodium* 3-*iodo*-5-*nitrodihydrocoumaric acid* β-*sulphonate*, and on treatment with fuming nitric acid gives *sodium* 3 : 5-*dinitrodihydrocoumaric acid* β-*sulphonate*.

8-*Bromo*-6-*nitrocoumarin*, colourless needles from acetic acid, m. p. 200°, is obtained by heating the corresponding sodium dihydrocoumaric acid β-sulphonate with sulphuric acid, and on reduction with 5% acetic acid and iron filings gives 8-*bromo*-6-*aminocoumarin*, yellow needles, m. p. 200°. The latter gives an *acetyl* derivative, colourless needles, m. p. 249°, a *benzoyl* derivative, needles from acetic acid, m. p. 217°, a *hydrochloride*, colourless prisms, darkening at 235°, m. p. 246° (decomp.), and a *picrate*, yellow needles, m. p. 180—181° (decomp.). 8-*Iodo*-6-*nitrocoumarin*, similarly prepared, colourless needles, m. p. 249° (decomp.), on reduction gives 8-*iodo*-6-*aminocoumarin*, orange-yellow needles, m. p. 210°, which yields an *acetyl* derivative, needles, m. p. 275° (decomp.). 6 : 8-*Dinitrocoumarin*, similarly prepared, forms yellow needles, m. p. 158°.

The following *o*-coumaric acids were prepared by treating the corresponding sodium dihydrocoumaric acid β-sulphonates with boiling 20% potassium hydroxide solution and then acidifying. The acids on fusion with potassium hydroxide lose carbon dioxide, giving styrene derivatives. 5-*Chlorocoumaric acid*, needles, m. p. 228° (decomp.); 5-*bromocoumaric acid*, needles, m. p. 224° (decomp.); 3 : 5-*dichlorocoumaric acid*, crystals, m. p. 242° (decomp.), *methyl* ester, colourless needles, m. p. 176°; 3 : 5-*dibromocoumaric acid*, needles, m. p. 238° (decomp.), *methyl* ester, needles, m. p. 173°, *ethyl* ester, spear-shaped crystals, m. p. 128°, *acetyl* derivative, needles, m. p. 201°. 5-*Nitrocoumaric acid*, colourless needles,

m. p. 247° (decomp.), *silver* salt, insoluble and orange-coloured, *methyl* ester, colourless needles, m. p. 211°, *acetyl* derivative, needles, m. p. 217°, immediately resolidifying, and melting again at 259°. 3-*Bromo*-5-*nitrocoumaric acid*, colourless needles, m. p. 234° (decomp.), *methyl* ester, needles, m. p. 212°, *ethyl* ester, fern-shaped crystals, m. p. 184°, *acetyl* derivative, needles, m. p. 186° (decomp.). 5-*Nitro*-4-*methylcoumaric acid*, colourless needles, m. p. 219° (decomp.), *silver* salt, deep orange-red, *methyl* ester, needles, m. p. 187°, *ethyl* ester, needles, m. p. 160°; the acid itself, on fusion with potassium hydroxide, gives 5-nitro-2-methoxy-4-methylcinnamic acid, *methyl* ester, needles, m. p. 136°.

The methyl ethers of coumarinic and 5-nitrocoumarinic acids when boiled with 20% sodium sulphite solution were smoothly converted into the ethers of the corresponding coumaric acids.

α-*Naphthacoumaric acid*, prepared from α-naphthapyrone, needles, m. p. 167° (decomp.), *silver* salt, pale yellow. 4-*Nitro*-α-*naphthacoumaric acid*, prepared from 6-nitronaphthapyrone, small crystals, m. p. 179—180° (decomp.), *silver* salt, orange.

An aqueous solution of α-1 : 8-*iso*naphthoxazone when boiled with sodium sulphite and then with potassium hydroxide, and finally neutralised, gave 6-*hydroxyquinoline*-5-β-*acrylic acid*, $OH \cdot C_9H_5N \cdot CH\colon CH \cdot CO_2H$, white powder, m. p. 220° (decomp.); *silver* salt, pale yellow. The acid, when heated with sulphuric acid, gave the original *iso*naphthoxazone. F. G. M.

Fluorescence. J. TRÖGER and O. GRÜNTHAL (*J. pr. Chem.*, 1923, [ii], **106**, 173—202; cf. A., 1923, i, 355).—The authors have prepared a number of arylsulphonearylideneacetonitriles of the type $R \cdot CH\colon C(SO_2R')CN$ (cf. A., 1908, i, 798), and recorded the fluorescence (if any) of their solutions in concentrated sulphuric acid, glacial acetic acid, etc. R=2-hydroxy-1-naphthyl, R′=Ph, lemon-yellow prisms, m. p. 221° (decomp.): this *nitrile* gives an intense green fluorescence in cold glacial acetic acid; the green fluorescence observed in concentrated sulphuric acid becomes blue on standing, probably owing to the formation of 2-benzenesulphonyl-4 : 3-β-naphthapyrone, which results when the yellow compound is heated with acetic anhydride. R=2-hydroxy-1-naphthyl, R′=*p*-tolyl: this *nitrile* [lemon-yellow prisms, m. p. 232° (decomp.)] exhibits fluorescence similar to the last compound and with acetic anhydride affords 2-*p*-toluenesulphone-*p*-naphthapyrone. R=2-hydroxy-1-naphthyl, R′=*p*-chlorophenyl: this *nitrile* [lemon-yellow prisms, m. p. 254° (decomp.)] shows fluorescence as above, and with acetic anhydride gives 2-*p*-chlorobenzenesulphonyl-β-naphthapyrone. R=2-hydroxy-1-naphthyl, R′=*o*-anisyl: this *nitrile* [sulphur-yellow prisms, m. p. 241° (decomp.)] exhibits fluorescence as above and is converted by acetic anhydride into 2-*o*-*anisylsulphone*-β-*naphthapyrone*, reddish-yellow prisms, m. p. 280° (decomp.). R=2-hydroxy-1-naphthyl, R′=β-naphthyl: this *nitrile* [yellow prisms, m. p. 198° (decomp.)] exhibits fluorescence as above and with acetic anhydride affords 2-β-*naphthalenesulphonylnaphthapyrone*, yellow prisms, m. p. 234° (decomp.). R=2-methoxy-

1-naphthyl, R′=Ph: this *nitrile* (prisms, m. p. 188°) shows the above type of fluorescence. R=2-methoxy-1-naphthyl, R′=*p*-tolyl: this *nitrile* (yellow prisms, m. p. 197°) develops fluorescence slowly in the above solvents, as is the case with the *nitrile* (sulphur-yellow prisms, m. p. 206°) having R=2-methoxy-1-naphthyl and R′=*p*-chlorophenyl. R=2 : 7-dihydroxynaphthyl, R′=*p*-tolyl: this *nitrile* [yellowish-green prisms, m. p. 288° (decomp.)] shows no fluorescence in sulphuric acid solution, owing to the fact that 9-acetoxy-2-*p*-toluenesulphonyl-β-naphthapyrone (m. p. 251°), which results when it is heated with acetic anhydride, is non-fluorescent under similar conditions. The *nitrile* having R=2 : 7-dihydroxynaphthyl and R=Ph forms brownish-green prisms, m. p. 246° (decomp.), and behaves similarly to the tolyl derivative. Other *nitriles* giving non-fluorescent solutions in sulphuric acid are those in which R=*o*-hydroxyphenyl, R′=Ph (white crystals, m. p. 160°), and R=*m*-acetoxyphenyl, R′=*p*-tolyl (grey leaflets, m. p. 134°). The *nitrile* containing R=2 : 5-dihydroxyphenyl, R′=*p*-tolyl [yellow needles, m. p. 224° (decomp.)], develops very little fluorescence and on boiling in alcoholic solution passes into 3-*p*-toluenesulphonyl-6-hydroxycoumarin, the latter substance possessing very slight fluorescent properties. The *nitriles* (canary-yellow prisms, m. p. 159° and 150°, respectively) containing R=2 : 5-dimethoxyphenyl, R′=Ph, and R=2 : 5-dimethoxyphenyl, R′=*p*-tolyl, develop fluorescent effects slowly in acid solution. The *nitriles* containing R=3 : 4-dihydroxyphenyl, R′=*p*-tolyl [yellow prisms, m. p. 183° (decomp.)], and R=3 : 4-methylenedioxy, R′=*p*-tolyl (pale yellow leaflets, m. p. 168°) exhibit no fluorescent effects. On the other hand, when R=2 : 4-dihydroxyphenyl, R′=Ph (yellow prisms, m. p. 237°), marked fluorescence is shown by the *nitrile* in sulphuric acid solution. Moderate fluorescent effects are observed with the *nitrile* having R=2 : 4-dihydroxyphenyl, R′=*p*-tolyl [yellow prisms, m. p. 247° (decomp.)], this nitrile being converted by acetic anhydride into 3-*p*-toluenesulphonyl-7-acetoxycoumarin. Similar properties apply to the *nitrile* in which R=2 : 4-dihydroxyphenyl, R′=*p*-chlorophenyl [sulphur-yellow prisms, m. p. 232° (decomp.)], this compound passing, in boiling alcoholic solution, into 3-*p*-chlorobenzenesulphonyl-7-hydroxycoumarin (m. p. 232°). A sulphuric acid solution of the *nitrile* having R=2 : 4-dihydroxyphenyl, R′=*o*-anisyl (yellow prisms, m. p. 198°) slowly develops fluorescence. The following *nitriles* show no fluorescence: (1) R=2 : 4-dihydroxyphenyl, R′=β-naphthyl, sulphur-yellow prisms, m. p. 253° (decomp.), and (2), R=2 : 4-dimethoxyphenyl, R′=Ph, yellow needles, m. p. 154°.

From the above, it is seen that strongly fluorescent solutions (in concentrated sulphuric acid) are obtained from nitriles possessing a hydroxyl group in the ortho-position to the unsaturated side chain. Other theoretical points are discussed, for which the original should be consulted. E. E. T.

Attempted Syntheses of *meta*-Related Ring Systems. II. F. Reindel and L. Schuberth (*Ber.*, 1924, 57, [*B*], 369—371; cf. Reindel and Siegel, A., 1923, i, 916).—The action of *m*-xylylene bromide on pyrocatechol, resorcinol, or quinol in alcoholic solution in the presence of sodium alkoxide yields only mixtures of products which could not be purified satisfactorily. Better results are obtained with the monomethyl ethers, whereby m-*xylenyl di*-o-*anisyl ether*, $C_6H_4(CH_2·O·C_6H_4·OMe)_2$, colourless needles, m. p. 115°, and m-*xylenyl di*-p-*anisyl ether*, quadratic leaflets, m. p. 128°, are isolated; resorcinol methyl ether gives a compound, b. p. 121°/10 mm., which contains halogen. The compounds, however, are not adapted to the production of *meta*-related ring systems, since they cannot be demethylated without extensive decomposition of the molecule. Attempts to replace methyl by more readily eliminable radicals (acetyl, benzoyl, or carbethoxyl) did not lead to the desired result owing to the ready fission of the compounds into their components.

m-Dithiolbenzene is converted by *m*-xylylene bromide and sodium ethoxide in the presence of alcohol and benzene into the *meta*-cyclic *thioether*,  $C_6H_4{<}\begin{matrix}S·CH_2·C_6H_4·CH_2·S\\S·CH_2·C_6H_4·CH_2·S\end{matrix}{>}C_6H_4$, colourless needles, m. p. 235°. H. W.

Formation of Pyrrole Derivatives from Amides of β-Diketonic Esters. W. Küster and P. Schlack [with E. Erfle and W. Heess] (*Ber.*, 1924, **57**, [*B*], 409—413).—Dicarbonyl derivatives obtained from oxalic esters are not generally suited to the production of pyrrole derivatives by reason of their strongly acidic character. Attempts are described to obtain more successful results from compounds of this type in which the acidity has been diminished by the introduction of groups containing nitrogen.

Acetylpyruvanilide, $CH_2Ac·CO·CO·NHPh$, pale yellow needles, m. p. 140—141 (cf. Mumm and Bergell, A., 1912, i, 936), is readily converted into the corresponding *nitroso* derivative, $C_{11}H_{10}O_4N_2$, dark yellow prisms, m. p. 138°, which could not be caused to react with ethyl acetoacetate to yield a substituted pyrrole. A negative result was also obtained when the diketone and ethyl nitrosoacetoacetate were employed.

Ethyl oxalate condenses with acetmethylanilide in the presence of sodium ethoxide to give *ethoxalylacetmethylanilide*,

$$CO_2Et·CO·CH_2·CO·NMePh,$$

colourless needles, m. p. 75°, b. p. 112°/740 mm. (*copper* salt, $C_{26}H_{28}O_8N_2Cu$, m. p. 112—115°; and *iron* salt, $C_{39}H_{42}O_{12}N_3Fe$). Reduction of a mixture of ethyl nitrosoacetoacetate and ethoxalylacetmethylanilide by zinc dust and glacial acetic acid leads to the formation of *ethyl* 3-*carboxyphenylmethylamido*-4-*methylpyrrole*-2 : 5-*dicarboxylate*,  $\begin{matrix}C(CO·NMePh){:}C(CO_2Et)\\ CMe{=\!=\!=}C(CO_2Et)\end{matrix}{>}NH$, colourless crystals, m. p. 82°, which is hydrolysed to the corresponding dicarboxylic *acid*, m. p. 126°.

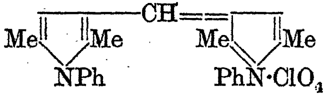
The acid character of ethyl acetylpyruvate, $CH_2Ac·CO·CO_2Et$, is demonstrated by its ability to react with precipitated ferric hydroxide to form the *iron* salt, $C_{21}H_{27}O_{12}Fe$, red, rhombic leaflets. H. W.

Synthesis of Cryptopyrrolecarboxylic Acid. (The Synthesis of the Acid Scission Products of Blood Pigment. I.) H. Fischer and B. Weiss (*Ber.*, 1924, **57**, [*B*], 602—609; cf. A., 1922, i, 759; 1923, i, 707; this vol., i, 201).—Cryptopyrrolecarboxylic acid has been synthesised in the following way: ethyl 2 : 4-dimethylpyrrole-3-aldehyde-5-carboxylate was condensed with cyanoacetic acid by means of acetic anhydride to give *ethyl* 2 : 4-*dimethyl*-3-[ω-*cyano*-ω-*carboxyvinyl*]*pyrrole*-5-*carboxylate* (yellow needles, m. p. 239°). The latter on reduction gave *ethyl* 2 : 4-*dimethyl*-3-[ω-*cyano*-ω-*carboxyethyl*]*pyrrole*, which forms crystals, m. p. 184°; this was then either (i) heated in a vacuum to give *ethyl* 2 : 4-*dimethyl*-3-ω-*cyanoethylpyrrole*-5-*carboxylate* (m. p. 134°), which was then hydrolysed by concentrated alkali, and after acidification, the crude acid heated with acetic acid and hydriodic acid, the product being cryptopyrrolecarboxylic acid; or (ii) the nitrile-carboxylic acid was (by heating with acetic and hydriodic acids) converted into cryptopyrrolecarboxylic acid. The structure of the acid is thus definitely settled. The following new compounds were also prepared: *ethyl* 2 : 4-*dimethyl*-3-ω-*nitrovinylpyrrole*-5-*carboxylate*, from the corresponding aldehyde and nitromethane or nitroacetic acid, is yellow and has m. p. 231—232°; *ethyl* 2 : 4-*dimethyl*-5-ω-*nitrovinylpyrrole*-3-*carboxylate*, m. p. 165°, was prepared from the isomeric aldehyde and nitromethane. *Ethyl* 2 : 4-*dimethyl*-3-[-*cyano*-ω-*carbethoxyvinyl*]*pyrrole*-5-*carboxylate* (the ethyl ester of the nitrile-carboxylic acid), m. p. 239°, was prepared from the same aldehyde and ethyl cyanoacetate in presence of methylamine; it forms white needles, m. p. 165°, and on hydrolysis yields 2 : 4-*dimethylpyrrole*-3-*aldehyde*-5-*carboxylic acid*, m. p. 230° (decomp.). The following compounds were similarly prepared from cyanoacetic ester and the corresponding aldehyde: 2 : 4-*dimethyl*-3-[ω-*cyano*-ω-*carbethoxyvinyl*]*pyrrole*, crystals, m. p. 121°, giving, when hydrolysed, 2 : 4-*dimethylpyrrole*-3-*aldehyde*, m. p. 126°; *ethyl* 2 : 4-*dimethyl*-5-[ω-*cyano*-ω-*carbethoxyvinyl*]*pyrrole*-3-*carboxylate*, yellow crystals, m. p. 153°; 3-*acetyl*-2 : 4-*dimethyl*-5-[ω-*cyano*-ω-*carbethoxyvinyl*]*pyrrole*, yellow crystals, m. p. 174°; 2 : 4 : 5-*trimethyl*-3-[ω-*cyano*-ω-*carbethoxyvinyl*]*pyrrole*, dark yellow crystals, m. p. 147°; *ethyl* 2 : 4-*dimethyl*-3-[ω-*cyano*-ω-*carbethoxyethyl*]*pyrrole*-5-*carboxylate*, white needles, m. p. 131°; *ethyl* 2 : 4-*dimethyl*-3-[*dicyanovinyl*]-*pyrrole*-5-*carboxylate*, m. p. 214°, from 2 : 4-dimethyl-5-carbethoxypyrrole-3-aldehyde and malononitrile in acetic anhydride; *ethyl* 4-*methyl*-3-*propionyl*-2-*ethylpyrrole*-5-*carboxylate*, from nitrosoacetoacetic ester and dipropionylmethane in glacial acetic acid with the addition of zinc dust, white needles, m. p. 112°; 5-*carbethoxy*-2 : 4-*dimethyl*-3-*pyrrylglyoxylic ester*, m. p. 133°, was prepared from ethyl 2 : 4-dimethylpyrrole-5-carboxylate and methyl cyanocarbonate in presence of hydrochloric acid. Ethyl 2 : 4-dimethyl-3-[cyanoacetyl]pyrrole-5-carboxylate reacts with hydrazine hydrate in presence of sodium ethoxide to give an oily *substance* which shows an intense pyrrole reaction; it forms a *picrate*, and an azo *dye*, m. p. 166°.

F. A. M.

Synthetic Experiments with the Fission Products of the Blood Pigments and the Formation of Complex Salts from Dipyrrylmethenes. II. H. Fischer and M. Schubert (*Ber.*, 1924, **57**, 610—617; cf. preceding abstract).—The synthesis of cryptopyrrole has been modified by heating ethyl 2 : 4-dimethyl-3-acetylpyrrole-5-carboxylate with hydrazine hydrate and sodium ethoxide at 180°. In the synthesis of cryptopyrrole-aldehyde by the Gattermann hydrocyanic acid method, *cryptopyrrole-aldimine* (isolated as the *picrate*, yellow crystals, m. p. 205°) is formed. Attempts to hydrolyse the intermediate product in the synthesis (dicryptopyrrylmethylamine) were unsuccessful, the imine, however, readily yielding cryptopyrrole-aldehyde. The amine, with semicarbazide, affords the semicarbazone of the aldehyde. 5-*Chloroacetyl*-2 : 3-*dimethyl*-4-*ethylpyrrole*, from hæmopyrrole and chloroacetonitrile, forms colourless needles, m. p. 140°. 5-*Dimethylaminoacetyl*-2 : 3-*dimethyl*-4-*ethylpyrrole hydrochloride* (colourless needles, m. p. 73°) results from chloroacetylhæmopyrrole and dimethylamine. On submitting hæmopyrrole to the Gattermann synthesis, the product consists of a mixture of *hæmopyrrole-aldimine* (*picrate*, m. p. 200°, decomp. 195—200°), and C-*dihæmopyrrylmethylamine* (*aminodihæmopyrrylmethane*), which forms colourless needles, m. p. 150°. The hæmopyrrole-aldimine, when boiled in aqueous suspension, gives 5-*formyl*-2 : 3-*dimethyl*-4-*ethylpyrrole*, colourless needles, m. p. 85° (*semicarbazone*, colourless crystals, m. p. 195°). The aldehyde, with hot concentrated hydrochloric acid, yields violet-red crystals of bis-[2 : 3-*dimethyl*-4-*ethylpyrryl*]*methene hydrochloride*, m. p. 215°. From phonopyrrolecarboxylic ester (Gattermann synthesis), *methyl hæmopyrrolecarboxylate aldimine hydrochloride* was obtained as colourless needles, m. p. 173°. In a similar manner, cryptopyrrolecarboxylic acid yielded *cryptopyrrolecarboxylic acid aldimine hydrochloride* as colourless needles, m. p. 208°, which on hydrolysis yielded 5-*formyl*-2 : 4-*dimethylpyrrole*-3-*propionic acid*, yellowish-brown needles, m. p. 151° (*semicarbazone*, m. p. 223°). The cryptopyrrolecarboxyaldehyde, on heating with dilute hydrochloric acid, yields red needles of bis-[2 : 4-*dimethyl*-3-*carboxyethylpyrryl*]*methene hydrochloride*, m. p. 235°. Cryptopyrrolecarboxy-aldehyde condenses with cryptopyrrole in presence of hydrochloric acid to give reddish-brown needles of [2 : 4-*dimethyl*-3-*carboxyethylpyrryl*]-[2 : 4-*dimethyl*-3-*ethylpyrryl*]*methene hydrochloride*, m. p. 215°. The following complex salts of *bis*-[2 : 4-dimethyl-3-carbethoxypyrryl]methene were prepared : *copper*, *nickel*, *cobalt*, and *zinc*; the *nickel*, *cobalt*, and *zinc* complex salts of *bis*-[2 : 4-dimethylpyrryl]methene were also made. F. A. M.

Di-β-pyrrylmethenes. I. H. Fischer and K. S. Smeykal (*Ber.*, 1924, **57**, [*B*], 544—550).—The condensation of ethyl 2 : 5-dimethylpyrrole-3-carboxylate with formic acid in presence of perchloric acid affords a substance, $C_{13}H_{17}N_2{\cdot}ClO_4$, orange needles, decomp. 220—230°, and possessing marked sternutatory properties. It appears to be identical with the *perchlorate* of the product obtained by Piloty (A., 1915, i, 461) by condensing 2 : 5-dimethylpyrrole with 3-formyl-2 : 5-dimethylpyrrole, which appears to be *di*-3-(2 : 5-*dimethylpyrryl*)*methene*. It was obtained also by condensing 2 : 5-dimethylpyrrole with formic acid in presence of perchloric acid. The free *base* forms orange needles charring above 200°. The *hydrochloride* forms long, red needles, the *sulphate*, small, reddish-brown needles. Ethyl 1-phenyl-2 : 5-dimethylpyrrole-3-carboxylate condenses with formic acid in presence of perchloric acid to give the *perchlorate* of a substance, $C_{25}H_{25}N_2{\cdot}ClO_4$, presumably *di*-3-(1-*phenyl*-2 : 5-*dimethylpyrryl*)*methene* (annexed formula), which forms reddish-brown leaflets, m. p. 245° (decomp.).



Diethyl 1-hydroxy-2 : 5-dimethylpyrrole-3 : 4-dicarboxylate condenses with formic acid in presence of perchloric acid to give long, red needles of the perchlorate of a substance, decomposing at 210—215°, of the formula $C_{13}H_{17}O_6N_2Cl$, probably the *perchlorate* of di-3-(1-hydroxy-2 : 5-dimethylpyrryl)methene. Ethyl 2 : 5-dimethylpyrrole-4-aldehyde-3-carboxylate undergoes auto-condensation when heated with strong hydrochloric acid to give a *hydrochloride*, red needles, m. p. 181°. The perchlorate, $C_{10}H_{23}N_2{\cdot}ClO_4$, appears to be that of *ethyl* 2 : 5 : 2′ : 5′-*tetramethyldi*-β-*pyridylmethene*-4-*carboxylate*, the base being a yellow powder charring at 220—230°. The mother-liquors contain a small amount of the base previously obtained from ethyl 2 : 5-dimethylpyrrole-3-carboxylate. F. A. M.

Catalytic Hydrogenations under Pressure in the Presence of Nickel Salts. VIII. Compounds of the Indole Series. J. VON BRAUN, O. BAYER, and G. BLESSING (*Ber.*, 1924, 57, [*B*], 392—403).—An extension of previous work (A., 1923, i, 835; this vol., i, 426). Indole resembles quinoline in that hydrogenation takes place primarily in the heterocyclic nucleus. The presence of substituents in this nucleus increases its resistance to reduction, and causes hydrogenation to occur to a greater or less extent in the benzenoid half of the molecule. As in the quinoline series, this tendency can be balanced by the introduction of substituents into the benzenoid nucleus.

Hydrogenation of the indoles was effected in decahydronaphthalene solution, generally at 220—250°. The reaction usually comes to an end before the calculated volume of hydrogen has been absorbed and, when this is the case, ammonia is also formed.

The pyrrole ring is not completely stable under the conditions of hydrogenation and yields fully hydrogenated indoles (see below) and *o*-alkylanilines, among which, *o*-iso*propylaniline*, b. p. 95°/13 mm., d_4^{12} 0·9760 (*hydrochloride*, m. p. 182°; *picrate*, m. p. 160°; *acetyl* derivative, m. p. 70°; *phenylthiocarbamide* compound, m. p. 129—130°), does not appear to have been described previously.

Indole, when hydrogenated at 225° until further absorption of gas does not occur, yields 8% of unchanged material and 66% of basic substances, whereas the remainder suffers more complete degradation accompanied by the production of ammonia. The bases consist of perhydroindole (octahydroindole), a colourless liquid with an odour of hemlock, b. p. 170—171°/760 mm., d_4^{17} 0·8845 [Willstätter and Jacquet (A., 1918, i, 392) give b. p. 182—183°/720 mm., 65°/12 mm., d_4^{21} 0·9947], which yields a chloroplatinate, m. p. 238—239° [Willstätter and Jacquet, m. p. (indefinite) 172—173°]; a *picrate*, m. p. 189—190° (Willstätter and Jacquet, m. p. about 137—138°); a quaternary *iodide*, m. p. 234° (decomp.), and a *benzenesulphonyl* derivative, m. p. 121—122°; also *o*-ethylaniline, b. p. 209—210°/760 mm., d_4^{21} 0·9769 (*hydrochloride*, m. p. 191°; *picrate*, m. p. 194—195°; *acetyl* derivative, needles, m. p. 113°; *benzoyl* derivative, m. p. 146°; *phenylthiocarbamide* compound, needles, m. p. 124°; *benzenesulphonyl* derivative, m. p. 101—102°). 2 : 3-Dihydroindole can readily be prepared by the partial hydrogenation of indole at 180°.

[In part with G. LEMKE.]—2-Methylindole is converted by hydrogen at 220° into a mixture of 2-*methyloctahydroindole* and 2-*methyl*-4 : 5 : 6 : 7-*tetrahydroindole*. The former compound is a colourless liquid with a pronounced basic odour, b. p. 62°/12 mm., d_4^{8} 0·9142; it gives a *picrate*, pale yellow prisms, m. p. 192—193°, and a *benzenesulphonyl* derivative, m. p. 110—112°. The corresponding quaternary *iodide*, m. p. 196°, is decomposed by treatment with silver oxide and subsequent distillation into an apparently homogeneous, unsaturated *base*, $NMe_2{\cdot}C_6H_8{\cdot}CH{:}CHMe$ or $C_6H_9{\cdot}CH_2{\cdot}CHMe{\cdot}NMe_2$, b. p. 80—81°/13 mm., d_4^{15} 0·8603, which yields a *picrate*, m. p. 129—130°, and a quaternary *iodide*, m. p. 187—188°. When the latter compound is treated with silver oxide and the product is distilled, *propenyltetrahydrobenzene*, $C_6H_9{\cdot}CH{:}CHMe$, b. p. 161°, d_4^{17} 0·8285, $n_D^{17{\cdot}6}$ 1·4837, is obtained. 2-Methyl-4 : 5 : 6 : 7-tetrahydropyrrole is a colourless liquid, b. p. 105°/13 mm., d_4^{10} 0·9871, which gives all the reactions characteristic of pyrroles.

3-Methylindole yields 3-*methyl*-4 : 5 : 6 : 7-*tetrahydroindole*, b. p. 105°/12 mm., d_4^{14} 0·9698, and 3-*methyloctahydroindole*, a mobile liquid, b. p. 70°/12 mm., d_4^{8} 0·8908 [*hydrochloride*, m. p. 260° (decomp.); *picrate*, m. p. 195—196°; *quaternary iodide*, $C_{11}H_{22}NI$, m. p. 190°; *benzenesulphonyl* derivative, colourless crystals, m. p. 129—130°].

1 : 2-Dimethylindole is rapidly hydrogenated at 200° to a mixture of somewhat unstable 1 : 2-*dimethyl*-4 : 5 : 6 : 7-*tetrahydroindole*, b. p. 108°/12 mm., d_4^{20} 0·9815, and 1 : 2-*dimethyloctahydroindole*, a colourless liquid with an odour of hemlock, b. p. 71°/12 mm., d_4^{20} 0·8822, which suffers partial dehydrogenation when boiled. It yields a methiodide, m. p. 197° (also obtained from 2-methyloctahydroindole), a very hygroscopic *hydrochloride*, a *chloroplatinate*, decomp. 220°, and a *picrate*, m. p. 149—150°.

2 : 5-Dimethylindole is slowly and incompletely hydrogenated at 250°. It gives small amounts of 2 : 5-dimethyloctahydroindole, which is characterised as the *benzenesulphonyl* derivative, m. p. 114°, and, preponderatingly, o-*propyl*-p-*toluidine*, a colourless liquid, b. p. 98—99°/13 mm., d_4^{12} 0·9666. The latter substance gives a *benzenesulphonyl* derivative, m. p. 104°, a *picrate*, m. p. 201°, a *hydrochloride*, m. p. 195°, a *benzoyl* derivative, m. p. 174—175°,

and a *phenylthiocarbamide* compound, m. p. 146°; the amine is converted by boiling its diazotised solution into o-*propyl*-p-*cresol*, b. p. 97°/13 mm., d_4^{22} 1·018.

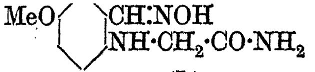
2 : 4 : 7-*Trimethylindole*, a colourless liquid which rapidly darkens in colour, b. p. 158—159°/13 mm., is prepared by the condensation of *p*-xylylhydrazine with acetone and treatment of the product with zinc chloride at 160°. It is hydrogenated to 2-*propyl*-3 : 6-*dimethylaniline*, b. p. 107—110°/13 mm., d_4^{21} 0·9680. The corresponding *picrate*, m. p. 184°, the non-crystalline *hydrochloride*, and the brownish-yellow *chloroplatinate*, decomp. 178°, are described.

H. W.

The Methoxyindoles and their Derivatives. K. G. Blaikie and W. H. Perkin, jun. (*J. Chem. Soc.*, 1924, **125**, 296—335).—2-Nitro-5-, -3-, and -6-methoxytoluenes were condensed with ethyl oxalate in presence of potassium ethoxide to form the corresponding nitromethoxyphenylpyruvic acids. 2-*Nitro*-5-*methoxyphenylpyruvic acid* forms yellow needles, m. p. 128°, and gives a *phenylhydrazone*, yellow prisms, m. p. 151—152° (decomp.). 2-*Nitro*-3-*methoxyphenylpyruvic acid* crystallises from acetic acid in yellow prisms, m. p. 118—145°, containing the solvent, which is lost at 100°, leaving the acid as an opaque, pale yellow powder, m. p. 161—162°. The *phenylhydrazone* forms yellow needles, m. p. 159° (decomp.). 2-*Nitro*-6-*methoxyphenylpyruvic acid* forms yellow, indefinite crystals containing benzene, m. p. 47—55°, which retain the solvent after several days in a vacuum. The *phenylhydrazone* forms yellow needles, m. p. 173—174° (decomp.). On oxidation with alkaline hydrogen peroxide, the above nitromethoxyphenylpyruvic acids yield, respectively, 2-*nitro*-5-*methoxyphenylacetic acid*, faintly brown needles, m. p. 176°; 2-*nitro*-3-*methoxyphenylacetic acid*, colourless needles, m. p. 137—138°; and 2-*nitro*-6-*methoxyphenylacetic acid*, bright yellow needles, m. p. 172°. On reduction with ammoniacal ferrous sulphate, the nitromethoxyphenylpyruvic acids give good yields, respectively, of 5-*methoxyindole*-2-*carboxylic acid*, colourless needles, m. p. 196—197° (decomp.) (*ethyl* and *methyl* esters, colourless needles, m. p. 156° and 177°, respectively); 7-*methoxyindole*-2-*carboxylic acid*, colourless needles, m. p. 182° (decomp. at 220—225°) (*ethyl* ester, flat, colourless needles, m. p. 114°; *methyl* ester, colourless plates, m. p. 129°); and 4-*methoxyindole*-2-*carboxylic acid*, colourless needles, m. p. 234—235° (decomp.) (*methyl* ester, colourless plates, m. p. 143·5°; *ethyl* ester, colourless needles, m. p. 161·5°). The above acids lose carbon dioxide on heating, with formation, respectively, of 5-, 7-, and 4-methoxyindoles. 5-*Methoxyindole* forms colourless needles, m. p. 55°, b. p. 176—178°/17 mm., slightly volatile in steam. It forms a *picrate*, $C_{15}H_{12}O_8N_4$, bright red needles, m. p. 145°, and a 1-*acetyl* derivative, colourless, prismatic crystals, m. p. 82°, b. p. 210—211°/25 mm. Two *nitro*-1-*acetyl*-5-*methoxyindoles* (*a*) light brown, flat needles, m. p. 149°, and (*b*) brown plates, m. p. 213—214°, are described, and afford, on hydrolysis, *nitro*-5-*methoxyindoles* (*a*) yellow needles, m. p. 144°, (*b*) m. p. 144° (mixed m. p. 112°), respectively. Application of the Tiemann-

Reimer reaction to 5-methoxyindole produced a mixture of *5-methoxyindole-3-aldehyde*, m. p. 173°, and *3-chloro-6-methoxyquinoline*, m. p. 73—74°. *7-Methoxyindole* forms a colourless syrup, b. p. 157°/17 mm. (*picrate*, $C_{15}H_{12}O_8N_4$, m. p. 156°). *7-Methoxyindole-3-aldehyde*, m. p. 159—160°, *3-chloro-8-methoxyquinoline*, m. p. 84·5°, and *4-methoxyindole*, m. p. 69·5° (*picrate*, m. p. 159—160°), are described.

5-Methoxyindole was also synthesised as follows: 2-amino-5-methoxybenzaldoxime was condensed with chloroacetamide, with formation of *4-methoxy-2-aldehydophenylglycineamide oxime* (I), yellow plates, m. p. 196° (decomp.). The *formyl* derivative (II)



(I.)

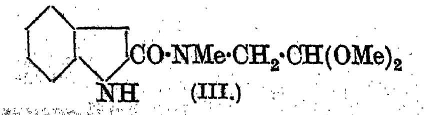
$$\mathrm{MeO{\cdot}C_6H_3}<\begin{matrix}\mathrm{CH{:}N{\cdot}O}\\ \mathrm{N(CH_2{\cdot}CO{\cdot}NH_2)}\end{matrix}>\mathrm{CH_2}$$

(II.)

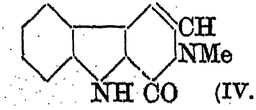
forms bright yellow needles, m. p. 233°. The oxime was hydrolysed to the *oxime* of *4-methoxy-2-aldehydophenylglycine*, pale yellow needles, m. p. 178° (slow decomp.), which was converted by the action of sulphurous acid into *4-methoxy-2-aldehydophenylglycine*, bright orange prisms, m. p. 183° (decomp.) (*phenylhydrazone*, yellow needles, m. p. 175—176°), and this, on heating with sodium acetate and acetic anhydride, yielded 1-acetyl-5-methoxyindole, from which the 5-methoxyindole was obtained on hydrolysis.

α-Ketobutyric acid p-*methoxyphenylhydrazone*, yellow plates, m. p. 105°, yields the *ethyl* ester of *5-methoxyscatole-2-carboxylic acid*, colourless needles, m. p. 151—152°, on treatment with alcoholic sulphuric acid. The free acid forms colourless needles, m. p. 200—201° (decomp.), and the *methyl* ester, colourless plates, m. p. 156°. In the same way, *α-ketobutyric acid* o-*methoxyphenylhydrazone*, pale yellow plates, m. p. 112° (*ethyl* ester, yellow prisms, m. p. 59—60°) is converted into *7-methoxyscatole-2-carboxylic acid*, colourless needles, m. p. 222—223° (decomp.) (*methyl* ester, colourless plates, m. p. 144—145°). The above methoxyscatolecarboxylic acids lose carbon dioxide on heating, with formation, respectively, of *5-methoxyscatole*, plates, m. p. 66° (*picrate*, m. p. 151—152°) and *7-methoxyscatole*, a yellow oil, b. p. 170°/20 mm. (*picrate*, m. p. 156°). The methoxy-indoles and -scatoles give deep colorations with a pine shaving moistened with hydrochloric acid, and characteristic colours, intensified in the case of the indoles by the addition of nitrite, with a solution of *p*-dimethylaminobenzaldehyde in aqueous-alcoholic hydrochloric acid (Ehrlich's reagent).

The action of alcoholic hydrogen chloride on *4-methoxyindole-2-carboxydimethylacetalylmethylamide* (III) (needles, m. p. 112°)



(III.)

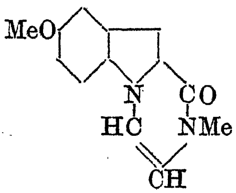


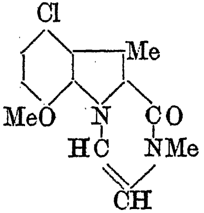
(IV.)

leads to the formation of *9-methoxy-3-keto-4-methyl-3 : 4-dihydro-4-carboline* (IV), needles, m. p. 250°, whilst *5-methoxyindole-2-carb-*

oxydimethylacetalylmethylamide (colourless plates, m. p. 159°) yields about equal proportions of 10-*methoxy*-3-*keto*-4-*methyl*-3 : 4-*dihydro*-4-*carboline*, colourless needles, m. p. 280°, and 10-*methoxy*-5-*keto*-4-*methyl*-4 : 5-*dihydroindolediazine*(1 : 4) (V), colourless, prismatic needles, m. p. 243°.

(V.)





(VI.)

7-*Methoxyindole*-2-*carboxydimethylacetalylmethylamide*, a syrup, yields about 4 parts of 12-*methoxy*-3-*keto*-4-*methyl*-3 : 4-*dihydro*-4-*carboline*, pale yellow plates, m. p. 250°, to 1 part of 12-*methoxy*-5-*keto*-4-*methyl*-4 : 5-*dihydroindolediazine*(1 : 4), four-sided prisms (hydrated), m. p. 135° (anhydrous). 5-*Methoxyindole*-2-*carboxyacetalylamide*, colourless prisms, m. p. 151—152°, yields on the same treatment only 10-*methoxy*-5-*keto*-4:5-*dihydroindolediazine*(1:4) microscopic plates, sintering at 265°, m. p. 280°, whilst 5-*methoxyindole*-2-*carboxyacetalylmethylamide*, colourless needles, m. p. 127°, yields equal quantities of the above carboline (m. p. 280°) and indolediazine (m. p. 243°). The direction of ring formation is thus dependent on the presence or absence of the methyl group in the acetalylamide chain (cf. T., 1922, **121**, 1875). The product derived similarly from 7-methoxyscatole-2-carboxylic acid contained chlorine (apparently introduced in preparing the acid chloride), and was probably 9-*chloro*-12-*methoxy*-5-*keto*-4 : 7-*dimethyl*-4 : 5-*dihydroindolediazine*(1 : 4) (VI), colourless, striated needles, m. p. 109°. It gave no colour reactions with aldehydes.

2-*Nitro*-α-*methoxycinnamic acid*, pale yellow clusters of needles, m. p. 164—165°, is obtained by methylation of the condensation product from *o*-nitrotoluene and ethyl oxalate in presence of sodium ethoxide (*methyl* ester, m. p. 67°). 2-*Amino*-α-*methoxycinnamic acid* loses acetic acid of crystallisation at 100°, forming a pale yellow, opaque powder, m. p. 167° (decomp.) (*methyl* ester, m. p. 60—61°). When treated with cold, concentrated sulphuric acid, boiled with 10% hydrochloric acid, or heated above its m. p., the acid is decomposed into methyl alcohol and indole-2-carboxylic acid. In the same way, by the methylation of metallic derivatives of ethyl nitromethoxyphenylpyruvates, 2-*nitro*-α : 5-*dimethoxycinnamic acid*, yellow needles, m. p. 198—200° (decomp.) (*methyl* ester, m. p. 113—114°; *ethyl* ester, m. p. 74·5°), and 2-*nitro*-α : 3-*dimethoxycinnamic acid*, colourless needles, m. p. 202° (decomp.) are produced. 2-*Amino*-α : 5-*dimethoxycinnamic acid* separates from acetic acid in colourless needles containing the solvent, which is lost at 100°, leaving the acid as a pale yellow, opaque powder, m. p. 173—174° (*methyl* ester, m. p. 81°). 2-*Amino*-α : 3-*dimethoxycinnamic acid* loses acetic acid of crystallisation on standing in air, is then yellow, and has m. p. 139° (decomp.). Both the above amino-acids decompose on heating into methyl alcohol and the corresponding methoxyindole-2-carboxylic acids. Scatole-2-carboxylic acid can be obtained by a similar synthesis from α-keto-β-*o*-nitrophenylbutyrate, but the corresponding methoxy derivatives could not be isolated. F. G. W.

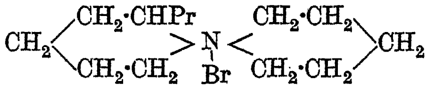
Constitution of Naphtholisatin and its Derivatives. N. Dănăilă (*Bul. Soc. Româna Stiin.*, 1923, **26**, 87—95).—A question of priority in connexion with a paper by Cândea (A., 1923, i, 246; cf. Dănăilă, A., 1916, i, 497, and Dissert., Berlin, 1909). R. B.

Oxidation of Carbazole by Silver Oxide. G. E. K. Branch and W. W. Hall (*J. Amer. Chem. Soc.*, 1924, **46**, 438—445).—In continuation of previous work on this subject, the authors have obtained three fractions B, E, and A (cf. A., 1921, i, 56). E, $C_{36}H_{27}ON_3$ (?), is a white powder, m. p. 189—197° (with charring), which reacts with bromine to give a bromide (?), m. p. 117—125°. It reacts with nitric oxide, and affords two nitroso derivatives, yellow solids, m. p. 216° (decomp.) and 228° (decomp.), respectively. Sulphuric acid converts it into an isomeric *substance*, m. p. 250°. A is a yellow powder affording a bromo derivative, m. p. 85—100°. E is considered to be an hydroxymonocarbazyldibiphenylenehydrazine in which two or three of the carbazole rings are reduced to diphenylamine nuclei, whilst B (which affords a bromo derivative, m. p. 230—245°) is an intermediate in the formation of E, the latter being formed by the combination of the reduced B radicals and the carbazyl nuclei. A. B. S.

The Chemistry of Carbazole. H. Lindemann (*Ber.*, 1924, **57**, [*B*], 555—559).—A method is described for preparing 3-nitrocarbazole from carbazole, using glacial acetic acid, sodium nitrite, and nitric acid. 3-Nitro-9-nitrosocarbazole, first obtained, when hydrolysed with alcoholic 40% potassium hydroxide, gives 3-nitrocarbazole, together with about 4% of an isomeride (1-nitrocarbazole ?) (yellow needles, m. p. 187°); the nitro compound (m. p. 164°), hitherto described as the 1-nitro compound, must therefore be either the 2- or 4-*nitrocarbazole* (cf. A., 1909, i, 961). 3-*Nitro*-N-*methylcarbazole* (yellow needles, m. p. 173°), and 3-*nitro*-N-*ethylcarbazole* (yellow needles, m. p. 128°) were prepared by alkylation of the 3-nitro compound. The nitro-*N*-methyl compound when reduced afforded 3-*amino*-9-*methylcarbazole*, grey needles, m. p. 174°. Its *salts* with mineral acids are soluble in water and give *acetyl* and *benzoyl* derivatives, m. p. 210° and 211°, respectively. 3-*Amino*-N-*ethylcarbazole* forms white needles, m. p. 113—114° (*acetyl* derivative, m. p. 190°; *benzoyl* derivative, m. p. 180°).

3-Nitro-9-ethylcarbazole, m. p. 128°, does not agree in its properties with the product obtained by Delétra and Ullmann (A., 1904, i, 272) (cf. also Stevens and Tucker, T., 1923, **123**, 2140) from 2-amino-4-nitro-*N*-ethyldiphenylamine; the latter substance, obtained by reducing the corresponding dinitro compound with sodium sulphide, forms red crystals melting at 76°. On treatment with nitrous acid the corresponding diazonium compound, 2(*phenylmethylamino*)5-*nitrophenyldiazonium nitrate*, was obtained in the form of very stable yellow needles exploding at about 118°. All attempts to convert it into 3-nitro-*N*-methylcarbazole were unsuccessful. F. A. M.

Cyclic bis-Imines and their Decomposition. IV. J. VON BRAUN and J. POHL (*Ber.*, 1924, **57**, [*B*], 480—484).—Coniine (2 mols.) and αε-dibromopentane interact at water-bath temperatures to give a solid product, probably in accordance with the equation: $2C_8H_{16}>NH+Br[CH_2]_5Br=C_8H_{16}>N\cdot HBr+C_8H_{16}N[CH_2]_5Br$. On further warming there results the hygroscopic quaternary *bromide*, $C_{13}H_{26}NBr$ (I), m. p. 228°. The latter, when heated with ammonia at 200°, is partly converted into the *bis-imine* (II), a colourless oil, b. p. 145—146°/11 mm., d_4^{18} 0·89.



$$CH_2<\begin{matrix}CH_2\cdot CHPr\\CH_2\cdot CH_2\end{matrix}>\underset{Br}{N}<\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}>CH_2$$

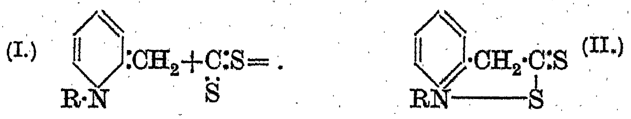
(I.)

$$CH_2<\begin{matrix}CH_2\cdot CHPr\cdot NH\cdot CH_2\cdot CH_2\\CH_2\text{-}CH_2\text{-}NH\text{-}CH_2\text{-}CH_2\end{matrix}>CH_2$$

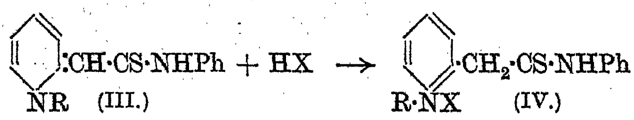
(II.)

The *picrate*, *hydrochloride*, and *chloroplatinate* are oily. The *dimethiodide* yields a solid *chloroplatinate*, m. p. 248°. A 40-g. frog is completely paralysed by 0·005 g. of the bis-imine in 3—4 minutes, whilst the same dose of coniine requires about 39 minutes to produce paralysis. F. A. M.

Reactions of *N*-Alkyl-methylenedihydro-pyridines and -quinolines. W. SCHNEIDER, K. GAERTNER, and A. JORDAN (*Ber.*, 1924, **57**, [*B*], 522—532; cf., A. 1921, i, 878).—*N*-Alkyl-α-(or γ-)methylenepyridanes (cf. Decker, A., 1905, i, 667), which are formed on treating quaternary salts of α- or γ-methylated pyridines or quinolines with alkali, are capable of combining directly with either carbon disulphide, phenylcarbimide, or phenylthiocarbimide to form crystalline products. In the case of α-picoline alkiodides, it is suggested that the methylene base (I) reacts thus:



so that the product (II) would be the betaine of *N*-alkyl-α-pyridyldithioacetic acid; whilst the thiocarbimide additive product of the methylene base would have the structure (III) and its salts the



structure (IV), the carbimide additive compounds having analogous formulæ which would agree with the ready oxidation of both sulphur and oxygen compounds by cold neutral permanganate, whilst in acid solution they are only slowly oxidised.

N-Methyl-α-methylenedihydropyridine was prepared by treating α-picoline methosulphate with alkali and extracting with ether; on treating the yellow ethereal solution with carbon disulphide, yellow leaflets of the *additive* compound, $C_8H_9NS_2$, were formed which charred at 175° and had m. p. 186°. The *phenylthiocarbimide* (III) forms dark red crystals, m. p. 153°. It is soluble in dilute acids to give pale yellow solutions of the salts (IV), from which the compound is reprecipitated by alkalis. The *hydriodide* forms colourless needles, m. p. 160°, the *picrate*, yellow needles, m. p. 156°. The *phenylcarbimide* forms yellow needles, m. p. 172° (*picrate*, yellow needles, m. p. 173°). N-*Ethyl-α-methylenedihydropyridine* gave the following derivatives: *carbon disulphide additive* compound, yellow leaflets, char at 170°, m. p. 180°; *phenylthiocarbimide*, dark red crystals, m. p. 143°; *hydriodide*, m. p. 177°, *picrate*, m. p. 113°; *phenylcarbimide*, needles, m. p. 172°. N-*Benzyl-α-methylenedihydropyridine* (from α-picoline benzochloride) gave the following derivatives: *phenylthiocarbimide*, red crystals, m. p. 189°; *picrate*, m. p. 150°; *phenylcarbimide*, yellow crystals, m. p. 192°; *picrate*, m. p. 126°. The following are derivatives of *methylene-anhydro bases from* s-*collidine alkiodides:* (i) *methiodide*: *phenylthiocarbimide*, yellowish-brown crystals, m. p. 185°; *phenylcarbimide*, yellow, m. p. 188°; (ii) *ethiodide*: *phenylthiocarbimide* compound, yellowish-brown, m. p. 190°; *phenylcarbimide*, bright yellow, m. p. 198°. The following derivatives of N-*methyl-γ-methylenedihydropyridine* (from γ-picoline methiodide) are described: *phenylthiocarbimide*, brown leaflets, m. p. 218°; *phenylcarbimide*, yellow needles, m. p. 196°. The *pseudo*-bases from pyridine methiodide and from β-picoline methiodide gave no recognisable crystalline products with either phenylcarbimide or thiocarbimide. N-*Methyl-α-methylenedihydroquinoline* with carbon disulphide gave no definite product but the following are described: *phenylthiocarbimide*, coppery leaflets, m. p. 170°; *hydriodide*, pale yellow, m. p. 192°; *perchlorate*, yellowish-brown, m. p. 188—190°; *picrate*, yellow, m. p. 168—169°; *phenylcarbimide*, yellow crystals, m. p. 173°; *hydriodide*, yellow, m. p. 190—191°; *perchlorate*, colourless, m. p. 199°; *picrate*, m. p. 168—169°. Derivatives of N-*ethyl-α-methylenedihydroquinoline* are: *phenylthiocarbimide*, reddish-brown crystals, m. p. 162°; *phenylcarbimide*, yellow needles, m. p. 167°. Derivatives of *methylene-anhydro base from α:γ-dimethylquinoline ethiodide* are: *phenylthiocarbimide*, reddish-brown needles, m. p. 145°; *phenylcarbimide*, yellow needles, m. p. 207°. Crystalline *additive* compounds were also obtained from the base derived from lepidine ethiodide, but were not examined further. Experiments were carried out also with the *pseudo*-bases derived from 2-ethylquinoline ethiodide, 4-ethylquinoline ethiodide, α-*iso*propylquinoline ethiodide, and quinoline ethiodide itself, but no crystalline additive compounds could be obtained.

F. A. M.

Arylated Pyridines. IV. *N*-Alkylquinopyridanes. W. Dilthey, C. Ammon, and A. Ebert (*J. pr. Chem.*, 1924, [ii], **107**, 7—15; cf. A., 1921, i, 735; 1922, i, 272).—The arylated quinopyridanes obtained by the action of ammonia on the *N*-arylpyridinium salts formed from primary amines and *p*-hydroxylarylpyrylium salts are considered to possess a quinoid structure in the yellowish-red anhydro bases and a benzenoid structure in their bright yellow salts and hydrates. The additive compounds of the bases with benzene are also assigned a quinoid structure. The following individual compounds are described: 1 : 2 : 6-*triphenyl*-4-p-*hydroxyphenylpyridinium chloride*, $C_{29}H_{22}ONCl,0\cdot5HCl$, bright yellow crystals, m. p. 335°, was obtained from 2 : 6-diphenyl-4-*p*-hydroxyphenylpyrylium chloride and aniline (cf. A., 1922, i, 272), and on heating in a xylene bath this gives the dark yellow, neutral *chloride*, $C_{29}H_{22}ONCl$. The two chlorides behave very differently with alcoholic ammonia. The hydrochloride yields a very stable meriquinoid *salt*, $C_{58}H_{43}O_2N_2Cl$, m. p. about 295—300°, from which chlorine is removed quantitatively only by boiling with silver hydroxide. The neutral chloride, in the same way, is converted into a *dihydrate* of the anhydro base, 1 : 2 : 6-*triphenyl*-4-*quino*-1 : 4-*dihydropyridine*. The dihydrate, yellow plates, darkens at 120—130°, melting twice between this temperature and 263°. When dehydrated, the dihydrate affords the orange monohydrate, from which the dark red anhydro base (yellow *picrate* and *nitrate*) is obtained, this, when heated, behaving similarly to the dihydrate, melting first at 175° and then, after solidifying, at 263° to a dark red fluid. With benzene, an *additive* compound, $C_{29}H_{21}ON,C_6H_6$ is formed, as fine, red needles, these, on heating at 110°, giving the anhydro base. Similarly, 2 : 6-diphenyl-4-*p*-hydroxyphenylpyrylium chloride, on heating with *p*-toluidine, gives 2 : 6-*diphenyl*-4-p-*hydroxyphenyl*-1-p-*tolylpyridinium chloride*, bright yellow plates (+$2H_2O$; the water is lost at 100—130°, giving the anhydrous compound, m. p. 343—345°). The *nitrate* is yellow, m. p. 168° (decomp.). With alcoholic ammonia, the chloride yields a *dihydrate* of the anhydro base, yellowish-red needles, which lose their water at 100—130°, giving the anhydro base, 2 : 6-*diphenyl*-1-p-*tolyl*-4-*quino*-1 : 4-*dihydropyridine*, reddish-violet, m. p. 293°. The anhydro base forms an insoluble *additive* compound with benzene, $C_{30}H_{23}ON,C_6H_6$.

From the reaction product of 4 : 6-diphenyl-2-*p*-hydroxyphenylpyrylium iodide and β-naphthylamine in benzene solution, the *picrate*, yellow, m. p. 162—163°, and *perchlorate*, yellow, m. p. 177—178°, of 4 : 6-diphenyl-2-*p*-hydroxyphenyl-1-β-naphthylpyridine were isolated. R. B.

5 : 6 : 7 : 8-Tetrahydroquinolines and their Derivatives. IV. J. von Braun, W. Gmelin, and A. Petzold (*Ber.*, 1924, **57**, [*B*], 382—391; cf. von Braun, Gmelin, and Schultheiss, A., 1923, i, 835).—Further examples are cited which confirm the previous conclusion that the presence of alkyl substituents, according to their number and weight, in the pyridine half of the quinoline molecule inhibits to a greater or less extent the introduction of hydrogen atoms in the presence of nickel into the 1 : 2 : 3 : 4-positions and favours the production of 5 : 6 : 7 : 8-derivatives. The maximum effect is observed in the case of 2 : 3 : 4-trimethylquinoline, which, in complete contrast to quinoline itself, is hydrogenated exclusively in the benzenoid nucleus. The introduction of alkyl groups into the 5 : 6 : 7 : 8-positions exerts an opposite effect. The observations are explained by the hypothesis that the quinoline derivatives are equilibrium mixtures of two forms (benzenoid and centric structures alternating in each nucleus); in extreme cases of loading with substituents, only one variety is present.

2-Propylquinoline dissolved in decahydronaphthalene is converted by hydrogen in the presence of nickel at 170° into a mixture of 2-*propyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (65%) and 2-*propyl*-5 : 6 : 7 : 8-*tetrahydroquinoline* (35%). The former compound is a colourless liquid, b. p. 140—141°/10 mm. (*hydrochloride*, m. p. 221°; *benzoyl* derivative, microscopic crystals, m. p. 101°), whereas the latter base is a colourless liquid with a pronounced odour of pyridine, b. p. 130—132°/11 mm. (the non-crystalline *hydrochloride*, the *chloroplatinate*, decomp. 62°, and the *picrate*, yellow needles, m. p. 119°, are described). 2-*Propyldecahydroquinoline*, obtained in almost quantitative yield by the reduction of 2-propyl-5 : 6 : 7 : 8-tetrahydroquinoline with sodium and alcohol, has b. p. 123—125°/20 mm.; it somewhat resembles coniine in physiological activity. It yields a non-crystalline *nitroso* derivative, an extremely hygroscopic *hydrochloride*, and a *picrate*, m. p. 134—135°.

4-Phenyl-2-methylquinoline gives 4-phenyl-2-methyl-1 : 2 : 3 : 4-tetrahydroquinoline, m. p. 66—67° (16%), and 4-*phenyl*-2-*methyl*-5 : 6 : 7 : 8-*tetrahydroquinoline*, a viscous liquid, b. p. 181—183°/13 mm. (84%). The latter compound yields a *picrate*, m. p. 186—187°, a non-crystalline *hydrochloride*, and a yellow *chloroplatinate*, decomp. 145—147°.

2 : 3 : 4-Trimethylquinoline, m. p. 92° (65° is recorded in the literature), is prepared in the usual manner from aniline and methylacetylacetone; the *picrate*, m. p. 216°, *hydrochloride*, m. p. 274°, and lemon-yellow *methiodide*, m. p. 260°, are described. When hydrogenated in the presence of nickel at 155—160°, the base yields about 2% of 2 : 3 : 4-trimethyl-1 : 2 : 3 : 4-tetrahydroquinoline, which is identified as the *chloroplatinate* of the corresponding *methochloride*, $C_{25}N_{41}Cl_2N_6Pt$, lustrous, orange-coloured needles, m. p. 176°. The main product of the reduction is 2 : 3 : 4-*trimethyl*-5 : 6 : 7 : 8-*tetrahydroquinoline*, a liquid with an odour resembling that of pyridine, b. p. 145—147°/13 mm., which yields a crystalline *dihydrate*, m. p. 31—32°; the *picrate*, m. p. 147°, *hydrochloride*, m. p. 174°, and *methiodide*, m. p. 125—126°, are described. The base is reduced by sodium and alcohol to 2 : 3 : 4-*trimethyldecahydroquinoline*, a colourless liquid with a pronounced odour of hemlock, b. p. 115°/13 mm.; the non-crystalline *nitroso* derivative, the *hydrochloride*, and the *product*, $C_{14}H_{25}NI$ (obtained by exhaustive methylation), a crystalline powder, m. p. 227° after softening at 218°, are described.

2 : 6-Dimethylquinoline readily undergoes catalytic hydrogenation at 105°, yielding 2 : 6-dimethyl-5 : 6 : 7 : 8-tetrahydroquinoline (1·5%) (*picrate*, m. p. 127°; *chloroplatinate*, $C_{22}H_{32}N_2Cl_6Pt$, an orange-coloured powder, decomp. 185°), and 2 : 6-dimethyl-1 : 3 : 2 : 4-tetrahydroquinoline (98·5%), b. p. 133°/12 mm., m. p. 32° (*benzoyl* derivative), m. p. 103°.

Acetylacetone and *p*-xylidine readily yield the corresponding *xylidide*, $C_{13}H_{17}ON$, b. p. about 170°/12 mm., m. p. 41°, which with concentrated sulphuric acid gives 2 : 4 : 5 : 8-*tetramethylquinoline*, a pale yellow, crystalline mass, m. p. 48°, b. p. 168—172°/12 mm.; the base exhibits a pronounced, bluish-violet fluorescence in acid solution. The *hydrochloride*, m. p. 254° after sintering at 243°, and the *picrate*, small needles, m. p. 161°, are described; the methiodide could not be obtained. The base is hydrogenated at 160—170° to a mixture of 2 : 4 : 5 : 8-*tetramethyl*-5 : 6 : 7 : 8-*tetrahydroquinoline* (4%), a colourless liquid, b. p. 135—137°/12 mm. (the non-crystalline *hydrochloride*, the *chloroplatinate*, coarse crystals which blacken above 196°, and the *picrate*, m. p. 131°, are described), and 2 : 4 : 5 : 8-*tetramethyl*-1 : 2 : 3 : 4-*tetrahydroquinoline* (96%), b. p. 143—145°/12 mm. (the non-crystalline *benzoyl* derivative, the *hydrochloride*, m. p. 211°, and the *picrate*, m. p. 160°, are described).

[With K. Müncker.]—Tetrahydro-α-naphthylamine reacts readily with acetylacetone to yield the *compound* $C_{10}H_{11}N{:}CMe{\cdot}CH_2{\cdot}Ac$, a viscous liquid, b. p. 208°/15 mm., which with concentrated sulphuric acid gives 2 : 4-*dimethyl*-7 : 8 : 9 : 10-*tetrahydro-α-naphthaquinoline*, b. p. 196—200°/15 mm., m. p. 49° (*hydrochloride*, m. p. 243°; *picrate*, m. p. 201°; *methiodide*, m. p. 254°). The catalytic hydrogenation of the base proceeds with unusual difficulty; even at temperatures above 200° the action stops prematurely, owing to poisoning of the catalyst. The main product is 2 : 4-*dimethyl*-1 : 2 : 3 : 4 : 7 : 8 : 9 : 10-*octahydro-α-naphthaquinoline*, a viscous liquid, b. p. 190°/16 mm. (*benzoyl* derivative, m. p. 130—131°; *nitroso* compound, m. p. 62°; *hydrochloride*, m. p. 204°; *picrate*, m. p. 130°). The portion of the product which does not react with benzoyl chloride appears to have suffered partial hydrogenation in the central nucleus. The catalytic reduction of 2 : 4-dimethyl-α-naphthaquinoline, m. p. 52°, yields a mixture of unchanged base, 2 : 4-dimethyl-7 : 8 : 9 : 10-tetrahydro-α-naphthaquinoline, and the above octahydro base; the primary change occurs at the extreme benzene nucleus. H. W.

Intramolecular Condensation Reactions of Aminoacetals and Aminoaldehydes. I. Synthesis of Dihydroquinoline and certain Homologues. C. Räth (*Ber.*, 1924, 57, [*B*], 550—555).—If chloro- or bromo-acetal is heated with *o*-toluidine in a closed tube at 260°, 1 : 2-*dihydroquinoline* (90% yield) is obtained as an almost colourless liquid, b. p. 226° (*hydrochloride*, white, crystalline powder, m. p. 214°; *picrate*, yellow, crystalline powder, m. p. 199—200°; *nitroso* derivative, a viscous, yellow oil), and is accompanied by small quantities of the intermediately formed o-*toluidine*-N-*monoacetal*, a viscous substance, b. p. 250—262°. On heating 1 : 2-dihydroquinoline with ethylene chlorohydrin in benzene solution, 1-(β-*hydroxyethyl*)-1 : 2-*dihydroquinoline* is formed as a viscous, pinkish liquid, b. p. 166—168°/11 mm. The *hydrochloride, picrate*, and *methiodide* were obtained only as oils.

In a similar way, β-bromopropionacetal condenses with *o*-toluidine to form 1 : 2-*dihydroquinaldine*, which is a faintly yellow liquid (b. p. 234—240°) affording an oily *nitroso* derivative; the *hydrochloride*, a white, crystalline powder, has m. p. 197—198°; the *picrate*, yellow crystals, m. p. 189—190°. If methyl-*o*-toluidine be used in place of *o*-toluidine, the product is 1-methyl-1 : 2-dihydroquinaldine, b. p. 252—260° (Freund, A., 1906, i, 600; 1909, i, 417); the *hydrochloride* is an oil, the *picrate* yellow rosettes, m. p. 148—150°. As a by-product was obtained α-o-*tolylmethylaminopropaldehyde*, $CH_3\cdot C_6H_4\cdot NMe\cdot CHMe\cdot CHO$, b. p. 283—288°, which forms a *picrate*, m. p. 152—153°. F. A. M.

The Reactivity of the Chlorine Atom in the 2-Position in Quinoline and Quinoline Derivatives. J. TRÖGER and H. MEINECKE (*J. pr. Chem.*, 1923, [ii], **106**, 203—225).—2-Chloroquinoline reacts slowly with sodium benzenesulphinate in presence of alcohol to give 2-*benzenesulphonylquinoline*, colourless needles, m. p. 160°. This compound is unaffected by a short fusion with alkali, prolonged fusion effecting profound decomposition. When heated with dilute hydrochloric acid at 235°, it affords carbostyril, benzenesulphinic acid, and benzene disulphoxide. It forms no double salts. 2-Chloroquinoline does not react with alkali derivatives of thiophenols, but 2-chloro-3-benzenesulphonylquinoline and the sodium derivative of *p*-thioltoluene afford 3-*benzenesulphonylcarbostyril* p-*tolyl thioether*, $C_9H_5N(SO_2Ph)(SC_7H_7)$, colourless needles, m. p. 131° with previous sintering. When 2-chloro-3-benzenesulphonylquinoline is heated in alcoholic solution with sodium benzenesulphinate at 130°, 2 : 3-dibenzenesulphonylquinoline (m. p. 204°) results (cf. A., 1923, i, 368).

2-o-*Toluenesulphonylquinoline* (colourless prisms, m. p. 127°) was prepared by the above method. 2-*Amino*-3-o-*toluenesulphonylquinoline* (from *o*-toluenesulphonylacetonitrile and *o*-aminobenzaldehyde), white prisms, m. p. 179·5° (*hydrochloride*,

$$C_{16}H_{14}O_2N_2S,HCl,H_2O,$$

white crystals), is converted by nitrous acid into 3-o-*toluenesulphonylcarbostyril*, yellow prisms, m. p. 270°, this substance, with phosphorus pentachloride, affording 2-*chloro*-3-o-*toluenesulphonylquinoline*, colourless needles, m. p. 161°.

From the last-named chloro compound, 3-o-*toluenesulphonylcarbostyril* p-*tolyl thioether* (white crystals, m. p. 191°), 3-o-*toluenesulphonyl*-2-*benzenesulphonylquinoline* (colourless prisms, m. p. 260°), and 3-o-*toluenesulphonylcarbostyril phenyl thioether* (colourless needles, m. p. 154°) were obtained. The last-named ether, on oxidation, affords 3-*o*-toluenesulphonylcarbostyril.

Sodium *p*-toluenesulphinate reacts less rapidly than the benzenesulphinate with 2-chloroquinoline, 2-p-*toluenesulphonylquinoline* (white crystals, m. p. 141°) resulting. Other compounds in this series are: 3-p-*toluenesulphonylcarbostyril* p-*tolyl thioether*, colourless crystals, m. p. 195°; 3-p-*toluenesulphonyl*-2-p-*toluenesulphonylquinoline*, colourless needles, m. p. 184—185°; and 3-p-*toluenesulphonylthiocarbostyril*, lemon-yellow powder, m. p. 226°.

2-p-*Chlorobenzenesulphonylquinoline* forms white needles, m. p. 190°; 3-p-*chlorobenzenesulphonylcarbostyril phenyl thioether* (yellow needles, m. p. 149°) is formed together with some 3-*p*-chlorobenzenesulphonylcarbostyril when 2-chloro-3-*p*-chlorobenzenesulphonylquinoline reacts with sodium thiophenoxide, and on oxidation affords 3-p-*chlorobenzenesulphonyl*-2-*benzenesulphonylquinoline*, white crystals, m. p. 264° (sintering at 250°).

3-p-*Chlorobenzenesulphonylcarbostyril* p-*tolyl thioether*, colourless needles, m. p. 147°, cannot be oxidised to the corresponding disulphone. 2-p-*Bromobenzenesulphonylquinoline* forms white needles, m. p. 145°. 2-*Amino*-3-p-*bromobenzenesulphonylquinoline*, lemon-yellow needles, m. p. 223°, forms a *hydrochloride*, needles, m. p. 256° (decomp.), *nitrate*, yellow, crystalline powder, m. p. (indef.) 105—224°, and *chloroplatinate*, yellowish-red crystals, and is converted by nitrous acid into 3-p-*bromobenzenesulphonylcarbostyril*, yellow needles, m. p. 269°. The last-named substance is converted by phosphorus pentachloride into 2-*chloro*-3-p-*bromobenzenesulphonylquinoline*, colourless needles, m. p. 181·5°. The following were also prepared: 3-p-*bromobenzenesulphonylcarbostyril ethyl ether*, colourless needles, m. p. 156°; 3-p-*bromobenzenesulphonylthiocarbostyril*, yellow crystals, m. p. 254°, and 3-p-*bromobenzenesulphonylcarbostyril* p-*tolyl thioether*, white needles, m. p. 159°.

2-β-*Naphthalenesulphonylquinoline* forms colourless stars, m. p. 137°. 2-*Amino*-3-β-*naphthalenesulphonylquinoline*, yellow needles, has m. p. 180° and forms a *hydrochloride*, yellow needles, m. p. 250° (with previous decomp.), and a *nitrate*, white needles. 3-β-*Naphthalenesulphonylcarbostyril* forms yellow needles, m. p. 294°; 2-*chloro*-3-β-*naphthalenesulphonylquinoline*, yellow crystals, has m. p. 159°; 3-β-*naphthalenesulphonylcarbostyril ethyl ether* forms yellow needles, m. p. 121°; 3-β-*naphthalenesulphonylcarbostyril* p-*tolyl thioether*, silver crystals, has m. p. 176° and oxidises irregularly.

2-o-*Anisolesulphonylquinoline* forms rhombs, m. p. 134°. 2-*Amino*-3-o-*anisolesulphonylquinoline*, colourless crystals, has m. p. 239°, and was converted into 3-o-*anisolesulphonylcarbostyril*, yellow crystals, m. p. 250°. 2-*Chloro*-3-o-*anisolesulphonylquinoline*, quadratic crystals, m. p. 171°, was converted into 3-o-*anisolesulphonylcarbostyril phenyl thioether*, colourless rhombohedra, m. p. 160°, and into 3-o-*anisolesulphonylthiocarbostyril*, yellow crystals, m. p. 233° (*methyl* ether, colourless crystals, m. p. 150°).

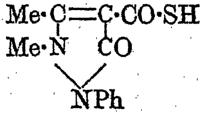
2-p-*Phenetolesulphonylquinoline*, white leaflets, has m. p. 133·5°. 2-*Amino*-3-p-*phenetolesulphonylquinoline* forms yellow leaflets, m. p. 178° [*hydrochloride*, needles, m. p. 233° (decomp.)], and was converted into 3-p-*phenetolesulphonylcarbostyril*, yellow needles, m. p. 241°. 2-*Chloro*-3-p-*phenetolesulphonylquinoline*, yellow crystals, m. p. 162°, was converted into 3-p-*phenetolesulphonylcarbostyril* p-*tolyl thioether*, colourless needles, m. p. 141°, the last-named substance affording, on oxidation, 3-p-*phenetolesulphonyl*-2-p-*toluenesulphonylquinoline*, needles, m. p. 249° (sintering at 239°). 3-p-*Phenetolesulphonylthiocarbostyril*, yellow needles, has m. p. 142°.

From the above it is seen that in 2-chloroquinoline, the chlorine atom cannot be displaced by the ·SR radical, whereas the presence of the grouping $\cdot SO_2R$ in position 3 (especially if R is a *p*-tolyl radical) facilitates the displacement. Again, whilst 2-amino-β-arylsulphonylquinolines (monoacidic bases) cannot be diazotised, the amino radical can readily be displaced by hydroxyl, using nitrous acid. E. E. T.

Carbithionic and Thionic Acid Derivatives of Pyrazolones. E. BENARY and A. SCHMIDT (*Ber.*, 1924, 57, [*B*], 517—522).—By the action of chlorocarbonic ester, or ethyl bromide, on antipyrine in carbon disulphide solution, a product is obtained according to the equation :

$$C_{11}H_{11}ON_2+EtBr+CS_2=C_{11}H_{11}ON_2\cdot CS\cdot SEt+HBr.$$

Since the new substance does not give the typical nitroso reaction of antipyrine, it is assumed that the group –CS·SEt has occupied position 4 and that the substance is *ethyl* 1-*phenyl*-2 : 3-*dimethylpyrazolone*-5-*carbithionate* (cf. Houben, A., 1906, i, 847). It forms orange leaflets, m. p. 178·5—179°, gives no nitroso compound with nitrous acid, and forms an intense red precipitate with bromine in chloroform solution. When treated with alcoholic potassium hydroxide, it affords ethyl mercaptan and 1-*phenyl*-2 : 3-*dimethylpyrazolone*-5-*thionic acid*, sulphur-yellow needles, m. p. 81—82° (annexed formula) (*potassium* and *silver* salts described). The *methyl* ester, yellow needles ($+1\cdot5H_2O$) has m. p. 95° (anhydrous ester, m. p. 113—114°). The following were made in a similar manner from the appropriate substance, ethyl bromide, and aluminium chloride in carbon disulphide solution.



Ethyl 1-*phenyl*-3-*methyl*-5-*pyrazolone*-4-*carbithionate*, from 1-methyl-3-phenyl-5-pyrazolone, forms greenish-yellow prisms, m. p. 81—82°. *Ethyl* 3-*methyl*-5-*pyrazolone*-4-*carbithionate*, orange prisms or needles, m. p. 186°, which with alkali yields 3-methyl-5-pyrazolone; on treating the alkaline solution from the hydrolysis with methyl sulphate, white or pale yellow needles (m. p. 115·5°) are formed, of *methyl* 1 : 2 : 3-(or 1 : 2 : 5-)*trimethyl*-5-*pyrazolone*-4-*carbithionate*. *Ethyl* 5-*pyrazolone*-4-*carbithionate*, from 5-pyrazolone, forms reddish-brown prisms, m. p. 184—185°. *Ethyl* 1-*phenyl*-5-*methyl*-3-*pyrazolone*-4-*carbithionate* forms orange-yellow leaflets, m. p. 114°. From thiopyrine a yellow, crystalline *substance*, m. p. 166°, probably the corresponding carbithionic acid, was obtained. F. A. M.

Dipyridyls from Pyridine. C. R. SMITH (*J. Amer. Chem. Soc.*, 1924, 46, 414—419).—The author describes the preparation and separation of 2 : 2-, 3 : 3-, 3 : 4-, and 4 : 4-dipyridyls. 3 : 4-*Dipyridyl* (plates, m. p. 61°, b. p. 297°) forms a *dihydrochloride*, *mercurichloride,* and *chloroplatinate* and is distinguished from its isomerides by certain colour reactions. On oxidation with potassium permanganate, it affords nicotinic and *iso*nicotinic acids. In the interaction of sodium and pyridine in presence of dry oxygen, the proportions of the various isomerides produced depend on the time, temperature, and pressure conditions. A. B. S.

The Constitution of the Products arising from the Condensation of o-Aminoazo Compounds with Aldehydes. II. OTTO FISCHER (*J. pr. Chem.*, 1924, [ii], **107**, 16—49; cf. A., 1922, i, 956).—A further series of *N*-substituted iminazoles, some already known, has been obtained by the condensation of *o*-aminoazo compounds with aldehydes, and the reduction of these with hydriodic acid is described, the products being a benziminazole and an amine. The condensation products of chrysoidine and aldehydes are shown to be derivatives of 1-anilino-2-phenyl-5-aminobenziminazole. The action of benzyl chloride on *o*-aminoazo compounds did not give the expected *N*-aryldihydrobenziminazoles, but their decomposition products, *e.g.*, aniline and 2-phenylnaphthiminazole. If the benzyl group is introduced into the amine prior to coupling, the azo dyes formed easily decompose in a similar way.

[With E. THIEL.]—From benzeneazo-β-naphthylamine, the following compounds have been prepared. With acetaldehyde, 1-anilino-2-methylnaphthiminazole [yellow *picrate,* m. p. 234°; yellow *nitrosoamine,* decomp. 124°; *acetyl* compound, m. p. 230° (decomp.)]. With methyl iodide in benzene solution it gives a *methyl* base, lustrous, colourless plates, m. p. 195° (*hydrochloride,* m. p. 250°), which does not form a nitrosoamine. With *o*-chlorbenzaldehyde, 1-*anilino*-2-o-*chlorphenylnaphthiminazole,* colourless, tufted needles, m. p. 231° [*picrate,* m. p. 192° (decomp.)]. With salicylaldehyde, 1-*o*-hydroxyanilino-2-phenylnaphthiminazole [golden-yellow *nitrosoamine, diacetyl* compound, m. p. 169° (decomp.)], an intermediate compound, violet-tinged needles, $C_{23}H_{17}ON_3$, being isolated which goes over into the colourless iminazole at 100—110°. With *p*-hydroxybenzaldehyde, 1-*anilino*-2-p-*hydroxyphenylnaphthiminazole,* colourless crystals, m. p. 233° (decomp.) (*nitrosoamine,* decomp. 200°, *diacetyl* compound, prisms, m. p. 224°).

[With F. STAUBER and W. HILD.]—When heated with hydriodic acid (*d* 1·7) under pressure, the *N*-arylbenziminazoles and naphthiminazoles are converted into the corresponding primary amine and iminazole. The iminazoles are not further decomposed even at 180—200°. The following compounds have been prepared.

From *o*-aminoazo-*p*-toluene and benzaldehyde, 1-*p*-toluidino-2-phenyl-5-methylbenziminazole, which on reduction yields *p*-toluidine and 2-*phenyl*-5-*methylbenziminazole,* dense white crystals, m. p. 240°. Similarly, *o*-chlorobenzaldehyde yields 1-p-*toluidino*-2-o-*chlorophenyl*-5-*methylbenziminazole,* white, monoclinic needles, m. p. 195° (*picrate,* m. p. 178—179°, *nitrosoamine,* decomp. 124°), which is reduced to *p*-toluidine and 2-o-*chlorophenyl*-5-*methylbenziminazole,* white needles, m. p. 160° (*picrate,* decomp. 189°). From *m*-nitrobenzaldehyde is similarly obtained 1-*p*-toluidino-2-*m*-nitrophenyl-5-

methylbenziminazole, greyish-yellow needles, decomp. 224—225° (*picrate*, decomp. 174°; *nitrosoamine*, decomp. 120°), and on reduction, *p*-toluidine and 2-m-*aminophenyl-5-methylbenziminazole*, white, crystalline plates, m. p. 236°. With *o*-nitrobenzaldehyde, 1-*p*-toluidino-2-*o*-nitrophenyl-5-methylbenziminazole (*picrate*, decomp. 182°; *nitrosoamine*, decomp. 130°) and 2-o-*aminophenyl-5-methylbenziminazole*, white needles, m. p. 190°; and with *p*-nitrobenzaldehyde, 1-*p*-toluidino-2-*p*-nitrophenyl-5-methylbenziminazole and 2-p-*aminophenyl-5-methylbenziminazole*, white plates, m. p. 124°, containing water of crystallisation. This base, when diazotised and coupled with β-naphthol in alcohol–pyridine solution, gives a reddish-brown azo dye, m. p. 330°. From *o*-aminoazo-*p*-toluene and *p*-dimethylaminobenzaldehyde, 1-p-*toluidino-2-dimethylaminophenyl-5-methylbenziminazole*, white needles, m. p. 249° (*picrate*, m. p. 177°; *nitrosoamine*, decomp. 85°), is obtained, which on reduction yields *p*-toluidine and the iminazole, m. p. 124°, obtained in the reduction of the base from *p*-nitrobenzaldehyde.

Benzeneazo-β-naphthylamine and benzaldehyde yield 1-anilino-2-phenylnaphthiminazole, which on reduction yields 2-phenylnaphthiminazole, m. p. 217—218°. The reduction of the condensation products of substituted benzaldehydes and benzeneazo-β-naphthylamine yields the same phenylnaphthiminazole. From *p*-hydroxybenzeneazo-β-naphthylamine (*diacetyl* derivative, m. p. 184°, *dibenzoyl* derivative, m. p. 199°) the following compounds were obtained: with benzaldehyde in alcoholic solution, 1-p-*hydroxyanilino-2-phenylnaphthiminazole*, white needles, m. p. 183° (*nitrosoamine*, decomp. 135°), which on reduction yields *p*-aminophenol and 2-phenylnaphthiminazole; with *o*-chlorobenzaldehyde, 1-p-*hydroxyanilino*-2-o-*chlorophenylnaphthiminazole*, white needles, m. p. 198° (*nitrosoamine*, decomp. 110°), and on reduction *p*-aminophenol and 2-o-*chlorophenylnaphthiminazole*, white needles, m. p. 214°; with salicylaldehyde in methyl-alcoholic solution, 1-p-*hydroxyanilino*-2-o-*hydroxyphenylnaphthiminazole*, white needles, m. p. 276°, which on reduction yields 2-o-*hydroxyphenylnaphthiminazole*, white needles, m. p. 280°; with furfuraldehyde, 1-p-*hydroxyanilino-2-furylnaphthiminazole*, white needles, m. p. 195° (*picrate*, yellow powder, *nitrosoamine*, yellow, easily decomp.). In contrast to the foregoing substituted iminazoles, which are very stable to most reducing agents, 1-p-*nitroanilino*-2-o-*chlorophenylnaphthiminazole*, bright yellow crystals, m. p. 283° (*nitrosoamine*, decomp. 105—107°), prepared from *p*-nitroanilinoazo-β-naphthylamine and *o*-chlorobenzaldehyde in acetic acid solution, yields *p*-phenylenediamine and 2-*o*-chlorophenylnaphthiminazole on reduction with zinc and acetic acid.

[With G. Seufert and H. Hojer.]—The azo dye obtained from diazotised anthranilic acid and β-naphthylamine forms crimson-red needles, m. p. 182—183°; it gives, with benzaldehyde, 1-o-*carboxyanilino-2-phenylnaphthiminazole*, colourless, monoclinic prisms, m. p. 263—264°, decomp., which on nitration in acetic acid yields 1-o-*carboxy*-p-*nitroanilino-2-phenylnaphthiminazole*, bright yellow pyramids, m. p. 274°, and this on reduction with hydriodic acid gives

2-phenylnaphthiminazole. With acetaldehyde, the same dye yields 1-o-*carboxyanilino-2-methylnaphthiminazole*, colourless, monoclinic plates, m. p. 283° (after slight decomp. at 260°), which gives 2-methylnaphthiminazole, m. p. 168° (*picrate*, m. p. 242°), on reduction.

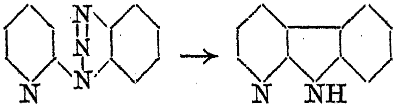
1-m-*Carboxybenzeneazo*-β-*naphthylamine*, yellowish-red needles, m. p. 220°, gives condensation products with aldehydes which are distinguished by their insolubility in solvents. The following compounds were prepared. From acetaldehyde, 1-m-*carboxyanilino*-2-*methylnaphthiminazole*, white, crystalline powder, m. p. 276°; from furfuraldehyde, 1-m-*carboxyanilino*-2-*furylnaphthiminazole*, m. p. 273—274°; from salicylaldehyde, 1-m-*carboxyanilino*-2-o-*hydroxyphenylnaphthiminazole*, colourless granules, m. p. 232° (*nitrosoamine*, decomp. 110°).

p-Carboxybenzeneazo-β-naphthylamine crystallises from benzene–alcohol in crimson-red needles, m. p. 263—264°; it condenses with aldehydes in alcoholic solution in the presence of pyridine or acetic acid. The following compounds were obtained. From benzaldehyde, 1-p-*carboxyanilino-2-phenylnaphthiminazole*, colourless prisms, m. p. 255° (decomp.) [*picrate*, m. p. 205° (decomp.), *acetyl* derivative, m. p. 218°, *nitrosoamine*, decomp. 213—214°], which on reduction yields 2-phenylnaphthiminazole and *p*-aminobenzoic acid. On nitration, the original base gives 1(2 : 4-*dinitroanilino*)-2-*phenylnaphthiminazole*, small, yellow plates, decomp. 270—272°. The dinitro compound with hydriodic acid gives 2-phenylnaphthiminazole and 1 : 2 : 4-triaminobenzene. With acetaldehyde, the azo dye gives 1-p-*carboxyanilino-2-methylnaphthiminazole*, white plates, m. p. 287° (*dinitro* derivative, m. p. 235°, yielding 2-methylnaphthiminazole on reduction). With furfuraldehyde, 1-p-*carboxyanilino*-2-*furylnaphthiminazole*, colourless prisms, m. p. 251° (greenish-yellow *nitrosoamine*).

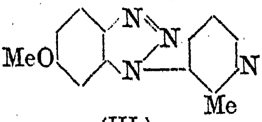
[With F. VON MANN-SIECHLER.]—The base, $C_{19}H_{16}N_4$, colourless, white plates, m. p. 228°, obtained by the action of benzaldehyde on chrysoidine (*cf.* A., 1898, i, 155) gives a *diacetyl* derivative, m. p. 105° (decomp.), a *picrate*, decomp. 204°, a *picrolonate*, decomp. 186°, and with aldehydes stable, well-crystallised benzylidene derivatives, which can be prepared directly from chrysoidine and aldehyde (2 mols.). Thus benzaldehyde and chrysoidine afford the compound $C_{26}M_{20}N_4$, bright yellow plates, m. p. 242° (*nitrosoamine*, decomp. 110°), which with 10% sulphuric acid affords benzaldehyde and 1-anilino-2-phenylaminobenziminazole, white flocks, m. p. 229°. Similarly, chrysoidine and salicylaldehyde give the compound $C_{26}H_{20}O_2N_4$, bright yellow plates, m. p. 242° (*nitrosoamine*, decomp. 125°), from which dilute sulphuric acid splits off 1 mol. of salicylaldehyde. By diazotisation in alcoholic solution and treatment with 95% alcohol, the base $C_{19}H_{16}N_4$ was converted into 1-*anilino*-2-*phenylbenziminazole*, snow-white prisms, m. p. 211° (*picrate*, decomp. 199°; *picronolate*, decomp. 220°; *nitrosoamine*, decomp. 137°), and this on reduction with hydriodic acid gives the known 2-phenylbenziminazole.

[With F. ELFLEIN and K. MÜLLER.]—The action of benzyl chloride on benzeneazo-β-naphthylamine, either alone or in acetic acid solution, gives aniline and 2-phenylnaphthiminazole. Similar results were obtained with *p*-tolueneazo-β-naphthylamine, *o*- and *m*-nitrobenzeneazo-β-naphthylamine, and *p*-anisoleazo-β-naphthylamine. Similarly, benzeneazo-β-benzylnaphthylamine (shining, light red needles, m. p. 136—138°), obtained by coupling benzyl-β-naphthylamine with benzene diazonium chloride in alcoholic solution, on boiling with alcoholic hydrochloric acid decomposes into aniline and 2-phenylnaphthiminazole. Similar results were obtained with *p*-tolueneazo-benzyl-β-naphthylamine and nitrobenzeneazobenzyl-β-naphthylamine. R. B.

Harmine and Harmaline. VII. Synthesis of *apo*Harmine and of certain Carboline and Copyrine Derivatives. W. Lawson, W. H. Perkin, jun., and R. Robinson (*J. Chem. Soc.*, 1924, **125**, 626—657).—2-Chloropyridine and *o*-phenylenediamine condense to give *o*-aminophenyl-2-pyridylamine hydrochloride,



(I.) (II.)

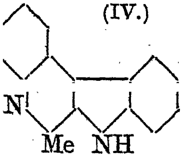


(III.)

which, when treated with nitrous acid, yields 1-α-*pyridylbenzotriazole* (I), colourless needles, m. p. 110—111°. The latter, when heated in small quantities with zinc chloride, gives 3-*carboline* (II), colourless needles, m. p. 210°; *hydrochloride*, needles from dilute hydrochloric acid; *mercurichloride*, needles; *hydrogen oxalate*, needles from dilute oxalic acid solution; *picrate*, canary-yellow needles, m. p. 260—264°. 2-Chloroquinoline and *o*-phenylenediamine similarly give 1-α-*quinolylbenzotriazole*, colourless prisms or needles, m. p. 145°, which, when heated, gives quinindoline, identical with that of Gabriél and Eschenbach (A., 1898, i, 199). The triazole (III) cannot be prepared by this method owing to the inactivity of β-halogen substituents in the pyridine molecule, and alternatively the preparation of 3-aminoquinaldine and 3-amino-2-methylpyridine was undertaken for condensation with the requisite halogen derivatives. 2-Methylquinoline-3 : 4-dicarboxylic acid (cf. Pfitzinger, A., 1898, i, 207), when strongly heated, gives the *anhydride*, colourless prisms, m. p. 218°, and when heated with carbamide at 230° gives the *imide*, pale yellow needles from ethyl acetate, m. p. 257°. The imide, when treated with bromine and potassium hydroxide, gives 3-*amino*-2-*methylquinoline*-4-*carboxylic acid*, pale yellow needles, m. p. 221—222° (decomp.), which, when heated at 225°, is smoothly converted into 3-amino-2-methylquinoline, m. p. 160—160·5°, identical with that prepared by Stark (A., 1907, i, 973). The condensation of this aminoquinaldine with various chlorobenzene derivatives could not be carried out, and is still under investigation.

Ethyl β-aminocrotonate and ethyl cinnamoylpyruvate condense to give *ethyl styrylmethylpyridinedicarboxylate*, which is isolated as a picrate, yellow needles, m. p. 147·5—148°. These, on treatment with ammonia and subsequent hydrolysis, give *styrylmethylpyridine*-

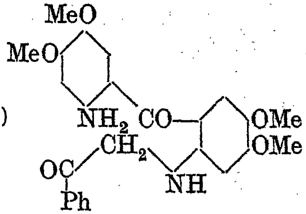
dicarboxylic acid, pale yellow prisms, m. p. 220—221°. This acid cannot be 4-styryl-2-methylpyridine-3 : 6-dicarboxylic acid, since, when boiled with aniline, it gives a *phenylimide*, which was isolated in two forms, (*a*), bright yellow needles, m. p. 228—230°, (*b*), yellow needles, m. p. 203—204°; *a* and *b* may be geometrical stereoisomerides, although *a* on recrystallisation from xylene gave *b*. The potassium salt of the dicarboxylic acid, on treatment with potassium permanganate, gives 2-*methylpyridine*-3 : 4 : 6-*tricarboxylic acid*, which was isolated as the *potassium barium* salt, colourless crystals, and also gives a *monopotassium* salt, colourless prisms, a characteristic *ferrous* salt, red or orange-brown prisms, and on treatment with an excess of aniline gives the *anilide phenylimide*, pale yellow needles, m. p. 237°, and also the *phenylimide* of 2-methylpyridine-3 : 4-dicarboxylic acid, colourless plates, m. p. 190°. The *tricarboxylic acid* itself crystallises from water in prisms $+3H_2O$, which, when anhydrous, darken at 219° and melt at 223° (decomp.), and was found not to be identical with the methylpyridinetricarboxylic acid obtained by Dobbie and Lauder (T., 1902, **81**, 154) from corydaline, the constitution of which is therefore still in doubt. The tricarboxylic acid in turn gives 2-methylpyridine-3 : 4-dicarboxylic acid, m. p. 252—256°. The synthesis of a substituted dibenzo*apo*harmine of the type (IV) was then undertaken in order that subsequent oxidation of the benzene nuclei should furnish *apo*harmine. Veratrone, the preparation of which from veratric acid has been greatly improved, was converted by nitric acid into 6 : 6′-*dinitro*-3 : 4 : 3′ : 4′-*tetramethoxybenzophenone* (dinitroveratrone), colourless needles from acetic acid, m. p. 225°, and the latter on reduction gives *diaminoveratrone*, yellow prisms, m. p. 210°. The 6 : 6′-position of the nitroxyl groups in dinitroveratrone is confirmed by converting diaminoveratrone into *diacetyldiaminoveratrone*, pale yellow needles, m. p. 203°, which, on treatment with nitric acid in acetic acid suspension, gives a theoretical yield of 6-nitroacetoveratrylamine (cf. Jones and Robinson, T., 1917, **111**, 914).

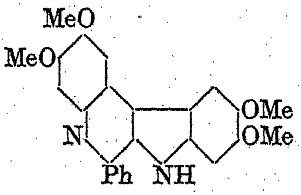


(IV.)

Diaminoveratrone, when heated with ω-bromoacetophenone in acetic acid, gives the hydrobromide of N-*phenacyldiaminoveratrone*, the *base* itself (V) forming greenish-yellow needles, m. p. 185—186° (decomp.). The base, when treated in alcoholic suspension with 30% aqueous potassium hydroxide, gives *phenyldiveratroharmyrine* (phenyldiveratro-7-pyridole) (VI), which crystallises from methyl alcohol +1 mol. of solvent, prisms, m. p. 145—148° (decomp.).

(V.)



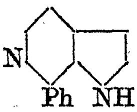


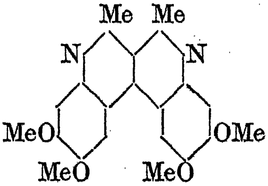
(VI.)

Replacement of the ω-bromoacetophenone by bromoacetone gave no compound analogous to *N*-phenacyldiaminoveratrone, but *methyldiveratroharmyrine* was obtained, colourless prisms, m. p. 254°, and gave a *methosulphate*, orange-yellow needles. The hydrobromide, on boiling with hydriodic acid, was completely demethylated, giving *methyltetrahydroxydibenzoharmyrine hydriodide*, yellow needles. Methyl- and phenyl-diveratroharmyrine were found on oxidation and subsequent treatment with alkali to give, however, only a minute yield of the corresponding *apo*harmine (VII), owing to almost complete destruction of the base by the oxidising agent.

2 : 7-Naphthyridine (copyrine) rings may be synthesised also from the 2 : 2-diaminobenzophenones. Thus diaminoveratrone condenses with acetylacetone to give *dimethyldiveratrocopyrine* (VIII), colourless needles from *n*-butyl alcohol, m. p. 230—231°, forming a yellow, crystalline *nitrate*, and a *picrate* of composition $3C_{22}N_{22}O_4N_2\cdot5C_6H_3O_7N_3$, yellow needles, decomp. 245°. Diaminoveratrone with benzoylacetone gives similarly *phenylmethyldiveratrocopyrine*, colourless needles, m. p. 270°; with dibenzoylmethane gives *diphenyldiveratrocopyrine*, yellow needles, m. p. 362°, and with 1 : 3-diketohydrindene gives o-*phenylenediveratrocopyrine*, isolated as the *acetate*, yellow needles, the latter being converted by ammonia into the *base*, yellow needles, from nitrobenzene–*n*-butyl alcohol, m. p. 304°. Diaminoveratrone condenses also with ethyl acetoacetate to give *hydroxymethyldiveratrocopyrine*, pale yellow needles from quinoline, m. p. 320—330°; with ethyl malonate to give *dihydroxydiveratrocopyrine*, yellow needles from nitrobenzene, m. p. 300° (decomp.); with ethyl cyanoacetate to give *aminohydroxydiveratrocopyrine*, salmon-coloured needles from alcohol–nitrobenzene, decomp. 280°, chars 280—290°.

(VII.)





(VIII.)

Xanthone (*oo*′-dichlorobenzophenone) can be prepared by the dry distillation of calcium *o*-chlorobenzoate. A mixture of ethyl benzoylacetate and ethyl β-aminocrotonate, when boiled in methyl-alcoholic potassium hydroxide, yields 6-hydroxy-4-phenyl-2-methylpyridine-3-carboxylic acid (cf. Ruhemann, T., 1899, **75**, 412).

The following synthesis of a dimethoxykynurenic acid has been accomplished. Acetoveratrone on nitration does not yield 4 : 5-dinitroveratrole (Harding, T., 1914, **105**, 2795), but 6-*nitroacetoveratrone*, pale yellow needles, m. p. 133—133·5°, in which the 6-position of the nitro group is shown by further nitration, giving 4 : 5-dinitroveratrole. 6-*Nitroacetoveratrone* condenses with anisaldehyde to give 6-*nitro*-3 : 4-*dimethoxyphenyl* 4-*methoxystyryl ketone*, pale-yellow prisms from ethyl acetate, m. p. 170°, and also gives a *piperonylidene* derivative, plates and needles, m. p. 176—177°, re-solidify and then re-melt above 200° (indef.). The 6-nitro compound on reduction gives 6-*aminoacetoveratrone*, colourless prisms, m. p. 133°, and when treated with sodium ethoxide and ethyl oxalate in alcohol yields 6-*nitroveratroylpyruvic acid* (IX), needles, m. p. 163°. The latter, when reduced with ferrous hydroxide,

(IX.)  (X.)

gives 4-*hydroxy*-6 : 7-*dimethoxyquinoline*-2-*carboxylic acid* (dimethoxykynurenic acid) (X), needles, sintering at 260°, m. p. 270° (decomp.). This acid when heated in glycerol solution loses carbon dioxide, giving 4-*hydroxy*-6 : 7-*dimethoxyquinoline*, colourless prisms, softening at 165—170°, re-solidifying and melting at 226°.

5 : 7-Dibromoisatin was converted into 5 : 7-dibromoisatinic acid, and the latter into 6 : 8-*dibromo*-2-*methylquinoline*-4-*carboxylic acid*, colourless needles, m. p. 267° (decomp.). The latter on heating gives 6 : 8-*dibromo*-2-*methylquinoline*, needles, m. p. 100°, *picrate*, orange-yellow needles, m. p. 155°. Attempts made to replace the bromine in the carboxylic acid by hydroxy groups and then by oxidation of the benzene nucleus to obtain 2-methylpyridine-4 : 5 : 6-tricarboxylic acid failed. F. G. M.

Harmine and Harmaline. VIII. Constitution of certain Harmaline Derivatives. H. Nishikawa, W. H. Perkin, jun., and R. Robinson (*J. Chem. Soc.*, 1924, **125**, 657—663).—Methylharmaline on oxidation with potassium permanganate in acetone solution yields keto*iso*normethyltetrahydroharmine; acetylharmaline when thus oxidised yields *acetylketotetrahydronorharmine* (III), colourless prisms, m. p. 207—208°, and when reduced with hydrogen in the presence of palladium gives acetyltetrahydroharmaline.

(I.) 
 (II.)

(III.) 
 (IV.)

It follows that methyl- and acetyl-harmaline have the constitution (I) and (II). Harmaline methosulphate on treatment with potassium cyanide gives *cyanomethyltetrahydroharmine*, colourless leaflets, m. p. 155—156°, whilst harmine methosulphate gives a similar but unstable product, m. p. 141°. Acetylketotetrahydronorharmine on hydrolysis with alcoholic potassium hydroxide yields *6-methoxy-3-β-aminoethylindole-2-carboxylic acid* (IV), leaflets, decomp. 220—250°, and the corresponding *lactam, ketotetrahydronorharmine*, prisms, m. p. 198°. The lactam could not be hydrolysed to the amino-acid, or the latter dehydrated to the lactam. Hydratoacetylharmaline, which forms a *hydrochloride* (+0·5 aq.), colourless needles, on acetylation gives two isomeric *diacetylhydratoacetylharmalines*, (*a*) needles, m. p. 134—135°, (*b*) pale-yellow plates, m. p. 159—160°. The work of O. Fischer (A., 1898, i, 164; 1914, i, 316) is thus confirmed. F. G. M.

Dyes Derived from Phenanthraquinone. IV. Anilinoflavindulines and Phenanthraquinoneazo-dyes. A. C. Sircar and D. C. Roy (*J. Chem. Soc.*, 1924, **125**, 543—547; cf. T., 1913, **103**, 295; 1921, **119**, 1211; 1922, **121**, 1944).—The following phenanthraphenazonium compounds containing an anilino group attached to the benzenoid nucleus did not exhibit the expected property of dyeing in blue shades.

4 : 5-*Dibromo*-11-*anilinoflavinduline chloride*, prepared by reducing nitrosodiphenyl-*m*-phenylenediamine and condensing the product with 4 : 5-dibromophenanthraquinone, green crystals, decomp. 199°, m. p. 245—252°. 2 : 7-*Dinitro*-11-*anilinoflavinduline chloride*, similarly prepared (not crystalline), blackens at 250°, m. p. above 270°. 2-*Nitro*-11-*anilinoflavinduline chloride*, prisms, m. p. above 270°. 2 : 7-*Diamino*-11-*anilinoflavinduline chloride*, bluish-black flocculent precipitate, m. p. above 275°. 4 : 5 : 11-*Trianilinoflavinduline chloride*, prepared from the above 4 : 5-dibromo compound by the action of aniline in the presence of copper powder, is a flocculent precipitate, decomp. 165°, m. p. 205—210°.

The following azo compounds were prepared by coupling the diazotised aminophenanthraquinone with the hydroxy acid in alkaline solution. 1-Hydroxy-2-naphthoic acid with 2-aminophenanthraquinone gives 4-*hydroxy*-1(2′)-*phenanthraquinoneazo*-3-*naphthoic acid*, m. p. not below 275°; with 4-aminophenanthraquinone gives 4-*hydroxy*-1(4′)-*phenanthraquinoneazo*-3-*naphthoic acid*; with 2 : 7-diaminophenanthraquinone gives *phenanthraquinone*-2 : 7-*bis*(1-*azo*-4-*hydroxy*-3-*naphthoic acid*), m. p. not below 283°; with 4 : 5-diaminophenanthraquinone gives *phenanthraquinone*-4 : 5-*bis*(1-*azo*-4-*hydroxy*-3-*naphthoic acid*), amorphous, m. p. above 275°.

2-Hydroxy-3-naphthoic acid with 2-aminophenanthraquinone gives 2-*hydroxy*-1(2′)-*phenanthraquinoneazo*-3-*naphthoic acid*, blue crystals, decomp. 225°; with 4-aminophenanthraquinone gives 2-*hydroxy*-1(4′)-*phenanthraquinoneazo*-3-*naphthoic acid*, decomp. 250—255°; with 2 : 7-diaminophenanthraquinone gives *phenanthraquinone*-2 : 7-*bis*(1-*azo*-2-*hydroxy*-3-*naphthoic acid*), crystals, m. p. not below 283°; with 4 : 5-diaminophenanthraquinone gives *phenanthraquinone*-4 : 5-*bis*(1-*azo*-2-*hydroxy*-3-*naphthoic acid*), m. p. not below 274°. Salicylic acid gives with 4-aminophenanthraquinone *phenanthraquinone-4-azosalicylic acid*, m. p. not below 275°; with 2 : 7-diaminophenanthraquinone gives *phenanthraquinone-2 : 7-bis-azosalicylic acid*, m. p. not below 270°; with 4 : 5-diaminophenanthraquinone gives *phenanthraquinone-4 : 5-bisazosalicylic acid*, m. p. not below 274°. The dyeing properties on wool of the above compounds and the colours developed in sulphuric acid solution are described. F. G. M.

Reaction of Azine and Thiazine Dyes with the Gel of *Chondrus crispus*. E. JUSTIN-MUELLER (*Bull. Soc. chim.*, 1924, **35**, 390—394).—Azine and thiazine dyes coagulate solutions of the gel obtained from lichen carragheen, *Chondrus crispus*. This property is not possessed by the oxazines, and appears to be characteristic of the "az-azonium" and "az-thionium" groupings. R. B.

Catalysis. IV. Behaviour of the Amino Group when Cytosine and Nitrouracil are reduced in the Presence of Colloidal Platinum. E. B. BROWN and T. B. JOHNSON (*J. Amer. Chem. Soc.*, 1924, **46**, 702—708).—Cytosine is reduced by hydrogen in the presence of colloidal platinum with formation of hydrouracil and ammonia. Partial reduction of 5-nitrouracil with three molecular equivalents of hydrogen forms 5-aminouracil, which compound undergoes partial hydrolysis with the production of 5-hydroxyuracil (*iso*barbituric acid); with four molecular equivalents of hydrogen the hydrolysis proceeds further and a new *compound* (I) or (II) (?) is obtained. It forms diamond-shaped crystals not melting at 285°. Yeast-nucleic acid was also submitted to the action of hydrogen in presence of colloidal platinum, and evidence of the formation of ammonia obtained. C. J. S.

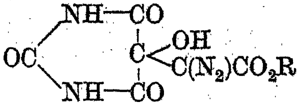
(I.)

$CO<\begin{matrix}NH-CO\\NH\cdot CH_2\end{matrix}>CH\cdot OH$

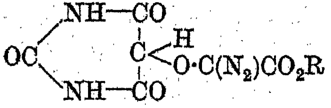
$CO<\begin{matrix}NH-CO\\NH\cdot CH_2\end{matrix}>CO$

(II.)

Interaction of Ethyl Diazoacetate and Alloxan. H. BILTZ and E. KREMER (*Annalen*, 1924, **436**, 154—173).—Ethyl diazoacetate combines with alloxan to give ethyl dialuryldiazoacetate (I) or (II).



(I.)



(II.)

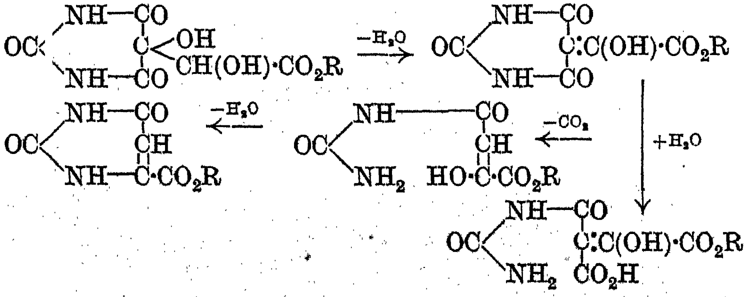
Formula I best explains the results of methylation (to give trimethyl derivative) and the decomposition effected by alkalis, acids, and oxidising agents. Formula II is also possible, since the ester cannot be acetylated, and since among its reduction products are formed dialuric acid and alloxantin.

Ethyl dialuryldiazoacetate is produced by the interaction of alloxan hydrate (1 mol.) and ethyl diazoacetate (2·5 mols.), when yellow, six-sided plates, decomp. 163—164°, are obtained. The *disodium* salt, $C_8H_6O_6N_4Na_2$, is described. Nitrogen is evolved when the ester is treated with dilute mineral acids or Fehling's solution. *Methyl dialuryldiazoacetate* (from alloxan hydrate and methyl diazoacetate), forms six-sided, yellow needles, decomp. 153—154°.

Ethyl methyl dialuryldiazoacetate (from methylalloxan hydrate) forms prisms, decomp. 136°. Methylalloxan will not give a solid derivative with methyl diazoacetate, whilst dimethylalloxan will not react with either ester.

Methyl 1 : 3 : 5-*trimethyldialuryldiazoacetate* is produced when ethyl dialuryldiazoacetate and diazomethane react in ethereal solution. It forms clusters of prisms, m. p. 99—100°, and when warmed with dilute sulphuric acid affords two atoms of nitrogen. When oxidised with concentrated nitric acid, dimethylalloxan anhydride and oxalic acid are produced; with hydroxylamine, it gives dimethylvioluric acid.

Ethyl dialuryldiazoacetate, on warming with *N*/2-sodium hydroxide, evolves nitrogen, and on acidification, ethyl uracilcarboxylate and carbon dioxide are produced. Uracilcarboxylic acid is also formed in the above reactions, as microscopic needles, m. p. not below 330°, and was characterised as the 5-nitro derivative. The formation of these compounds must take place according to the scheme :



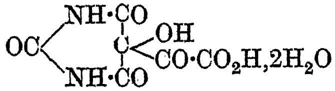
Ethyl dialuryldiazoacetate on hydrolysis with dilute hydrochloric acid yields ethyl glycollate and alloxantin; with concentrated hydrochloric acid, it yields dialuric acid and ethyl glyoxylate.

Another product with either dilute or concentrated hydrochloric acid is ethyl uracilcarboxylate. The methyl ester yields *methyl uracilcarboxylate* (fine needles, m. p. 230°) on hydrolysis with the concentrated acid.

Ethyl 5-ethoxyuracil-6-carboxylate results from the interaction of dialuryldiazoacetate and alcoholic hydrogen chloride, when nitrogen is evolved, and the ester may be obtained as long, colourless needles, m. p. 203—212°. The *ammonium* salt (pale, rose-coloured plates, m. p. 202—203°) and the *potassium* salt (colourless) are described, and from the latter the free *acid* may be obtained by the action of concentrated hydrochloric acid. It forms colourless prisms, decomposing at 216—217° or on heating at 190°, to give ethyl *iso*barbiturate.

Oxidation of ethyl 5-ethoxyuracil-6-carboxylate with permanganate yields oxaluric and oxalic acids.

Oxidation of ethyl dialuryldiazoacetate with concentrated nitric acid gives alloxan and oxalic acid, and with milder conditions *dialurylglyoxylic acid* dihydrate [microscopic needles, m. p. 152° (decomp.)] may be isolated (annexed formula). With hydrogen peroxide, oxaluric acid is formed.



$$OC<\begin{matrix}NH\cdot CO\\ NH\cdot CO\end{matrix}>C<\begin{matrix}OH\\ CO\cdot CO_2H,2H_2O\end{matrix}$$

Reduction of ethyl dialuryldiazoacetate with hydriodic acid gives alloxantin and ethyl iodoacetate, whereas with stannous chloride, the products are dialuric and glycollic acids. A. E. C.

Oxidation of Uric Acid. H. Biltz and H. Schauder (*J. pr. Chem.*, 1923, [ii], **106**, 108—172).—The oxidation of uric acid in dilute acetic acid suspension at 0°, using potassium permanganate (2·6 atoms of oxygen), affords potassium oxalurate and oxalate, carbamide, and oxalyldiureide; when the permanganate used affords 1 atom of oxygen, the same products except the oxalurate are obtained. Oxidation of uric acid with potassium persulphate in presence of potassium acetate is less vigorous than the above and requires water-bath temperatures; when persulphate equivalent to 1 atom of oxygen is used, allantoin results, 2 atoms of oxygen affording potassium oxalurate and oxalyldiureide. Oxidation of uric acid at 0° in aqueous suspension using permanganate (=2 atoms O) in presence of a rapid current of carbon dioxide gives the products obtained by using acetic acid, whilst with permanganate equivalent to 1 atom of oxygen, potassium oxalurate and oxalate and carbamide result. No uroxanic acid is isolated, probably because its precursor, the hypothetical hydroxyacetylenediureinecarboxylic acid, loses carbon dioxide before passing into uroxanic acid.

When uric acid is boiled with aqueous hydrogen peroxide until it is all dissolved, carbonyl dicarbamide is the main product, and is accompanied by a trace of cyanuric acid and a *substance* forming white, hemispherical masses, decomp. 220°. The results are unaffected by adding small quantities of acetic acid or of potassium acetate.

Oxidation of uric acid by permanganate (=1 atom O) at the ordinary temperature in presence of sulphuric acid gives alloxan and alloxantin, whilst if the acid is boiled with aqueous potassium persulphate solution (=1 atom O) alloxan is formed in small quantities, the majority of the acid probably passing into alloxanic acid and the latter into 5-hydroxyhydantoin (A., 1921, i, 815). When twice the above proportion of persulphate is used, a little parabanic acid is formed, presumably from alloxan.

Hydrogen peroxide converts uric acid in presence of boiling dilute sulphuric acid into parabanic acid (formed from alloxan). In presence of boiling dilute hydrochloric acid, the oxidation is so satisfactory that the author recommends this as a method of preparing parabanic acid.

Possible intermediate compounds in the oxidation of uric to oxaluric acid are uric acid glycol, alloxan, allantoin, or the hypothetical hydroxyacetylenediureinecarboxylic acid. These compounds require for their formation (from uric acid) 1 atom of oxygen, this amount of oxygen being required to convert them into oxaluric acid. The compounds have therefore been oxidised under different conditions. Uric acid 4 : 5-glycol, when treated with permanganate (=1 atom O) in dilute acetic acid at 0°, is very slowly oxidised and affords impure potassium oxalurate and oxalate. In boiling solution, oxidation is rapid, but the yield of oxalurate is small. The glycol is therefore not the intermediate between uric and oxaluric acids.

9-Methyluric acid 4 : 5-glycol, oxidised with permanganate and acetic acid in the warm, gives methyloxaluric acid (?), m. p. 180—190° (with frothing). 7 : 9-Dimethyluric acid 4 : 5-glycol similarly affords small quantities of dimethylparabanic acid.

Alloxan is very slowly oxidised by cold permanganate and dilute acetic acid to give potassium oxalurate. Oxidation is more rapid in the warm, but alloxan is clearly not the intermediate sought for. Hydrogen peroxide oxidises alloxan at water-bath temperatures to give oxaluric acid.

Allantoin is slowly oxidised by cold and rapidly by warm permanganate, potassium oxalurate and carbamide resulting. Allantoin is ruled out as the intermediate oxidation product, which is evidently the hypothetical hydroxyacetylenediureinecarboxylic acid.

A method is given for the preparation of potassium oxalurate from uric acid and consists in the oxidation of the latter in alkaline solution, and then in acetic acid solution, using permanganate equivalent to one atom of oxygen for each stage. Potassium oxalurate ($C_3H_3O_4N_2K,H_2O$), when treated with hydrochloric acid, affords *oxaluric acid*, decomp. 208—210°. The *ammonium* salt is described. *Methyl oxalurate*, from the acid and diazomethane, forms crystals, m. p. 192° (indef. with frothing). *Oxaluric methylamide*, from the ester and aqueous methylamine, forms needles, decomp. 251—253°. When oxaluric acid is boiled for a short time with water, carbamide oxalate and ammonium tetraoxalate result. The monocarbamide oxalate described by Lubavin (1872) does not exist. If equimolecular quantities of carbamide and oxalic acid are mixed in aqueous solution, carbamide oxalate, $H_2C_2O_4,2CO(NH_2)_2$, separates, whilst if the solution is boiled for some time, ammonium oxalate is formed.

When 1 : 3-dimethyluric acid is oxidised with alkaline permanganate (=1 atom O), potassium oxalurate and *s*-dimethyloxamide result. Alkaline oxidation (1 atom O) followed by acid oxidation (acetic; 1 atom O) affords potassium oxalurate and dimethylparabanate, together with *s*-dimethyloxamide and oxaluric methylamide. Oxidation (1 atom O) in acetic acid solution gives dimethylparabanic acid and a crystalline *substance* (not examined), oxidation with 2 atoms of oxygen (as permanganate) affording potassium oxalurate and dimethylparabanic acid. Oxidation of 1 : 3-dimethyluric acid with alkaline hydrogen peroxide affords a *substance* forming needles, m. p. 215° (decomp.).

3 : 7-Dimethyluric acid when oxidised by alkaline permanganate (1 atom O) gives 1 : 8-dimethylallantoin together with a *potassium* salt, $C_6H_4O_5N_3K$, plates, m. p. 275° (indef. and decomp.) (corresponding with an *acid*, $C_6H_5O_5N_3$, prisms, decomp. 212°). 3 : 7-Dimethyluric acid is converted by alkaline hydrogen peroxide into carbonyl dicarbamide (?), decomp. 210°.

No alloxan is formed when chlorine is passed into a suspension of uric acid in aqueous sodium acetate–acetic acid. No alloxans are formed when 9-methyluric acid glycol is heated with hydrochloric acid, the products being carbamide and methylparabanic acid. Similarly treated, 7 : 9-dimethyluric acid glycol affords carbamide and dimethylparabanic acid. The glycol type is therefore not intermediately formed when uric acids are oxidised to alloxans.

5-Chloro- and 5-hydroxy-ψ-uric acids are readily converted by hydrochloric acid into alloxan, which is conveniently identified by adding stannous chloride and isolating alloxantin.

The chloraluric acid described by Schiel (1859) is, as stated by Lubavin (*loc. cit.*), a mixture of ammonium chloride and parabanic acid. The stryphnic acid obtained by Gibbs (1869) on treating uric acid with potassium nitrite and mineral acid, is now shown to be a mixture of allantoin with oxaluric and oxalic acids. Similarly, the urinilic acid described by Sokolov (1869) does not exist; nitric oxide has no action on an aqueous suspension of uric acid, whilst nitrogen peroxide has no action on uric acid in absence of water; nitric oxide containing a little nitrogen peroxide converts uric acid, in aqueous suspension, into uric acid glycol, parabanic acid, and alloxan, whilst nitric oxide containing much nitrogen peroxide affords xanthine, parabanic acid, alloxan, and oxalic acid.

The paper contains a useful discussion of the results obtained.

E. E. T.

Potassium Hydroxyhæmin. A. Hamsik (*Z. physiol. Chem.*, 1924, **133**, 173—179).—The author has previously (*Spisy lékařské fakulty v Brně*, 1922, **1**, 1A, 5), by extracting the coagulum of blood with alcohol acidified with oxalic acid, obtained a compound $C_{34}H_{31}O_4N_4Fe$, small star-like aggregates of crystals, which he named hydroxyhæmin anhydride. By boiling the anhydride with glacial acetic acid and sodium chloride or with alcohol, oxalic acid, and sodium chloride, α-chlorohæmin was obtained. Potassium hydroxyhæmin, $C_{34}H_{30}O_4N_4K_2Fe\cdot OH$, very small spherical, crystalline aggregates, was obtained by treating hydroxyhæmin anhydride or α-chlorohæmin with alcoholic potassium hydroxide.

S. S. Z.

A New Type of Cyclic Compound. E. P. Kohler (*J. Amer. Chem. Soc.*, 1924, **46**, 503—517; cf. A., 1916, i, 404; 1919, i, 582).—Improved methods are described for the preparation of phenyl γ-nitro-β-phenylpropyl ketone and of its α-bromo derivative, which occurs in two stereoisomeric forms, needles, m. p. 108°, and plates or prisms, m. p. 129°, and is accompanied, in its formation, by the *αα-dibromo* derivative, tablets, m. p. 106°. The α-bromo derivative, when treated with potassium acetate in methyl-alcoholic solution, affords a mixture of the *cyclo*propane derivative previously described with *2-hydroxy-3-methoxy-5-benzoyl-4-phenylisoxazolidine* and an unidentified oxazole (?) derivative. If the isoxazolidine (prisms, m. p. 162°) is dissolved in glacial acetic acid and the solution poured into water, *2 : 3-dihydroxy-5-benzoyl-4-phenylisoxazolidine*, prisms, m. p. 153°, results (*dibenzoyl* derivative, tablets, m. p. 158—160°). The isoxazolidine (m. p. 162°), when treated with ammonia, affords *3-amino-2-hydroxy-5-benzoyl-4-phenylisoxazolidine*, needles, m. p. about 162° (decomp.); this substance, when boiled with ethyl alcohol in presence of acetic acid, being converted into *2-hydroxy-3-ethoxy-5-benzoyl-4-phenylisoxazolidine*, m. p. 168° (decomp.), boiling with methyl alcohol etc. affording the above methoxy compound. The latter, when treated with acetic anhydride, is slowly converted into *phenyl γ-nitro-α-acetoxy-β-phenylpropyl ketone* (tablets, m. p. 98°), which with ammonia affords the corresponding *α-hydroxy* compound (m. p. 142°; *benzoyl* derivative, needles, m. p. 106—107°). The last-named hydroxy compound, when treated with hydrogen chloride in methyl-alcoholic solution, is converted into the methoxyisoxazolidine of m. p. 162°. The formation from the latter of the above ketone (m. p. 98°) takes place through the intermediate production of *5-benzoyl-4-phenylisoxazoline oxide*, colourless tablets, m. p. 126° (annexed formula). This compound, which results when the above α-bromoketone is treated with potassium acetate in *iso*propyl-alcoholic solution, combines with water, and with primary (but not with secondary) alcohols, in presence of acid, to give isoxazolidines, water, *e.g.*, affording the dihydroxyisoxazolidine mentioned above, whilst ammonia affords the above aminohydroxyisoxazolidine. The isoxazolidines described form sparingly soluble copper salts. The methoxyisoxazolidine, which is converted at its m. p. into methyl alcohol, water, benzonitrile, and a nitrogenous substance, affords a *benzoyl* derivative (colourless plates, m. p. 114°) and a *copper* derivative, $C_{17}H_{17}O_5NCu$, and (like the isoxazoline oxide) is converted by alkali into benzonitrile, and formic and phenylacetic acids.

Indoxazens and *iso*Oxazoles. K. VON AUWERS (*Ber.*, 1924, 57, [*B*], 461—467).—A comparison of the optical properties of indoxazen with those of *iso*oxazole and its derivatives confirms the structure,  $C_6H_4<\overset{CH}{\underset{O}{>}}N$, ascribed to the former compound by Conduché (A., 1908, i, 154). The following data, amongst others, are recorded. *iso*Oxazole, b. p. 95°, d_4^{20} 1·078, n_{He}^{20} 1·428. 5-Methyl-*iso*oxazole, b. p. 122°, d_4^{20} 1·023, n_{He}^{20} 1·439. 3-Methyl*iso*oxazole, b. p. 118°, d_4^{20} 1·022, n_{He}^{20} 1·435. 3 : 5-Dimethyl*iso*oxazole, b. p. 143°, d_4^{20} 0·983, n_{He}^{20} 1·442. 3 : 4 : 5-Trimethyl*iso*oxazole, b. p. 111°/75 mm., d_4^{20} 0·981, n_{He}^{20} 1·452. 3 : 4-Tetramethylene*iso*oxazole,

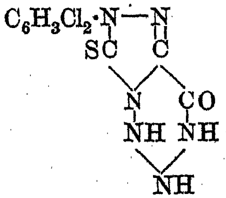
$C_6H_8\lessdot\begin{matrix}CH\\N\!-\!-\end{matrix}\!>\!O$, b. p. 93°/15 mm., d_4^{20} 1·095, n_{He}^{20} 1·498. Methyltetrahydrobenzo-3 : 4-*iso*oxazole, b. p. 97°/16 mm., d_4^{20} 1·059, n_{He}^{20} 1·491. Methyltetrahydrobenzo-4 : 5-*iso*oxazole, b. p. 101°/18 mm., d_4^{20} 1·062, n_{He}^{20} 1·492.

Indoxazen, b. p. 84°/11 mm., d_4^{20} 1·170, n_{He}^{20} 1·563. 3-Phenylindoxazen, $C_6H_4<\begin{matrix}CPh\\-O-\end{matrix}\!\gtrdot N$, m. p. 83—84°, b. p. 181°/13 mm., $d_4^{39\cdot9}$ 1·1241, $n_{He}^{39\cdot9}$ 1·59279. Salicylonitrile, $d_4^{99\cdot6}$ 1·1052, $n_{He}^{99\cdot6}$ 1·54359. *o*-Methoxybenzonitrile, b. p. 146°/20 mm., d_4^{20} 1·107, n_{He}^{20} 1·548. *o*-Anisaldoxime methyl ether, b. p. 235°, d_4^{20} 1·092, n_{He}^{20} 1·554.

Attempts to convert *o*-aminoacetophenone into 3-methylindoxazen gave unexpectedly methylanthranil, $C_6H_4\lessdot\begin{matrix}CMe\\N\!-\!-\end{matrix}\!>\!O$, b. p. 121°/17 mm., $d_4^{23\cdot2}$ 1·1304, $n_{He}^{23\cdot2}$ 1·57457. H. W.

Synthesis of Thiobiazolone Derivatives. C. Bülow and F. Seidel (*Ber.*, 1924, **57**, [*B*], 357—362).—Thiobiazolone sulphides may be obtained simply by the action of potassium xanthate on the 2 : 4-dichlorophenylhydrazone of ethyl α-chloroglyoxylate and analogous substances (cf. Bülow and Neber, A., 1913, i, 207, 999; 1916, i, 845).

The 2 : 4-dichlorophenylhydrazone of ethyl α-chloroglyoxylate, $C_6H_3Cl_2\cdot NH\cdot N{:}CCl\cdot CO_2Et$, is converted by potassium xanthate in warm alcoholic solution into *ethyl* 5-*thio*-4-op-*dichlorophenylthiobiazolone-2-carboxylate*,  $\left.\begin{matrix}N(C_6H_3Cl_2)\cdot CS\\ N{=}C(CO_2Et)\end{matrix}\right>S$, small, colourless needles, m. p. 122°, which is transformed by an alcoholic solution of ammonia into the corresponding *amide*, $C_9H_5ON_3S_2Cl_2$, colourless needles, m. p. 235°; the hydrolysis of the ester or amide to the acid could not be effected. A *substance*, $C_{21}H_{16}O_4N_4Cl_4S_2$, m. p. 158—160° or 173° (when crystallised from alcohol or acetic acid, respectively) is obtained as by-product of the preparation of the ester. The latter compound is converted by prolonged treatment with an excess of hydrazine hydrate in boiling alcoholic solution into the *triazole* derivative,  $\left.\begin{matrix}N{=}CH\\ N(C_6H_3Cl_2)\cdot CS\end{matrix}\right>N\cdot NH_2$, colourless needles, m. p. 153°; under somewhat different conditions, a *product*, $C_9H_6ON_6Cl_2S$, colourless needles, m. p. 196—197° (decomp.) after softening at 191—192°, is obtained, to which the annexed constitution is ascribed.



When acetone is used as solvent in place of alcohol, the action between potassium xanthate and the 2 : 4-dichlorophenylhydrazone of ethyl α-chloroglyoxylate follows a different course and leads to the production of the *sulphide*, $S[C(CO_2Et){:}N\cdot NH\cdot C_6H_3Cl_2]_2$, hygroscopic crystals, m. p. 175—176°, which can also be obtained by the action of ammonium sulphide on the chloro ester.

2 : 4-Dichlorophenylhydrazonopyruvyl chloride does not appear

to be convertible by potassium xanthate into a thiobiazolone; it is transformed by potassium xanthate or colourless ammonium sulphide in the presence of acetone into the *sulphide*,

$S(CAc{:}N{\cdot}NH{\cdot}C_6H_3Cl_2)_2$,

a yellow substance, m. p. 220—222° (decomp.) after becoming black at about 180°. H. W.

o-Hydroxyazoxy Compounds. D. Bigiavi and R. Poggi (*Gazzetta*, 1924, **54**, 114—131).—The authors have investigated the pairs of isomeric azoxy compounds obtained from benzeneazo-*p*-cresol and its derivatives when these are oxidised by means of peracetic acid. That *p*-hydroxyazo compounds exhibit the hydroxylic and not the quinonephenylhydrazonic structure was shown by McPherson (A., 1896, i, 27; 1900, i, 123) and by Willstätter and Veraguth (A., 1907, i, 453), who found that the acyl derivatives of benzeneazophenol are different from the compounds resulting from benzoquinone and the *as*-acylphenylhydrazines. For the corresponding ortho compounds no such difference has been encountered, and their tardy solubility in alkali, their failure to react with ammonia in an anhydrous solvent, and various other physico-chemical considerations incline certain authors (cf. Farmer and Hantzsch, A., 1900, i, 122; Puxeddu and Gennari, A., 1922, i, 587) to prefer the quinonoid to the hydroxyazoic structure for *o*-hydroxyazo derivatives.

The assumption of different constitutions for *o*- and *p*-hydroxyazo compounds seems, however, unwarranted, and, indeed, in many reactions benzeneazo-*p*-cresol behaves similarly to *p*-hydroxyazobenzene. Thus, its ready formation of two isomeric azoxy compounds is not easy to explain on the basis of the quinonoid structure. Moreover, the similarity is borne out by (1) the formation of unstable hydrazophenols when the *o*-hydroxyazo compounds are reduced by either aluminium amalgam in ethereal solution or zinc and ammonium chloride, (2) the formation, by the action of nitrous acid, of a nitro derivative containing the nitro group in the cresol nucleus, and the formation of bisbenzeneazo-*p*-cresol (cf. Puxeddu and Maccioni, A., 1907, i, 798) by the action of a normal diazotate.

The structures of the two benzeneazoxycresols are determined as follows. When treated with bromine, the one, m. p. 125°, yields a dibromo derivative with a bromine atom in each nucleus, since it gives *p*-bromoaniline and 3-bromo-6-amino-*p*-cresol on reduction; the other, m. p. 74°, gives a monobromo derivative and then a polybromo derivative which has bromine in only the cresol nucleus, as the only base volatile in a current of steam formed on reduction is aniline. It may be assumed, therefore, that the former isomeride contains the residue NPh⁚ and is the β-compound, and the latter, O⁚NPh⁚, and is the α-compound. The following observations, confirmatory of these conclusions, have been made.

Nitrous acid does not react with β-benzeneazoxycresol, but with the α-isomeride readily forms a nitro derivative which has the nitro group in the cresol nucleus and in the ortho-position towards the hydroxyl group, as it reacts with diazonium salts to form an azoazoxy derivative. Benzene-α-azoxycresol is readily oxidised by permanganate to *iso*diazobenzene and, probably, to *o*-nitrocresol; with the β-isomeride, the oxidation is extremely slow, although Bamberger gave this reaction as a means of recognising azoxyphenols. The pale yellow α-compound changes moderately rapidly to chestnut-yellow under the influence of light, but the β-isomeride retains its colour almost unaltered. Etherification of the hydroxyl proceeds normally with the α-, but with great difficulty with the β-form. The structure attributed by Baudisch (A., 1917, i, 356) to the β-*o*-hydroxyazoxybenzenes is regarded as unauthorised.

The *nitro* derivative of benzeneazocresol ($N_2 : OH : NO_2 : Me = 1 : 2 : 3 : 5$) crystallises in dark red, lustrous, plush-like needles, m. p. 130°, and is oxidised with difficulty by peracetic acid, yielding a mixture, m. p. 110°, of the two nitroazoxy compounds.

Benzene-α-azoxycresol, $O\!:\!NPh\!:\!N\cdot C_6H_3Me\cdot OH$, forms transparent, orange prisms, m. p. 73—74°, and gives a deep, blood-red coloration with concentrated sulphuric acid. Its *acetyl* derivative separates in yellow needles or transparent, prismatic crystals, m. p. 78—79°, and yields acetylhydrazocresol when reduced by means of aluminium amalgam in ethereal solution. Its *benzoyl* derivative forms pale yellow prisms, m. p. 97—101°.

*Benzene-α-azoxy-*m*-nitro-*p*-cresol*, $O\!:\!NPh\!:\!N\cdot C_6H_2(Me)(OH)NO_2$, crystallises in yellow, silky needles, m. p. 121—122°, and dissolves in alkali hydroxide or carbonate solution to a blood-red solution.

*Benzeneazobenzene-α-azoxy-*p*-cresol*,

$$O\!:\!NPh\!:\!N\cdot C_6H_2(Me)(OH)\cdot N_2Ph,$$

forms long, silky needles, m. p. 148—149°, which are almost black when moistened with benzene, but brilliant chestnut-yellow when dry. With concentrated sulphuric acid, it gives a reddish-brown coloration, and with sodium hydroxide solution containing a few drops of alcohol an intense violet coloration turning to reddish-violet when the liquid is diluted.

*Benzene-α-azoxy-*m*-bromo-*p*-cresol* crystallises in lustrous, sulphur-yellow needles, m. p. 143—144°, and dissolves in sodium hydroxide solution to a bright red solution. When brominated further, it yields the *polybromo* derivative, $C_{13}H_7O_2N_2Br_5$, which crystallises in silky, yellow needles, m. p. 164—165°.

Benzene-β-azoxycresol, $NPh\!:\!NO\cdot C_6H_3Me\cdot OH$, crystallises in lustrous, yellow needles, m. p. 70—72°; its yellow *benzoyl* derivative has m. p. about 56°, and its *acetyl* derivative was obtained only as a dense, non-crystallising oil.

Benzene-β-azoxynitrocresol, $NPh\!:\!NO\cdot C_6H_2Me(OH)\cdot NO_2$, forms yellow, acicular prisms, m. p. 117—119°, and yields aniline when reduced with tin and hydrochloric acid.

Benzene-β-azoxybromocresol, $NPh\!:\!NO\cdot C_6H_2MeBr\cdot OH$, forms chestnut-yellow, silky needles, m. p. 117°.

p-*Bromobenzene-β-azoxybromocresol*, $C_6H_4Br\cdot N\!:\!NO\cdot C_6H_2MeBr\cdot OH$, crystallises in golden-yellow, silky needles, m. p. 166—167°, is turned scarlet and dissolved by alkali hydroxide solution, and yields bromoaniline and bromoaminocresol (cf. Thiele and Eichwede, A., 1900, i, 501) on reduction. T. H. P.

NN′-Dimethylenesulphurous Acid-3 : 3′-diamino-4 : 4′-dihydroxyazobenzene. W. G. CHRISTIANSEN (*J. Amer. Chem. Soc.*, 1924, **46**, 497—503).—NN′-*Dimethylenesulphurous acid*-3 : 3′-*diamino*-4 : 4′-*dihydroxyazobenzene*, $C_{14}H_{16}O_8N_4S_2$, was isolated by the addition of formaldehyde and sodium bisulphite to the solution of the dihydrochloride of the 3 : 3′-diamino-4 : 4′-dihydroxyazobenzene prepared by the reduction of the corresponding nitro compound in an atmosphere of carbon dioxide. The *sodium*, *magnesium*, and *barium* salts are described. Contrary to expectations, the substance was physiologically inactive. A. B. S.

Absorption Spectra of certain Derivatives of *p*-Cymene. W. C. HOLMES (*J. Amer. Chem. Soc.*, 1924, **46**, 631—635).—The general effect of introducing methyl and *iso*propyl groups into a number of azo dyes of the benzene series is to shift the absorption band towards a region of longer wave-length, the displacement of the maximum being about 10 $\mu\mu$.

Introduction of the *iso*propyl group into Victoria green (malachite green) in the non-aminated nucleus in the *p*-position to the methane carbon atom produces a converging displacement of the two absorption bands in the visible spectrum. Both bands gradually disappear in sulphuric acid solution, and give rise to a new band, that of the *di*-acid salt, in the same spectral region as the second band of the neutral solution. The absorption bands of phenolsulphonephthalein and the homologue containing the *iso*propyl group in the sulphonated residue are practically identical, and absorption measurements in buffered solutions show that as p_H is lowered the transition between the absorption forms characteristic of alkaline and neutral solutions occurs more rapidly with the higher homologue than with the parent substance. S. K. T.

Azo Dyes from *m*-Methylethylbenzene. A. MAILHE (*Bull. Soc. chim.*, 1924, **35**, 382—383).—The following dyes have been prepared from 6-amino-1-methyl-3-ethylbenzene (cf. A., 1921, i, 661): 2-*methyl*-4-*ethyl*-4′-*hydroxyazobenzene*, a brown powder; 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthol*, a red powder; 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthylamine*, a maroon powder; 1-*methyl*-3-*ethylbenzene*-6-*azo*-α-*naphthylamine*, a greenish mass; 1-*methyl*-3-*ethylbenzene*-6-*azodimethylaniline*, a brown powder; from Schäffer salt, 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthol*-6-*sulphonic acid*, dark brown, dyeing maroon on silk; from R-salt, 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthol*-3 : 6-*disulphonic acid*, a red powder, dyeing silk a fast ponceau; from crocein acid, 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthol*-8-*sulphonic acid*, a maroon powder, giving maroon shades on silk. From G-salt, 1-*methyl*-3-*ethylbenzene*-6-*azo*-β-*naphthol*-6 : 8-*disulphonic acid*, dark yellow powder, dyeing maroon shades on silk; and from H-acid, 1-*methyl*-3-*ethylbenzene*-6-*azo*-8-*amino*-α-*naphthol*-3 : 5-*disulphonic acid*, reddish-scarlet, giving fast reddish-ponceau shades on silk. R. B.

Colour and Constitution. I. Effect of Isomerism on the Colour of certain Azo Dyes. M. L. CROSSLEY and P. V. RESENVELT (*Ind. Eng. Chem.*, 1924, **16**, 271—273).—Sodium benzeneazo-β-naphthol-6-sulphonate is a reddish-orange dye. If the sulphonic group passes to positions 7 and 8, the colour becomes progressively more yellow. The 3 : 6-disulphonic acid salt is more red, the 6 : 8-disulphonic acid salt more yellow than any of the monosulphonates. Further systematic colour modifications are caused by substitution within the benzene ring. There is also a great difference between the reactivities of the two β-naphtholdisulphonic acids, the presence of the sulphonic group in position 8 appearing to reduce the reactivity of the hydrogen in position 1, by neutralising the effect of the adjacent hydroxyl group. These facts are discussed in terms of the "force-field" and additive theories of chemical reactions. The relation between the effect on colour and the effect on reactivity of the position of the sulphonic group is held to be significant. [Cf. *B.*, 1924, 368.] C. I.

***m*-Nitrocinnamic Acid Hydrazide and its Behaviour with Nitrous Acid.** T. CURTIUS and P. A. BLEICHER (*J. pr. Chem.*, 1924, [ii], **107**, 86—98; cf. A., 1909, i, 838; 1911, i, 682, 814).—The action of hydrazine hydrate on ethyl *m*-nitrocinnamate gives, in addition to the main product of the reaction, m-*nitrocinnamic acid hydrazide*, $NO_2\cdot C_6H_4\cdot CH:CH\cdot CO\cdot NH\cdot NH_2$ (bright yellow, anisotropic plates, m. p. 139°), an isomeric substance, bright yellow needles, m. p. 198°, which with nitrous acid yields a true azide (see following abstract). *m*-Nitrocinnamic acid hydrazide when treated with iodine and sodium hydrogen carbonate in alcoholic solution is converted into a *dihydrazide*,

$$(NO_2\cdot C_6H_4\cdot CH:CH\cdot CO\cdot NH\cdot)_2,$$

pale yellow, prismatic needles, m. p. 279° (decomp.). The *hydrochloride*, tablets, m. p. 212° (decomp.), with benzaldehyde gives *benzylidene*-m-*nitrocinnamic acid hydrazide*, minute needles, m. p. 206·5°, whilst benzoyl chloride yields *benzoyl*-m-*nitrocinnamic acid hydrazide*, $NO_2\cdot C_6H_4\cdot CH:CH\cdot CO\cdot NH\cdot NHBz$, prisms, m. p. 185·5°. With ethyl acetoacetate, *m*-nitrocinnamic acid hydrazide yields the *compound*, $NO_2\cdot C_6H_4\cdot CH:CH\cdot CO\cdot NH\cdot N:CMe\cdot CO_2Et$, white, fibrous needles, m. p. 67·5°, and with phenylthiocarbimide m-*nitrocinnamylphenylthiosemicarbazide*,

$$NO_2\cdot C_6H_4\cdot CH:CH\cdot CO\cdot NH\cdot NH\cdot CS\cdot NHPh,$$

pale yellow plates, m. p. 147°. Sodium nitrite readily converts the hydrochloride into 1-*nitroso*-5-m-*nitrophenyl*-3-*pyrazolidine*, yellow, prismatic plates, m. p. 108° (*ammonium*, *silver*, and *barium* salts described). The silver salt on treatment with ethereal ethyl iodide gives 1-*nitroso*-2-*ethyl*-5-*m*-*nitrophenyl*-3-*pyrazolidine*, greyish plates, m. p. 168°. The ammonium salt of 1-nitroso-5-*m*-nitrophenyl-3-pyrazolidine gives a *picrate*, m. p. 107—108°. The action of bromine on 1-nitroso-5-*m*-nitrophenyl-3-pyrazolidine in acetic acid solution gives 4-*bromo*-3-m-*nitrophenyl*-5-*pyrazoline*, yellow plates, m. p. 188°, only one bromine atom entering the ring, whereas the action of bromine on 1-nitroso-5-phenyl-3-pyrazolidine gives 4 : 4-dibromo-3-phenyl-5-pyrazolone. On boiling with dilute sulphuric acid, the 1-nitroso-5-*m*-nitrophenyl-3-pyrazolidine is converted into 3-m-*nitrophenyl*-4-*isonitroso*-5-*pyrazoline*, orange, silky needles, m. p. 217°.

The isomeric *m*-nitrocinnamic acid hydrazide, of m. p. 198°, gives a *benzylidene* derivative, m. p. 184°, and a *hydrochloride*, m. p. 256° (decomp.). R. B.

m-Nitrocinnamic Acid Azide. T. CURTIUS and E. KENNGOTT (*J. pr. Chem.*, 1924, [ii], **107**, 99—102).—The isomeric *m*-nitrocinnamic acid hydrazide of m. p. 198° formed as a by-product in the action of hydrazine hydrate on *m*-nitrocinnamic ester (see preceding abstract) on treatment with nitrous acid gives m-*nitrocinnamic acid azide*, $NO_2\cdot C_6H_4\cdot CH{:}CH\cdot CO\cdot N_3$, colourless, rhombic crystals (m. p. 117—118°, with evolution of gas), which are converted into *m*-nitrocinnamic acid when warmed with alkali. When warmed with *p*-toluidine in alcoholic solution, the azide gives *p*-tolyl *m*-nitrostyrylcarbamide,

$$NO_2\cdot C_6H_4\cdot CH{:}CH\cdot HN\cdot CO\cdot NH\cdot C_6H_4\cdot CH_3,$$

bright yellow needles, m. p. 213—214°. Boiling with water converts the azide into nitrogen, carbon dioxide, and a colourless carbamide (?), m. p. 186°. Boiling with methyl alcohol gives the known methyl *m*-nitrostyrylcarbamate,

$$NO_2\cdot C_6H_4\cdot CH{:}CH\cdot NH\cdot CO\cdot OMe,$$

yellow needles, m. p. 140°, which when boiled with dilute sulphuric acid give *m*-nitrophenylacetaldehyde. The interconversion of *m*-nitrocinnamic acid hydrazide, m. p. 139°, and the isomeric compound, m. p. 198°, can be effected either by heating above the melting point or by warming in alcoholic solution or under pressure. R. B.

Salts with *para*-, *ortho*-, and *meta*-Quinonoid Structure. V. R. CIUSA and G. RASTELLI (*Gazzetta*, 1924, **54**, 72—78; cf. A., 1922, i, 1073).—*p*-Nitrophenylmethylhydrazones,

$$CHR{:}N\cdot NMe\cdot C_6H_4\cdot NO_2,$$

of the following aldehydes have been prepared: *Formaldehyde*, dark yellow crystals, m. p. 153°, separating even from solutions containing the aldehyde in the proportion 1 : 10,000; *acetaldehyde*, yellow needles, m. p. 91°; *butyraldehyde*, yellow crystals, m. p. 05° (?); p-*tolualdehyde*, yellow, tabular crystals, m. p. 150°; o-*nitrobenzaldehyde*, orange-yellow, acicular crystals, m. p. 211—212°; m-*nitrobenzaldehyde*, lemon-yellow crystals, m. p. 250°; p-*nitrobenzaldehyde*, orange-yellow crystals, m. p. 249—250°; *cuminaldehyde*, yellow crystals with violet reflection, m. p. 112°; *dimethylaminobenzaldehyde*, bright red needles, m. p. 193°; *cinnamaldehyde*, dark yellow needles, m. p. 153—154°; *salicylaldehyde*, dark yellow needles, m. p. 150°; p-*hydroxybenzaldehyde*, red crystals, m. p. 204°; *anisaldehyde*, small, yellow crystals, m. p. 155—156°; *protocatechualdehyde*, bright red crystals, m. p. 218°; *vanillin*, m. p. [illegible], existing in yellow and red chromoisomeric modifications; [illegible], yellow crystals, m. p. 190—191°; 2 : 4-*dihydroxy*-[illegible], deep red crystals, m. p. 265°; 2-*hydroxy*-4-*methoxy*-

benzaldehyde, lustrous, yellow needles, m. p. 148°, existing also in a red modification; *furfuraldehyde*, orange-yellow, crystalline plates, m. p. 171°; *pyrrolealdehyde*, bright red, acicular crystals, m. p. 177°; *acetone*, silky, yellow needles, m. p. 54°; cyclo*hexanone*, yellow crystals, m. p. 186°. The *mono*-p-*nitrophenylmethylhydrazone* of *diacetyl* forms brownish-yellow needles, m. p. 154°, that of *acetylacetone*, lustrous, orange needles, m. p. 128°, and that of *acetonylacetone*, yellow needles, m. p. 130°.

Benzaldehyde-p-*nitrophenylethylhydrazone*,

$$CHPh{:}N{\cdot}NEt{\cdot}C_6H_4{\cdot}NO_2,$$

obtained by the action of ethyl iodide on the potassium salt of benzaldehyde-*p*-nitrophenylhydrazone, forms large, yellow crystals, m. p. 134°. When boiled with hydrochloric acid it yields as-p-*nitrophenylethylhydrazine*, $NH_2{\cdot}NEt{\cdot}C_6H_4{\cdot}NO_2$, which crystallises in lustrous, yellow leaflets, m. p. 74°, and energetically reduces Fehling's and ammoniacal silver solutions. p-*Nitrobenzaldehyde*-p-*nitrophenylethylhydrazone* crystallises in yellow needles, m. p. 267°.

Benzaldehyde-p-*nitrophenylbenzylhydrazone*, $C_{20}H_{17}O_2N_3$, prepared from benzyl chloride and the potassium derivative of benzaldehyde-*p*-nitrophenylhydrazone, forms lustrous, yellow, laminar crystals, m. p. 158°, and as-p-*nitrophenylbenzylhydrazine*, $C_{13}H_{13}O_2N_3$, which reduces Fehling's solution and ammoniacal silver solution, yellow needles, m. p. 121°. T. H. P.

[**Aromatic Arsenious Acids.**] A. ALBERT (U.S. Pat. 1472778).—Nitroaminohydroxyacetophenone, when diazotised and treated in alkaline solution with sodium arsenite, yields nitrohydroxyacetylphenylarsinic acid, $CH_3{\cdot}CO{\cdot}C_6H_2(OH)(NO_2){\cdot}AsO_3H_2$, needles, m. p. about 200°. Similarly, *p*-aminobenzophenone yields benzoylphenylarsinic acid, m. p. 195—197°, diaminobenzophenone yields the diarsinic acid compound, m. p. 260°, and *p*-aminobenzaldehyde yields *p*-aldehydophenylarsinic acid.

CHEMICAL ABSTRACTS.

Tin Di*cyclo*hexyl, Hexa*cyclo*hexyldistannane, and other *cyclo*Hexyl Compounds of Tin. E. KRAUSE and R. POHLAND (*Ber.*, 1924, 57, [*B*], 532—544).—An extension of the work on the organo-metallic derivatives of tin (Krause and Becker, A., 1920, i, 340) to the *cyclo*hexyl series. The *cyclo*hexyl bromide used had b. p. 52·5°/13·5 mm., $d_4^{16\cdot8}$ (vac.) 1·3348, $n_D^{16\cdot8}$ 1·49758, whereas *cyclo*hexyl chloride had b. p. 141°/760 mm., $d_4^{20\cdot3}$ 1·0000, $n_D^{20\cdot3}$ 1·46264.

Tin tetra*cyclo*hexyl, $Sn(C_6H_{11})_4$ (cf. Grüttner, A., 1915, i, 335), is prepared by the gradual addition of a solution of stannic chloride in benzene to a solution of magnesium *cyclo*hexyl bromide or chloride in a mixture of ether and benzene. The product is a mixture of tin tetra*cyclo*hexyl, hexa*cyclo*hexyldistannane, and halogenated substances which cannot be separated into its components by crystallisation except with great loss of material; it is therefore converted into the monobromide (see later), which is readily purified and subsequently transformed by magnesium *cyclo*hexyl bromide into the tetra derivative, which crystallises in colourless, quadratic platelets, m. p. 263—264° after slight previous softening (Grüttner gives m. p. 248°).

*Tin di*cyclo*hexyl*, $Sn(C_6H_{11})_2$, prepared from stannous chloride and magnesium *cyclo*hexyl bromide, is an intensely yellow, voluminous powder, melting to a red liquid at 176—178° after darkening at 130°. It is stable in an atmosphere of nitrogen, but gradually oxidises in air, particularly under the influence of light. It is converted by *cyclo*hexyl bromide at 140° into tin di*cyclo*hexyl dibromide. Attempts to convert it into hexa*cyclo*hexyldistannane by means of magnesium *cyclo*hexyl bromide (cf. A., 1920, i, 341) were unsuccessful.

*Hexa*cyclo*hexyldistannane*, $(C_6H_{11})_3Sn\cdot Sn(C_6H_{11})_3$, is prepared by the action of sodium on a solution of tin tri*cyclo*hexyl bromide in boiling xylene. It forms colourless, hexagonal platelets, stable towards light and air, decomp. slightly above 300°. Its molecular weight in concentrated solution corresponds with the formula $[Sn(C_6H_{11})_3]_2$, whereas the simpler molecular form appears to be present in more dilute solution.

*Tin tri*cyclo*hexyl bromide*, $(C_6H_{11})_3SnBr$, prepared from the crude product of the action of magnesium *cyclo*hexyl halide on stannic chloride (see above) by means of bromine in the presence of chloroform or carbon tetrachloride, crystallises in long, colourless prisms, m. p. 77°, decomp. about 280°. The corresponding *iodide* forms colourless, hexagonal plates, m. p. 65°, decomp. about 290°. The *fluoride* forms hexagonal prisms, decomp. about 305°. *Tin tri*cyclo*hexyl hydroxide*, colourless, hexagonal crystals, m. p. 220—222°, is prepared by shaking an ethereal solution of the bromide with an excess of potassium hydroxide solution (15%); when dehydrated, it yields the oxide, $(C_6H_{11})_3Sn\cdot O\cdot Sn(C_6H_{11})_3$. (Tin triphenyl hydroxide, long, hexagonal prisms, m. p. 119—120°, appears to be dehydrated similarly to the *oxide*, $Ph_3Sn\cdot O\cdot SnPh_3$; there is no evidence of the formation of different hydrates.) *Tin tri*cyclo*hexyl chloride*, obtained from the hydroxide and dilute hydrochloric acid, forms long, prismatic rodlets, m. p. 129—130°, decomp. about 286°; with ammonia it appears to yield the *compound*, $(C_6H_{11})_3SnCl,2NH_3$, m. p. 128° (decomp.).

Tin di*cyclo*hexyl dibromide, m. p. 58° (cf. Grüttner, *loc. cit.*), is hydrolysed to the corresponding *dihydroxide* (or *oxide*), a colourless, amorphous powder, m. p. 291° (decomp.) after darkening at 280° and softening at 287°. The corresponding *dichloride*, colourless, asbestos-like needles, m. p. 88—89°, decomp. about 220°, the *difluoride*, a colourless, microcrystalline powder, m. p. 278° after previous softening, and the di-iodide, a colourless, crystalline powder, m. p. 42° (Grüttner, *loc. cit.*, gives m. p. 145°), are described.

The following compounds are prepared by the action of a large excess of the requisite Grignard compound on tin tri*cyclo*hexyl bromide in ethereal solution: *Tin tri*cyclo*hexylmethyl*, $(C_6H_{11})_3SnMe$, a colourless, viscous liquid, b. p. 221°/15 mm., $d_4^{20\cdot7}$ (vac.) 1·1949, $n_D^{20\cdot7}$ 1·53979. *Tin tri*cyclo*hexylethyl*, a very viscous liquid, b. p. [illegible]—228°/15 mm. (partial decomp.), $d_4^{15\cdot9}$ (vac.) 1·1875, $n_D^{15\cdot9}$ 1·53953. [illegible]cyclo*hexyl*, colourless, microscopic crystals, m. p. 191—

192°; 0·65 g. dissolves in 100 g. of ethyl alcohol at 30·4°. *Tin* p-*tolyltri*cyclo*hexyl*, prismatic rodlets, m. p. 111°, which dissolves in ethyl alcohol to the extent of 0·70 g. in 100 g. at 30·4°. *Tin triphenyl*cyclo*hexyl*, colourless needles, m. p. 131—132°, is obtained from tin triphenyl chloride and magnesium *cyclo*hexyl bromide.
H. W.

Peptisation of Gelatin by Mixed Liquids. E. W. J. Mardles (*Biochem. J.*, 1924, **18**, 215—230).—The peptisation of gelatin in mixtures of various solvents has been studied. The solubility of gelatin is greater in mixed liquids than the average value, and under some conditions the solvent power of water can be increased, or not appreciably diminished, by the addition of a non-solvent such as pyridine, glycerol, alcohol, etc. The theory of this phenomenon is discussed. S. S. Z.

Constitution of Proteins. N. Troensegaard and I. Schmidt (*Z. physiol. Chem.*, 1924, **133**, 116—125).—The authors bring forward evidence which they claim lends further support to the view that the protein molecule consists mostly of pyrrole derivatives containing oxygen. Acetylated gliadin, gelatin, and proteolic acid from gliadin were degraded by reduction into various fractions which showed properties characteristic of heterocyclic compounds.
S. S. Z.

Proteins of Oats. H. Lüers and M. Siegert.—(See i, 597.)

Biochemistry.

Influence of Intravenous Injection of Protein on the Respiratory Exchange. E. Amstad (*Biochem. Z.*, 1924, **145**, 168—177).—In dogs, the average normal output of carbon dioxide per kilogram per minute is 9·5585 c.c. and the oxygen intake is 12·94 c.c. Intravenous injection of Ringer solution has a very slight effect in increasing the respiratory exchange; injection of foreign serum (horse) protein first lowers the exchange by 30% of its normal value, but later it rises above normal to the same extent, whilst injection of the serum-proteins of the dog itself produces the same effect as Ringer solution. J. P.

Physiology of Glands. LVIII. Possible Presence of Toxic Substances in the Sera of Thyroid- and Parathyroid-ectomised Animals in Relation to the Respiratory Exchange. L. Asher and K. Jino (*Biochem. Z.*, 1924, **145**, 105—115).—Intraperitoneal injection into rats of 1 to 2 c.c. of the sera of normal or thyroidectomised dogs increases the respiratory exchange, whilst sera from parathyroidectomised dogs with tetany lowers the respiratory exchange. It is concluded that whilst toxic substances are absent in the former case they may be present in the latter. J. P.

Physiology of Glands. LX. Respiratory Exchange of Normal and Splenectomised Rats. L. ASHER and Y. TAKAHASHI (*Biochem. Z.*, 1924, **145**, 130—153).—In general, removal of the spleen from rats diminishes the respiratory exchange, and increases the nitrogen excretion and the response to thyroid feeding as compared with the normal animals. The presence or absence of iron in the dietary has no influence on the respiratory exchange effect. Rats from which the spleen has been removed show a greater susceptibility to lack of oxygen than that shown by normal rats. The results are interpreted in favour of the view that the spleen and the thyroid are mutually antagonistic. J. P.

Physiology of Glands. LXI. Comparison of the Oxygen Consumption of Surviving Excised Mammalian Organs in the Normal Condition and after Thyroid Feeding. L. ASHER and A. ROHRER (*Biochem. Z.*, 1924, **145**, 154—167).—The isolated surviving liver, kidney, and muscle of mice which had been fed on thyroid consumed more oxygen than the same organs from normal animals. The respective figures found for 1 g. of each tissue per hour are: 639 and 784 c.mm., 818 and 941 c.mm., 791 and 985 c.mm. J. P.

Collection and Preservation of Blood Samples for Determination of Carbon Monoxide. R. R. SAYERS, H. R. O'BRIEN, G. W. JONES, and W. P. YANT (*U.S. Public Health Repts.*, 1923, 2005—2011. Reprint No. 863).—A modified Keidel tube method is described for the collection, transport, and storage of samples of 10—15 c.c. of blood in cases of carbon monoxide poisoning. A small vial, well-stoppered with a cork, will serve satisfactorily in emergency. For the inhibition of coagulation, sodium citrate (0·4 to 0·8 %) proved inefficient, sodium or potassium oxalate (0·2%) caused some change in the blood with a slight alteration in the carbon monoxide content, whilst sodium fluoride (0·3%) is recommended as being free from these objections. E. M. C.

Elimination of Carbon Monoxide from Blood by Treatment with Air, with Oxygen, and with a Mixture of Carbon Dioxide and Oxygen. R. R. SAYERS and W. P. YANT (*U.S. Public Health Repts.*, 1923, 2053—2074. Reprint No. 865).—Analyses of blood samples, made in carefully controlled experiments on three subjects, showed that the elimination of carbon monoxide depends on the percentage of oxygen in the air breathed and also on the rate and depth of respiration. Pure oxygen was about four times as efficient as ordinary air, whilst a mixture of oxygen containing 8 to 10% of carbon dioxide was about five to six times as efficient. E. M. C.

Seasonal Changes in the Gases and Sugar of the Blood, and the Nitrogen Distribution in the Blood and Urine of the Alligator. A. HOPPING (*Amer. J. Physiol.*, 1923, **66**, 145—163).—[illegible] capacity of the blood is highest (15·3) in March, and [illegible] in May and June; the oxygen content of the venous blood is lowest (1·8) in May and June and highest (11·0) in January and February. The carbon dioxide capacity and content are higher in spring than in summer or winter. Blood-sugar is high (0·095%) in spring and very low (0·0296%) in late autumn. The main nitrogenous constituent of the urine is ammonia; uric acid is present in the blood and urine in small amounts only.

CHEMICAL ABSTRACTS.

Influence of Oxygen Content on the Hydrogen-ion Concentration of the Blood. J. HOLLÓ and S. WEISS (*Biochem. Z.*, 1924, **145**, 10—13).—The p_H of human oxalated venous blood kept at a constant carbon dioxide content and oxygenated, is lowered by 0·03—0·06.

J. P.

Experimental Tetany. III. Alkalosis and Acidosis. IV. Hydrogen-ion Concentration of the Blood. V. Alveolar Carbon Dioxide Tension. E. W. H. CRUICKSHANK (*Biochem. J.*, 1924, **18**, 47—62).—A change in the acid–base balance in parathyroid tetany, with the production of a condition of alkalosis, is observed in the primary or quiescent stage and is due to CO_2 deficit. With the development of acute tetany, this condition is changed into one of acidosis by the continuous loss of $BHCO_3$ and increase in H_2CO_3. The reaction of the blood as determined from CO_2 dissociation curves changes very slightly, the p_H increasing above normal for the animal by an average of 0·154 during the stage of alkalosis and falling with the introduction of the stage of acidosis. The alveolar CO_2 may fall as low as 1·975%, but with the continued loss of base there is a tendency for it to return towards the normal.

S. S. Z.

Chemical Pathology of Pyloric Occlusion in Relation to Tetany. Chloride, Carbon Dioxide, and Urea Concentrations in the Blood. H. A. MURRAY, jun. (*Arch. Surgery*, 1923, **7**, 166—196).—With stenosis of the pylorus, hydrogen chloride cannot pass into the intestines and be absorbed. It is expelled by vomiting or by gastric lavage. The result is a disturbance in the acid–base balance of the blood and tissues. The blood shows increased carbon dioxide and urea, and decreased chlorine. The most abnormal values found were: CO_2, 107% by vol.; Cl, 2·5 g. per l., and urea, 334 mg. per 100 c.c. of blood. There is a relation between these changes and the tetany which develops in severe cases. It is highly probable that nerve irritation is increased by a fall in the hydrogen-ion concentration of the blood or the sodium : calcium ratio.

CHEMICAL ABSTRACTS.

Nature of the Red Blood-corpuscle. A. GOUGH (*Biochem. J.*, 1924, **18**, 202—214).—The red corpuscle is a fluid droplet the contents of which form a hydrophile colloidal system. The continuous phase (salts and water) constitutes one-third, the dispersed phase (hæmoglobin salts and water) two-thirds of this system. The surface film contains lipoids in a solid state, and all varieties of hæmolysis can be explained as due to disintegration of the envelope of the corpuscle. Crenation is due to protrusion through weak areas in the envelope of the corpuscle. The characteristic shape of the corpuscle is due to tension of liquid surfaces tending to cause a spherical shape and to the repulsive forces between the dispersed particles of the corpuscular contents. S. S. Z.

Adsorption of Protein Degradation Products by Erythrocytes. N. Griasnov (*Biochem. Z.*, 1924, **145**, 63—65).—Contrary to the results of Sbarsky (A., 1923, i, 1252), biological methods of determining fixation reveal no adsorption of diphtheria toxin by erythrocytes *in vitro*. The disappearance of nitrite observed by Sbarsky and attributed by him to adsorption of protein degradation products is ascribed to oxidation by oxyhæmoglobin derived from hæmolysed erythrocytes. J. P.

Hæmoglobin and Methæmoglobin as Oxidative Catalysts. M. E. Robinson.—(See this vol., ii, 320.)

Lævulose in the Blood of the Human Fœtus. A. P. Orr (*Biochem. J.*, 1924, **18**, 171—172).—Human fœtal blood gives the Selivanov reaction, which shows the presence of lævulose. This sugar can also be demonstrated in the blood of the kid immediately after birth. S. S. Z.

Syphilis. V.—VIII. Arsenic Content of the Blood and Spinal Fluid after Neosalvarsan and Salvarsan Treatment. J. A. Fordyce, I. Rosen, and C. N. Myers (*Amer. J. Syphilis*, 1923, **7**, 444—559).—With neosalvarsan, arsenic was found, in quantities of 0·6—83·6 mg. per 100 g. of dried spinal fluid, at some time during the treatment in 22% of the cases; with salvarsan, after combined intravenous and intraspinal injections, arsenic was present in 88% of the fluids up to 73 mg., whereas after injection and drainage, arsenic was present up to 54·3 mg. in 83% of the specimens. The maximum amount of arsenic is present in the blood immediately after intravenous injection of silver salvarsan, but it quickly becomes localised outside of the circulating blood.

Chemical Abstracts.

Hydrogen-ion Concentration of Gastric Contents of Infants. F. L. Babbott, jun., J. A. Johnston, C. A. Haskins, and A. T. Shohl (*Amer. J. Diseases Children*, 1923, **26**, 475—485).—The normal range of the p_H of the gastric contents on the milk test meal at the end of an hour is p_H 3·2—5·0, with 76% of the readings between p_H 3·9 and p_H 4·6. The error of determining acidity of gastric contents from samples rather than from the entire contents is p_H 0·4. The acidity increases with increase in time. The previous type of feeding has no effect on the test meal. Acid production and hydrogen-ion concentration increase with increase of age. A fourfold increase of the concentration of the test meal decreases the hydrogen-ion concentration. A twofold increase of the amount of the test meal causes a stimulation of acid secretion, but a lessened [illegible]. The greater the gastric acidity, the more rapidly the [illegible]

Chemical Abstracts.

Metabolism of Carbohydrates. III. Absorption of Glucose, Fructose, and Galactose from the Small Intestine. J. A. Hewett (*Biochem. J.*, 1924, **18**, 161—170).—Glucose, fructose, and galactose are absorbed from hypotonic solution from the small intestine, the rates of absorption decreasing in the order named. However, when the epithelial lining is destroyed, all three sugars are absorbed at the same rate. The results cannot be explained by osmosis or diffusion only. S. S. Z.

Production of Hypoglycæmia in Experimental Derangements of the Liver. M. Bodansky (*Amer. J. Physiol.*, 1923, **66**, 375—379).—Hyperglycæmia is the initial effect of severe liver damage (severe chloroform or phosphorus poisoning). Subsequently this effect disappears and the blood-sugar falls to subnormal levels. Chloroform and phosphorus are general protoplasmic poisons, and death resulting from such acute poisoning is not due entirely to functional damage of the liver. Chemical Abstracts.

Physiology of Glands. LIX. Influence of Compensation on the Glycosuric Action of Subcutaneous Adrenaline Injections. L. Asher and R. Tsukamoto (*Biochem. Z.*, 1924, **145**, 116—129).—The adrenaline glycosuria of thyroid-fed dogs which react strongly to the treatment, is, in some cases, more rapid but less intense than that of normal animals, but in others the glycosuria may be more intense than that of the normals. The results are explained on the basis of a double functioning of the thyroid hormone. Removal of blood or transfusion of a Ringer gelatin solution after bleeding produces a diminution in the response to adrenaline. J. P.

Preparation of Insulin. Alkaline Extraction of Pancreas. H. W. Dudley and W. W. Starling (*Biochem. J.*, 1924, **18**, 147—150).—By the addition of sodium bicarbonate to the mixture of minced pancreas and alcohol the yield of insulin is increased nearly fivefold. An improved technique for the preparation of insulin hydrochloride through the picrate is also described, whereby at least 90% of the impurities in crude insulin can be removed. 0·2 Mg. of this preparation was found to be a "rabbit unit." S. S. Z.

Mode of Oxidation of Fatty Acids with Branched Chains. III. The Fate in the Body of α-Methylcinnamic Acid, β-Phenyl*iso*butyric Acid, and γ-Phenyl*iso*valeric Acid. H. D. Kay and H. S. Raper (*Biochem. J.*, 1924, **18**, 153—160).—β-Phenyl*iso*butyric acid on oxidation in the body yields benzoic acid. The yield was 77% of the theoretical, assuming that β-oxidation alone had taken place. α-Methylcinnamic acid, which has been isolated as an intermediate product, also yields benzoic acid, but only to the extent of 33% of the amount expected if β-oxidation alone had taken place. No intermediate product could be isolated in this case. No difference was observed in the ease of oxidation in the body of the two isomorphous forms of α-methylcinnamic acid. γ-Phenyl*iso*valeric acid gives rise to phenylacetic acid on oxidation in the body; the yield was not more than 50% of the amount expected if β-oxidation alone had taken place. S. S. Z.

Odd-carbon Fats in the Treatment of Diabetic Ketosis. M. Kahn (*Amer. J. Med. Sci.*, 1923, **166**, 826—833).—An odd-carbon fatty acid has been synthesised (the acid group of stearic acid is replaced by an organic radical and on oxidation the C_{17} acid is produced, which is united with glycerol) which is absorbed to about 90% and is catabolysed without the production of ketones.

Chemical Abstracts.

Metabolism of Milch Cows suffering from Acetonæmia. B. Sjollema and J. E. van der Zande (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, **26**, 666—668).—Analyses of blood, urine, and milk from cows suffering from acetonæmia show that waste of body fat takes place on a large scale, often about 1 kg. per diem. Lipæmia, glucosuria, and hyperglycæmia do not occur. The total quantity of acetone compounds in the urine may amount to about 120 g. per day. The cholesterol content of the blood is 50% to 100% higher than normal; sometimes it is even higher. The alkali reserve decreases. J. F. S.

Possibility of Influencing Decomposition of Albumin in the Body by Feeding Individual Amino-acids. R. W. Seuffert (*Z. Biol.*, 1924, **80**, 381—404).—Experiments on dogs receiving a diet containing insufficient protein show that whilst the feeding of individual amino-acids of the simplest type or an incomplete mixture of such acids never leads to an increase of body nitrogen or even to nitrogen equilibrium, an appreciable reduction in the daily loss of nitrogen from the body can be achieved by this means, which cannot be accounted for as merely the result of the additional calories brought to the diet by the amino-acids added. These results are checked and confirmed by a consideration of the daily loss of sulphur from the body with and without the addition of amino-acids to the diet. H. C. R.

Choline as a Precursor of Guanidine. Decrease in the Amount of Choline of the Hen's Egg during Incubation. J. S. Sharpe (*Biochem. J.*, 1924, **18**, 151—152).—There is a decrease in choline content of the hen's egg as incubation proceeds. It has been previously shown by Burns that the guanidine content increases during this period. The author suggests that choline is a possible source of guanidine in the animal body. S. S. Z.

Synthesis of Hippuric Acid in the Surviving Kidney of Various Animals and of Man. I. Snapper, A. Grünbaum, and J. Neuberg (*Biochem. Z.*, 1924, **145**, 40—46).—Perfusion of the isolated surviving kidney of the dog, sheep, pig, and man, with blood containing sodium benzoate and glycine, results in the synthesis of hippuric acid. J. P.

Sulphur Metabolism of the Dog. I. Synthesis of Ethereal [illegible] T. S. Hele (*Biochem. J.*, 1924, **18**, 110—119).—[illegible], sodium hydrogen sulphite, and cystine are partly

excreted as ethereal sulphate by the dog when administered by the mouth together with guaiacol carbonate. The sodium sulphate is utilised as readily as cystine or as sodium hydrogen sulphite.
S. S. Z.

Calcium Fixation by Animal Tissues. R. E. Liesegang (*Biochem. Z.*, 1924, **145**, 96—97).—A criticism of the conclusions of Freudenberg and György (this vol., i, 242). J. P.

Mineral Metabolism of the Lactating and Dry Goat. C. H. Hunt, A. R. Winter, J. A. Schultz, and R. C. Miller (*Amer. J. Physiol.*, 1923, **66**, 349—362).—Balances were determined for sodium, potassium, calcium, magnesium, sulphur, chlorine, phosphorus, and nitrogen in dry and lactating goats on various diets, the mineral metabolism being found, in general, to be similar to that of the cow. The calcium and chlorine content of goat's milk is higher than of cow's milk. There is evidence that the calcium in green plants may be more highly dispersed, and hence better assimilated than that of dried feeds. Chemical Abstracts.

Nitrogen and Mineral Salt Metabolism in Avitaminosis. N. Hirabayashi (*Biochem. Z.*, 1924, **145**, 18—31).—In the avitaminosed dog, the body-weight may increase during the first few weeks, usually with increasing nitrogen retention, although towards the end of this period the nitrogen excretion may show an increase. With increasing duration of avitaminosis, the disturbed gastro-intestinal functioning is reflected in diminished body-weight and nitrogen excretion, and in the late stages a temporary increase in the nitrogen retention may set in. The nitrogen excretion is not an indication of the breakdown of nitrogen compounds in the body, since the residual nitrogen of the blood progressively increases in avitaminosis. The phosphorus, calcium, and magnesium balances in avitaminosis are parallel to the diminution in protein metabolism.
J. P.

Properties of certain South African Oils with Respect to Their Content of Vitamin-*A*. E. M. Delf (*Biochem. J.*, 1924, **18**, 93—100).—Sesamé, mafurreira, and castor oils are deficient in vitamin-*A*. Two samples of seal oil have been found to possess considerable growth-promoting properties. Samples of crude whale oil are active inversely to the temperatures used in the extraction. Sperm whale oil obtained from the head is the least active, and that obtained from the blubber is the most active in growth-promoting. When rats are deficient in vitamin-*A*, the addition of vitamin-*C* has a more beneficial effect than when the supply of vitamin-*A* in the diet is adequate. S. S. Z.

Relation of Vitamin-*A* Potency of the Liver Oil to the Sexual Condition and Age of the Cod. S. S. Zilva, J. C. Drummond, and M. Graham (*Biochem. J.*, 1924, **18**, 178—181).—The sexual condition and age of the cod do not influence the vitamin-*A* potency of the liver oil. S. S. Z.

Feeding Experiments in Connexion with Vitamin-*A* and -*B*. V. Orange Juice as a Source of Vitamin-*B*. VI. Ophthalmia in Rats affected with Avitaminosis. VII. The Vitamin Content of Cod-liver Oil and Malt Extract. A. D. STAMMERS (*Biochem. J.*, 1924, **18**, 9—15).—A daily dose of 10 c.c. of orange juice does not contain sufficient vitamin-*B* to promote growth in rats. The susceptibility of rats to keratomalacia varies directly with the amount of vitamin-*A* in the diet. Adult animals are less susceptible. "Cod-liver oil and malt extract" contains sufficient vitamin-*A* and -*B* to provide the necessary stimulus to growth. S. S. Z.

Vitamins. I. L. MARCHLEWSKI and Z. WIEVZCHOWSKI (*Bull. Soc. Chim. biol.*, 1924, **6**, 40—43).—Vitamin-*B* is better extracted from bran by dilute aqueous hydrochloric acid (0·1%) than by alcohol. From this solution, after neutralisation and filtration, addition of an ammoniacal solution of silver nitrate produces a greenish-brown precipitate containing the vitamin. This is dissolved out by hydrochloric acid, and after evaporating to dryness in a vacuum, and dissolving in water, a solution of great potency is obtained. From this solution, on the addition of picric acid, a yellowish-orange compound is precipitated, which may be recrystallised from acetone. A brownish-yellow solution of the vitamin, which has a characteristic odour, is obtained on decomposition of the picrate by dilute hydrochloric acid, and removal of the picric acid with ether. W. O. K.

The Reaction Proposed by Jendrassik as Characteristic of Vitamin-*B*, and its Relation with the Phenolic Grouping. M. N. BEZSSONOFF (*Bull. Soc. Chim. biol.*, 1924, **6**, 35—39).—The solution of ferric chloride and potassium ferricyanide, said by Jendrassik (A., 1923, ii, 892) to turn blue in presence of vitamin-*B*, is turned blue also by *o*- and *p*-phenols. Jendrassik is not justified in his conclusion that vitamin-*B* does not contain a phenolic group. W. O. K.

Antiscorbutic Fraction of Lemon Juice. I. S. S. ZILVA (*Biochem. J.*, 1924, **18**, 182—185).—A great part of the solids of decitrated lemon juice consists of invert-sugar. It is possible to ferment the sugar and thus reduce the solids without appreciably altering the antiscorbutic activity of the solution. The remaining solids seem to consist of substances mainly of a nitrogenous character. Some chemical characteristics of the active fraction are given. S. S. Z.

Conservation of the Potency of Concentrated Antiscorbutic Preparations. II. S. S. ZILVA (*Biochem. J.*, 1924, **18**, 186—187).—Concentrated decitrated lemon juice retains its antiscorbutic potency for five months if stored in acid solution in ampoules in a vacuum. S. S. Z.

[illegible] and Fat-soluble Growth Catalysts (*D*-Vitamins). [illegible] (*Ark. Kemi, Min., Geol.*, 1923, **8**, No. 31, 1—10).—[illegible] pressed yeast and a brewery yeast, by extraction with water, dialysis through collodion membranes, concentration under a pressure of 1 mm., and precipitation by means of alcohol, the author has obtained preparations which effect very marked accelerations of fermentation either by living yeast or by washed dried yeast. With such preparations, however, there exists no parallelism between the influence on the growth of the yeast and that on the fermentation; moreover, no quantitative relationship is observable between the effects produced on the growth of yeast and of mice. In the light of these results the suggestion is made that the letter *D* be retained for growth factors but that D_r and D_m be used to denote the growth substance for rats or mice and for micro-organisms, respectively.

It is proposed further that the name vitamin be reserved exclusively for the following substances which act against definite vitamin-deficiency diseases: vitamin-*A* against rickets; vitamin-*B* against polyneuritis, and vitamin-*C* against scurvy. Substances which accelerate growth but may have nothing further in common with vitamins other than natural occurrence in low concentrations and certain properties relating to sorption, may be designated biocatalysts or growth-substances. In this way, the necessity of classifying Harden's co-zymase, hormones, etc., as vitamins is avoided.

As regards the effect on the growth of mice produced by cod-liver oil, at least one-fifth of the substances causing this effect is found to be transferable to aqueous-alcoholic or aqueous solution. The growth-substance obtained by extracting yeast with water is, however, removed to only a small extent from its concentrated aqueous solution when the latter is shaken with double its volume of a vitamin-free animal oil. T. H. P.

Separation of a Fat Pigment from Accompanying Fat. A. N. CURRIE (*Biochem. J.*, 1924, **18**, 231—234).—The fat is ground with lime and hydrolysed for 10 hours in an autoclave. The adipochrome goes mainly into the aqueous layer. The fatty acids are extracted with distilled water and the aqueous portions are combined and extracted with ether. The aqueous layer, which consists of pigment, salt, and glycerol, is acidified with 20% hydrogen chloride and extracted with ether. The adipochrome goes into the ether. S. S. Z.

Lipochrome of Adipose Tissue in Malignant Disease. A. N. CURRIE (*Biochem. J.*, 1924, **18**, 235—244).—The pigment is an unsaturated aliphatic hydrocarbon and is not related to carotene, xanthophyll, fucoxanthin, the anthocyanins, or the melanins. It is probably derived from the associated fats. The bearing of the adipochrome on the pathology of malignant disease is discussed.
S. S. Z.

Hydrolysis of Hexose-diphosphoric Acid by Various Organs. Y. TAKAHASHI (*Biochem. Z.*, 1924, **145**, 178—181).—Sodium hexose-diphosphate is hydrolysed *in vitro* by the kidneys, spleen, and muscle of the guinea pig, the activity of the organs diminishing in the order given (cf. also Tomita, A., 1922, i, 960).
J. P.

Determination, in Different Organs, of Polonium Injected into an Organism. (MME.) J. S. LATTÈS and A. LACASSAGNE (*Compt. rend.*, 1924, **178**, 771—773; cf. this vol., i, 461).—The distribution, in the rabbit, of polonium, after the injection of the latter, whether intravenously, subcutaneously, or intraperitoneally, is approximately the same. The spleen and kidney are richest in polonium, the former retaining it longer than the latter. The liver, lungs, and especially the heart, rapidly lose their initial polonium. When polonium is injected into a pregnant mouse, the placenta is the organ richest in polonium, which is absent from the amniotic fluid and the fœtus. E. E. T.

Bio-radioactivity. P. BECQUEREL (*Compt. rend.*, 1924, **178**, 795—797).—Nodon's observation of bio-radioactivity (this vol., i, 347; cf. Berthelot, *ibid.*, i, 348) was made by Tommasina in 1904. Radioactive potassium is present in all animal and vegetable protoplasm, and until an improvement in technique enables its detection, the question of bio-radioactivity must remain open.

E. E. T.

Liquid from *Tœnia echinococcus*. O. FLÖSSNER (*Z. Biol.*, 1924, **80**, 255—260).—The presence of considerable amounts of sodium and chlorine and of lesser amounts of potassium, calcium, ammonium, and magnesium in the liquid from *Tœnia echinococcus* was confirmed. Carbonic, sulphuric, and phosphoric acids were also present. The presence of glycogen, betaine, succinic acid, lactic acid, and purine bases was also established. The presence of betaine supports the theory of Kutscher and Ackermann that the metabolism of cold-blooded animals is similar to that of plants. The freedom of the liquid from albumin was confirmed. H. C. R.

Action of Rennet and of Heat on Milk. N. C. WRIGHT (*Biochem. J.*, 1924, **18**, 245—251).—The action of rennet and heat (up to 120° for ½ hour) on caseinogen does not alter the racemisation curves, which suggests that no cleavage takes place in the molecule by the above treatments. Any changes brought about must therefore be of a physical nature. The coloration of autoclaved milk is due to the caramelisation of the lactose, a reaction which appears to be catalysed by the presence of a colloid substrate of calcium caseinogate. The colour of caseinogen precipitated from autoclaved milk is due to adsorption of this pigment.

S. S. Z.

Cholesterol Content of Human Milk. F. W. FOX and J. A. GARDNER (*Biochem. J.*, 1924, **18**, 127—135).—The total cholesterol of 1—12 days' milk is higher than the average of the later period of lactation in the ratios of 1 : 0·59. S. S. Z.

Acidity of Urine Measured by Physico-chemical Methods. C. O. GUILLAUMIN (*Bull. Soc. Chim. biol.*, 1924, **6**, 14—25).—Emphasis is laid on the importance in urine analysis of the determination of [illegible] addition to the usual titration methods. If the [illegible] fractions of the acids present that are ionised [illegible]. It is suggested that the ratio, v/V = c.c. of

N/10-hydrochloric acid required to change p_H from 8·0 to 4·0÷c.c. required to change p_H from 8 to 2·7, might be used to indicate the average degree of dissociation of the organic acids present in urine, but in practice this does not appear to give a trustworthy result.

W. O. K.

Action of Sodium, Potassium, and Calcium Ions and of Uranyl Nitrate on the Spontaneous Rhythmic Movements of the Muscular Skin of the Earth-worm. P. C. HART (*Arch. Néerl. Physiol.*, 1924, 9, 1—29).—The rhythmic movements which preparations of the muscular skin of the earth-worm execute when suspended in Ringer's solution have been studied. The effects of variations in the composition of the solution are, in general, similar to those obtained with isolated organs of other animals. The potassium chloride in the perfusion fluid may be replaced by uranyl nitrate; normal movements are obtained when 10 mg. of uranyl nitrate replace 100 mg. of potassium chloride (cf. *Annual Reports*, 1919, **16**, 148).

E. S.

Action of some Physical and Chemical Agents on the Mobility of Ciliated Infusoria. E. and H. BIANCANI (*Compt. rend.*, 1924, **178**, 800—802).—Ciliated infusoria become permanently immobile under the influence of powerful ultra-violet radiation, a temporary immobility being produced by weak radiation. Salt solutions also induce immobility, isotonic solutions of different salts effecting the change at the same rate. Carbamide, ammonia, and iodine act similarly, the effect being proportional to the concentration. With all the agents mentioned, the dose–time curve is hyperbolic.

E. E. T.

Action of Iodoethylurethane and Iodoethyl Allophanate. B. VON ISSEKUTZ and A. TUKATS (*Biochem. Z.*, 1914, **145**, 1—9).—Ethylurethane, iodoethylurethane, and acetyliodoethylurethane ($CH_3{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}OC_2H_4I$) are increasingly toxic in the order given, whilst compared with the parent urethane, iodoethyl allophanate ($NH_2{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}OC_2H_4I$) shows a diminished toxicity. The latter is absorbed in the intestinal tract to a greater extent than the iodine derivatives of the fatty acids, and is excreted in the urine approximately as rapidly and completely as potassium iodide.

J. P.

Pharmacology of the Camphor Group. Comparison of an Isomeric Camphor with Japan Camphor. T. AMAKAWA (*Arch. Exp. Path. Pharm.*, 1924, **101**, 100—126).—The pharmacological action of 3-methyl-5-*iso*propyl-$\Delta^{2,3}$-*cyclo*hexenone (hexeton) is very similar qualitatively to that of camphor, but is several times stronger.

W. O. K.

Bactericidal Action of the Tellurium Derivatives of Aliphatic β-Diketones. II. G. T. MORGAN, E. A. COOPER, and A. W. BURTT (*Biochem. J.*, 1924, **18**, 190—201).—These compounds are extremely germicidal for various strains of bacteria, the bactericidal power being determined by the symmetry of the parent β-diketone and by the presence of methyl and ethyl groups in para-positions within the heterocyclic ring. Tellurium dipropionylmethane, fulfilling both these conditions of chemical structure, is therefore the most active of the series. The bactericidal power of these compounds increases considerably as the homologous series is ascended, until with the presence of an ethyl group and subsequent substitution of one methyl group, a limit is reached, and with further substitution of alkyl groups there is a diminution in efficacy. Position isomerism plays an important part in determining germicidal power. The tellurium compounds lose their strong bactericidal action in the presence of serum, but retain their inhibitory power. In urine, however, their germicidal power is retained. S. S. Z.

Comparative Germicidal Efficiency of Phenol, Mercuric Chloride, and Potassium Mercuri-iodide. J. C. CADORA [in part with R. W. LAMSON] (*J. Amer. Pharm. Assoc.*, 1923, **12**, 401—405).—The values without organic matter were 468·7 for mercuric chloride and 1100 for potassium mercuri-iodide. The minimum lethal dose for the three substances is 0·00035 g., 0·000012 g., and 0·000026 g., respectively. Compared with that of phenol as unity, the coagulating power of mercuric chloride is 55; no coagulating effect was observed with potassium mercuri-iodide. CHEMICAL ABSTRACTS.

Chemotherapeutic Researches in the Series 205 Baeyer. Carbamates of the Aminobenzoylaminonaphthalenesulphonic Acids. E. FOURNEAU, J. TRÉFOUËL, (MME.) J. TRÉFOUËL, and J. VALLÉE.—(See this vol., i, 382 and 504.)

Influence of certain Chemicals on the Rate of Reproduction of Yeast in Wort. N. A. CLARK (*J. Physical Chem.*, 1924, **28**, 221—231; cf. A., 1922, i, 501).—The rate of reproduction of yeast in wort at 25° follows a logarithmic law up to a certain limiting concentration, when the alcohol formed during fermentation begins to have an effect. The influence on this rate of phenol, methyl green, acetone, sodium bicarbonate, and hydrochloric and acetic acids has been studied. In general, the effect is to reduce the rate, which still, however, follows the logarithmic law. With increasing concentration of the poison there is also a resting period of increasing duration before reproduction begins. In every instance, a limiting concentration is reached above which no growth is observed, although it has been shown that this does not necessarily mean that the yeast is killed. When washed free from poison, it is still capable of reproduction. [Cf. *B.*, 1924, 395.] M. S. B.

Optimum Temperature of the Action of a Ferment or Lysin. I. BROWNLEE (*Biochem. J.*, 1924, **18**, 16—18).—The subject is treated mathematically. S. S. Z.

Nature, Constitution, and Mode of Action of Animal Tissue Enzymes. F. MAIGNON (*Compt. rend.*, 1924, **178**, 806—807; cf. this vol., i, 464).—Tissue and pancreatic enzymes, similar with regard to their content of metals, differ in their content of acids (silicic, phosphoric, and arsenic in the former case and hydrochloric in the latter). The tissue enzymes may be written in the form, $(SiO_4)^{II.H.H.II.}$, etc., those of the pancreatic juice as $Cl^{II.}$. The paper contains other (theoretical) matter. E. E. T.

Inactivation of Invertase by Heavy Metals. K. Myrbäck (*Ark. Kemi, Min., Geol.*, 1923, 8, No. 29, 1—37).—Experiments similar to those described by Euler and Svanberg (A., 1920, i, 689) have now been carried out with purer preparations of invertase. The extent to which the enzyme is inactivated by mercuric chloride varies greatly with the purity of the enzyme preparation, since the protein impurities are able to fix mercury and thus protect the enzyme; even with the most highly purified specimens of invertase, the first small additions of the mercury salt are without inactivating action. The purity of an invertase preparation is indicated by: (1) The absence, from the curve connecting relative activity with the proportion of mercuric chloride present, of the characteristic initial inflection that is shown when mercury-fixing impurities are present, (2) the constancy or gradual increase of the unimolecular reaction coefficient, and (3) the non-occurrence of auto-regeneration of the enzymic preparation.

Within the optimum zone, the inactivation by mercuric chloride is virtually independent of the hydrogen-ion concentration and, moreover, unlike what is the case with poisoning by silver, no acidity is capable of annulling the effect of the mercuric salt. Sucrose itself exerts a marked protective action. The mercury equivalent of invertase (per mol. of Hg) in the supposed compound Hg-invertase is calculated to be 3530, and the values $6{\cdot}6 \times 10^{-7}$ and $1{\cdot}0 \times 10^{-7}$ are found by two different methods for the dissociation constant of this compound.

With silver salts also, the amount needed to produce inactivation of invertase becomes very small when the enzyme is highly purified. Cysteine combines with very large proportions of silver, the acidity being without appreciable effect in this case. The poisoning action of copper or lead is similar to that of silver.

In view of the facts that the curve connecting the relative activity of the enzyme with the proportion of mercury present is a dissociation curve, that the acidity is without appreciable influence in the optimum zone, and that the poisoning is affected considerably by the concentration of the sucrose, it must be assumed that mercury forms with the enzyme a dissociating compound; in presence of sucrose, the invertase becomes distributed between the sugar and the mercury. With poisoning by silver, copper, or lead, other conditions must prevail, since the poisoning depends greatly on the acidity and is independent of the concentration of the substrate; in these cases, it is supposed that it is the enzyme-substrate compound which forms with the silver ion a very slightly dissociated salt.

Experiments on the influence of sodium acetate on the action of invertase yielded results similar to those obtained by Fales and Nelson (A., 1916, i, 174) with sodium chloride. T. H. P.

Inactivation of Invertase by Amines. K. Myrbäck (*Ark. Kemi, Min., Geol.*, 1923, 8, No. 32, 1—11).—The inactivation of invertase by *p*-toluidine as a function of the proportion of base present (cf. A., 1923, i, 496) is dependent only in slight degree on the hydrogen-ion concentration of the medium. Assuming that only the free enzyme, and not the enzyme-substrate compound, is able to fix the amine, values are derived for the dissociation constant of the enzyme-amine compound, which are virtually constant for different concentrations of the amine.

The degree of inactivation produced by aniline is not determined solely by the concentration of the base; the more acid solutions cause increased inactivation, which is due to an unknown factor. Ammonia inactivates invertase to as great an extent as do the aromatic amines. T. H. P.

Blood Enzymes. IV. Maltase of Dog's Serum: Influence on Activity of the Reaction of the Medium and of the State of Digestion. A. Compton (*Biochem. J.*, 1924, **18**, 173—177).—The maltase of the blood of the dog, like that of vegetable origin, requires an acid medium for its maximum activity (1·66 c.c. *N*/100 sulphuric acid to 55·5 c.c. of reaction mixture). The activity and the optimum temperature, *i.e.*, 55°, are the same whether the blood is collected during digestion or in the fasting state. S. S. Z.

Takalactase. C. Neuberg and O. Rosenthal (*Biochem. Z.*, 1924, **145**, 185—188).—Takadiastase preparations contain an enzyme—*takalactase*—which hydrolyses lactose practically completely in 216 hours. Lactose osazone is similarly resolved into galactose and glucosazone. In the presence of yeast and takalactase, lactose gives rise to carbon dioxide. J. P.

Fructosediphosphatase in Human Organs. I. E. Forrai (*Biochem. Z.*, 1924, **145**, 48—53).—Many dried human organs are capable of hydrolysing sodium fructosediphosphate, the percentage hydrolysis varying from 66% in the thyroids, to 19% in healthy muscle and 10% in blood-serum. A widespread distribution of fructosediphosphatase is inferred. J. P.

Differentiation of Human Phosphatases. E. Forrai (*Biochem. Z.*, 1924, **145**, 54—56).—From comparative studies of the capacities of extracts of various human organs to hydrolyse glycero-, saccharo-, and fructosedi-phosphoric acids, it is concluded that the phosphatases concerned are different and specific enzymes. J. P.

Determination of the Activity of a Laccase. P. Fleury (*Compt. rend.*, 1924, **178**, 814—816).—The activity of a laccase may be determined by aspirating air through the enzyme preparation in presence of guaiacol, the oxidation of which affords tetraguaiacoquinone. This substance is extracted with chloroform and determined colorimetrically. The lower the concentration of the laccase, the higher is its effectiveness, but, within certain limits, the ordinary linear relation holds between enzyme concentration and amount of substrate decomposed. Between these limits, the above method is accurate. E. E. T.

Mechanism of Oxidation in the Plant. II. Substances Capable of Behaving as Peroxydases. P. H. Gallagher (*Biochem. J.*, 1924, **18**, 29—38).—It is concluded that peroxydase activity is associated with aliphatic aldehydes, which do not act directly but after preliminary conversion by atmospheric oxygen into a substance of oxide nature. Peroxydase preparations prepared by alcoholic precipitation from the juices of vegetables such as the potato, the horse-radish, and the mangold contain a substance or substances of aldehydic nature. Oxides of some heavy metals induce oxidation of guaiaconic acid and of indophenol mixture by peroxide. The chemical nature of peroxydase action is discussed in the light of these results. S. S. Z.

Mechanism of Oxidation in the Plant. III. Peroxydase. Thermostability of the Peroxydase of the Mangold. P. H. Gallagher (*Biochem. J.*, 1924, **18**, 39—46).—Peroxydase of the mangold, inactivated by heat, becomes reactivated when the solution is allowed to remain some time in the cold. This reactivation has been studied quantitatively. The active and the inactivated solutions both contained iron and gave several reactions for aldehyde. Traces of iron added to aqueous solutions of aliphatic aldehydes give rise to an increase of peroxydase activity on standing in the cold. The zymogen of the peroxydase is probably an aldehyde which is activated by the catalytic action of iron after the inactivation by heat. S. S. Z.

Reaction of *Bacillus coli* applied to the Proteolytic Action of Serum (Abderhalden's "Ferments of Defence"). E. Wollman, V. Labernadie, (Mme.) E. Wollman, and (Mlle.) J. Ostrowski (*Ann. Inst. Pasteur*, 1924, **38**, 115—151).—The production of indole from albumin by *Bacillus coli* only occurs after previous proteolysis of the albumin (Wollman, *Compt. rend. Soc. Biol.*, 1919, **82**, 1263). It is thus an indicator of such proteolysis, and may be used instead of the methods of dialysis or optical rotation in carrying out Abderhalden's reaction. The application of this method gave no evidence for the existence of the "ferments of defence" postulated by Abderhalden. W. O. K.

Extraction of Sap from Living Tissues by means of Compressed Air. H. H. Dixon and N. G. Ball (*Sci. Proc. Royal Dubl. Soc.*, 1924, **17**, 263—266).—Liquid was forced out of the wood and leaves of branches by enclosing them in a strong cylinder, in such a way that their cut ends protruded, and increasing the pressure in the cylinder to about 20 atmospheres. This liquid was almost completely free from sugars, except when the leaves had been exposed to toluene vapour. The transport of carbohydrates from the leaves to the stem through the wood involves, in addition to a backward flow through the tracheæ, an increased permeability of the leaf cells. E. M. C.

Physiological Studies on Apples in Storage. J. R. Magness and H. C. Diehl (*J. Agric. Res.*, 1924, **27**, 1—38).—The changes in apples after picking are, in the main, a continuation of those occurring during ripening on the tree. The softening of stored apples is accelerated by increased temperature. The decrease in acidity during storage was practically the same for all varieties of apples, and was independent of the original acidity. Coating the surface of apples with oil or similar material, by reducing the gaseous exchange, retards ripening. So long as anaërobic respiration does not occur, the flavour of the fruit is not detrimentally affected. The higher the temperature of storage, the smaller is the thickness of the coating which will bring about anaërobic respiration and bad flavour. The retardation of ripening appears to be due both to the reduced amount of oxygen and the increased amount of carbon dioxide in the intracellular spaces. Storage of apples in an atmosphere containing up to 10% of carbon dioxide delayed softening, with no apparent loss of quality, but greater proportions caused a bad flavour. A. G. P.

Essential Oil of Manuka (*Leptospermum Scoparium*). R. GARDNER (*J. Soc. Chem. Ind.*, 1924, **43**, 34—35T).—The leaves of the New Zealand wild shrub known as "manuka" yield about 0·45% of greenish-yellow essential oil, d^{15} 0·921, n_D 1·50, b. p. 160—270°/760 mm. The oil consists approximately of phenols (leptospermol), 2·8%; terpenes, 2·8%; cinnamic esters (calculated as ethyl cinnamate), 4·8%; other esters (calculated as $CH_3{\cdot}CO_2{\cdot}C_{10}H_{15}$), 12·9%; semi-solid, non-volatile substances, 7·7%; sesquiterpene, 69·0%. W. P. S.

Protein and Vitamin-*A* Content of the English Walnut. H. L. MIGNON (*Amer. J. Physiol.*, 1923, **66**, 215).—Tannins present in the skins of English walnuts interfere with the extraction of the walnut globulin and constitute a growth-limiting factor in the diets of rats and mice. Vitamin-*A* is present in extremely small amounts. The distribution of nitrogen as amino-acids in walnut globulin, as determined by Van Slyke's method, is: cystine, 0·86; amide, 9·99; humin, 1·84; arginine, 39·13; histidine, 5·74; lysine, 10·61; monoamino-, 30·26; non-amino-, 0·88%.

CHEMICAL ABSTRACTS.

Relation between the Chemical Structure of Bile Acids and their Phytopharmacological and Zoöpharmacological Reactions. D. I. MACHT and O. R. HYNDMAN (*J. Pharm. Exp. Ther.*, 1924, **22**, 483—490).—The inhibition of the growth of seedlings by taurocholic and glycocholic acids appears to be due to the cholic acid in the molecules, since glycine and taurine have little or no action on the growth of seedlings (*Lupinus albus* or *Vicia faba*) or on the reactions of rats in a circular maze, whilst cholic (and also choloidinic) acid is very active. W. O. K.

Saponin of *Panax repens*, Maxim. I. Y. MURAYAMA and T. ITAGAKI (*J. Pharm. Soc. Japan*, 1923, No. 501, 783—789; cf. Inoue, *ibid.*, 1902, No. 242, 356).—After treatment with ether, crushed *Panax repens*, Maxim, was extracted with hot alcohol; from the extract a saponin (5%) was isolated as a white, amorphous powder (m. p. 180—190°), which has a bitter taste.

When shaken with water, it dissolves slightly with foaming; it gives a clear solution on the addition of sodium carbonate. It behaves as an acid, thus supporting the hypothesis of Asahina and Momotani (*ibid.*, 1914, No. 384, 117). It contains 0·33% of ash. When hydrolysed with 3% hydrochloric acid it gave dextrose and a sapogenin (15%). The latter was obtained as white, lustrous needles (m. p. 303—304°). The sapogenin gives the same colour reactions as the saponin, but has no taste. It gives two diacetyl derivatives: one, plates (m. p. 207—210°), and the other, needles (m. p. 257—260°). K. K.

Isolation and Identification of Rutin from the Flowers of Elder (*Sambucus Canadensis*, L.). C. E. Sando and J. U. Lloyd (*J. Biol. Chem.*, 1924, **58**, 737—745).—The yellow pigment "eldrin" from the flowers of the elder (Lloyd, *Eclectic Med. J.*, 1920, **80**, 591) is shown to be identical with rutin from *Eschscholtzia* (Sando and Bartlett, A., 1920, i, 446) in its appearance, composition, products of acid hydrolysis (quercetin, dextrose, and rhamnose), and in its absorption spectrum. The yield of quercetin on hydrolysis is slightly higher than that calculated, owing to the presence of an impurity. G. M. B.

Proteins of Oats. H. Lüers and M. Siegert (*Biochem. Z.*, 1924, **144**, 467—476).—Various protein fractions prepared from oats by Osborne's methods, and belonging to the alcohol-, salt-, and alkali-soluble groups, were examined for their products of hydrolysis. The results are given in tabular form. The differences between the alcohol-soluble proteins of oats and those of the other cereals lie chiefly in the higher cystine and in the medium histidine content. The globulins of oats contain less arginine and decidedly more non-amino nitrogen than the globulins of other cereals. Avenaline, the protein characteristic of oats, is rich in arginine and histidine. Although there are many points of similarity between the nitrogen distribution of the proteins of oats and of other cereals, there is not a complete agreement. The proteins of oats are therefore to be regarded as a distinct group. S. S. Z.

Influence of Phylogeny on the Constitution of the Alkaloids. J. Gadamer (*Pharm. Monatsh.*, 1923, **4**, 157—160; from *Chem. Zentr.*, 1924, i, 56).—Certain families of plants yield characteristic alkaloids. From this fact it is possible to draw conclusions as to the constitution of alkaloids from different species of the same family. G. W. R.

Basic Substances from the Juice of the Alfalfa Plant [Lucerne]. C. S. Leavenworth, A. J. Wakeman, and T. B. Osborne (*J. Biol. Chem.*, 1923, **58**, 209—214).—The filtrate obtained from the press-juice after precipitation by addition of 53% by weight of alcohol (A., 1922, i, 1104) has been hydrolysed by boiling for 12 hours with 25% sulphuric acid and the product examined for basic substances according to Kossel's method. The following substances were isolated: arginine, stachydrin (cf. Steenbock, A., 1917, i, 439), lysine, and a *compound* which was apparently a purine derivative. The latter was obtained from the mercuric sulphate fraction and gave a *picrate*, silky needles, m. p. 298°, and a *hydrochloride* (?), long plates, m. p. about 252°, which contained 31·8% of nitrogen. It is not known whether these bases are present in the press-juice in the free state or whether they are liberated during hydrolysis. Van Slyke's method for analysing the hydrolytic products of proteins is not applicable to the water-soluble constituents of forage plants. E. S.

Extraction of Nitrogenous Constituents from Plant Cells. W. E. TOTTINGHAM, E. R. SCHULZ, and S. LEPKOVSKY (*J. Amer. Chem. Soc.*, 1924, **46**, 203—208).—The investigation deals with the efficiency of various methods of desiccation and extraction as related to the proportions of total soluble nitrogenous compounds and soluble proteins in leaves of the barberry and sugar beet. The influence of freezing and drying on the distribution of nitrogen in plant cells is discussed. The results obtained indicate the desirability of extracting with water as general usage in fractionating the nitrogenous constituents of plant cells; water extracts the greater part of the proteins exposed by crushing the cells of fresh tissue. Chibnall's method of extraction does not sharply separate non-protein from protein nitrogen. F. A. M.

Presence of Vernine (Guanosine) in the Green Leaves and Berries of the Coffee Tree (*Coffea Arabica*, L.) and its Relation to the Origin of Caffeine in this Plant. T. DE A. CAMARGO (*J. Biol. Chem.*, 1924, **58**, 831—834).—A pentoside containing guanine, found in the green leaves and berries of this species, is probably the guanosine previously found in several plants (Schultze, A., 1886, 157, 736) and in nucleic acid (Levene and Jacobs, A., 1909, i, 620). This substance is probably the origin of caffeine in the leaves and berries of the coffee tree. It is transformed by enzymes to guanine, then to xanthine, and finally to caffeine. G. M. B.

Method for Sterile Cultures of the Higher Plants. E. BOBKO (*Z. Pflanz. Düng.*, 1924, **A**, **3**, 41—44).—The apparatus consists of a wide-necked vessel, to hold the nutrient solution, inside the wide neck of which is a piece of net stretched on a frame. The whole is covered with a dome-shaped cap, having cottonwool-plugged tubulures through which seed and sand may be introduced. The lower vessel has a side tube through which an air current or renewed nutrient solution may be passed. The vessel and solution are first sterilised; the seeds are separately sterilised and then introduced on to the gauze and covered with sterile sand. The cover is then removed. A. G. P.

Comparison of the Soil Solution by the Displacement Method and the Water Extract of Alkali Soils. P. L. HIBBARD (*Soil Sci.*, 1923, **16**, 465—471).—When the composition of 1 : 5 water extracts of nine alkali soils was used as a basis for the calculation of the composition of the soil solution, results were obtained which were at variance with those given by an analysis of the solution obtained from the same soil by the displacement method (A., 1921, i, 214). Only in the case of chlorides, nitrates, and sodium were the results given by the two methods in approximate agreement. Calcium and magnesium may be either under- or over-estimated by the water extract method. All the other ions were over-estimated to varying degrees. Analysis of 1 : 5 water extracts of soils is thus liable to give a distorted and, usually, an unfavourable impression as to the composition of the soil solution and the suitability of the soil for plant growth. H. J. P.

Replacement of Soil Potassium. S. C. VANDECAVEYE (*Soil Sci.*, 1924, **17**, 91—96).—Organic manures (clover hay and dung) increased the amount of replaceable potassium in soil (as determined by neutral salt extraction) proportionally to the amounts added. Evidence is given that this liberation of replaceable potassium is largely a chemical phenomenon, and is not the result of biological activities or the production of carbon dioxide in the soil. A. G. P.

Reciprocal Repression Exerted by Calcic and Magnesic Additions upon the Solubility of Native Materials in Surface Soil. W. H. MACINTIRE, W. M. SHAW, and J. B. YOUNG (*Soil Sci.*, 1923, **16**, 449—464).—Lysimeter experiments are recorded in which magnesium and calcium compounds were added to the soil in varying quantities and with the supplementary use of sulphur compounds. In all cases, the addition of lime increased the calcium content of the drainage water and depressed that of magnesium. The reverse occurred when magnesia was substituted for lime. Ferrous sulphate, pyrites, and sulphur each increased the drainage losses of calcium and magnesium; but if used in conjunction with lime, the calcium losses were further increased and those of magnesium lessened. Similarly, magnesia, coupled with either of the sulphur compounds, brought about increased leaching of magnesium, and a depression of the loss of calcium normally occasioned by the sulphur compounds alone. Lime and magnesia in soil slowly revert to an insoluble and unavailable condition. Excessive liming may so depress the solubility of magnesium salts, as to cause a chlorotic condition in plants due to deficiency of magnesium. A. G. P.

Effect of Soil Suspensions on the Solubility of the Sulphate Radical in the System $Ca(OH)_2$–$CaSO_4$–H_2O. W. H. MACINTIRE and W. M. SHAW (*Soil Sci.*, 1924, **17**, 65—89).—In small amounts lime increased the amount of dissolved sulphate in a ferrous sulphate–soil–water suspension. Larger amounts of lime, however, almost eliminated dissolved sulphates from the suspensions, even when a period was allowed, before adding lime, for the reaction between soil and ferrous sulphate to proceed. If the excess of lime were removed from the soil suspension by the addition of sodium carbonate or by carbon dioxide the depressive effect on the solubility of sulphates disappeared. Here also the same effects were observed when the addition of sodium carbonate was delayed. The addition of soil to solutions of calcium sulphate caused the removal of considerable amounts of sulphate from solution. Similar experiments are recorded in which calcium carbonate, magnesium oxide, and carbonate were used in conjunction with ferrous sulphate (cf. *Soil Sci.*, 1923, **16**, 159). Soil structure played an important part in sulphate adsorption. Ignited soil contained more soluble sulphate than the fresh sample, but also adsorbed more sulphate from added solutions, and the effects of lime were accentuated. Greater quantities of sulphate were removed by extracting soil with large amounts of water than by rainwater leaching in lysimeters. A. G. P.

Factors affecting the Growth of Crops on Acid Soils. S. D. CONNER (*Ind. Eng. Chem.*, 1924, **16**, 173—175).—The capacity of a soil to neutralise calcium hydroxide, carbonate, or acetate is a measure of the total acidity, both organic and inorganic. Methods depending on the action of a salt of a strong acid and a strong base, such as potassium nitrate, give a measure of the inorganic acid silicates, but not to any great extent of the organic acids. The expression (inorganic acidity)^2/(organic acidity) gives a better indication of the lime needs of both organic and inorganic soils than that given by any single method of determining acidity. The toxicity of soil acidity may be due to both aluminium ions and hydrogen ions. Some crops, such as maize and radishes, are more sensitive to aluminium ions than to hydrogen ions, whilst others, such as red clover and beets, are more sensitive to hydrogen ions than to aluminium ions. Both phosphates and lime are needed to correct the toxicity of aluminium and hydrogen ions in most acid soils. H. C. R.

Behaviour of Lime in the Soil. O. LEMMERMANN and L. FRESENIUS (*Z. Pflanz. Düng.*, 1924, A, 3, 1—20).—The relationship between the action of various calcium compounds on soils was determined by shaking together soil and various salt solutions. Calcium, supplied to soil as chloride or bicarbonate, was "fixed" largely by base exchange in accordance with the usually accepted views. If slaked lime was used, the calcium was held by adsorption. Carbon dioxide can partly, but not wholly, remove calcium from this adsorbed condition. The addition of calcium hydroxide to soils accelerated the decomposition of organic matter. This occurred even when the amount of calcium hydroxide added was so adjusted that the whole of it would be adsorbed by the soil colloids. The addition of small amounts of lime to soil suspensions caused increased dispersion of the clay, larger amounts producing the normal flocculation. The permeability to water of soil to which successively increasing amounts of lime were added decreased with the smaller additions, and increased as the proportion of lime was further increased. A. G. P.

Determination of Acidity of Soils. R. M. BARNETTE and others.—(See this vol., ii, 347.)

Organic Chemistry.

Primary Products of the Combustion of Carbon. K. Kullgren (*Gas- u. Wasserfach*, 1924, **67**, 226—229).—Carbon dioxide was the main product formed when air, freed from carbon dioxide, was passed over heated retort coke, at 260—410°, but 20% of its weight of carbon monoxide was always present. Dry air reduced the velocity, but did not affect the course of the oxidation. [Cf. *B.*, 1924, 457.] T. S. W.

Sulphochromic Oxidation of Organic Substances and Coals in Presence of Catalysts. D. Florentin (*Bull. Soc. chim.*, 1924, [iv], **35**, 228—230).—The oxidation of the carbon in organic compounds and coals to carbon dioxide by means of the sulphochromic mixture is complete in the presence of a small quantity of a mercury salt. With other catalysts (copper sulphate, silver chromate), or with no catalyst, a certain amount of carbon monoxide is produced also. E. E. T.

Preparation of *n*-Hexane. M. Faillebin (*Bull. Soc. chim.*, 1924, [iv], **35**, 160—161).—Pure *n*-hexane is prepared by the action of pulverised sodium on dry *n*-propyl bromide (Würtz reaction). The sodium is freed from sodium hydroxide by fusion under xylene and is then pulverised under the same liquid. E. E. T.

Conversion of [Solid] Paraffin by Heating under Pressure in the Presence of Hydrogen, Methane, and other Gases. H. I. Waterman and J. N. J. Perquin (*Proc. K. Akad. Wetensch.*, 1924, **27**, 132—139).—The results of further experiments are given. [Cf. *B.*, 1924, 500.] T. H. P.

Constitution of Melene. J. Marcusson and F. Böttger (*Ber.*, 1924, **57**, [*B*], 633—635).—Melene, found by Pictet and Bouvier (A., 1915, i, 513) in coal, in vacuum-tar, in Galician paraffin, and in the products of distillation of beeswax, was assumed to be a solid naphthene, $C_{30}H_{60}$. The authors have now found that Indian paraffin, m. p. 59—60°, consists very largely of melene, which can be readily isolated by crystallisation from benzene and then from light petroleum. It has m. p. 62—63°, d^{65} 0·7913; d^{25} 0·9037; n^{90} 1·4228. Analyses indicate the composition $C_{30}H_{62}$; oxidation with strong hot nitric acid gave a mixture of aliphatic acids, whereas naphthenes under similar conditions gave nitro compounds. Similar differences in behaviour were found on oxidising catalytically with air in presence of manganese dioxide, melene yielding solid fatty acids, whilst naphthenes yielded polynaphthenic acids. Lastly, melene is slowly assimilated at 30° by *Bacterium aliphaticum*, which is incapable of attacking naphthenes. Melene is therefore a paraffin and not a naphthene. F. A. M.

Constitution of Kerogen. J. W. McKinney (*J. Amer. Chem. Soc.*, 1924, **46**, 968—979).—A shale from Albert Mines, New Brunswick, on extraction with acetone yielded 1·36% (calc. on the shale), which is about 4% of the kerogen. The hydrocarbons, amounting to 85% of the extract, on repeated fractionation in a vacuum yielded 15 separate fractions. These, by cooling, were split up into 28 different hydrocarbons consisting of the homologues: $C_{14}H_{30}$ to $C_{26}H_{54}$, $C_{12}H_{24}$ to $C_{24}H_{48}$, $C_{25}H_{48}$, d^{25} 0·8877, $C_{26}H_{50}$, d^{25} 0·8964. Of these, the two last do not appear to have been previously obtained. A. C.

Silver as Catalyst for the Absorption of Ethylene by Sulphuric Acid. W. Lommel and R. Engelhardt (*Ber.*, 1924, 57, [*B*], 848).—The catalytic acceleration of the absorption of ethylene by sulphuric acid by means of silver salts (cf. Gluud and Schneider, this vol., i, 359) has been observed previously (cf. D.R.-P. 393632). The change consists in the successive addition of ethylene to the silver salt and production of ethyl hydrogen sulphate. Addition occurs very rapidly at the atmospheric temperature, whereas the second reaction does not take place with sufficient rapidity below 40°. The absorption of ethylene by aqueous solutions of silver nitrate (10%) and phosphoric acid (4%) may be used for the gas-analytical determination of ethylene; the gas can be removed subsequently by evacuating the solutions with a water-pump. H. W.

Formation of Metallic Acetylides. J. F. Durand (*Bull. Soc. chim.*, 1924, [iv], 35, 161—171).—Acetylene is a very feeble acid (cf. A., 1902, i, 525) and the general methods of preparing salts are now applied to the formation of acetylides. By the action of pure acetylene on solutions of cupric hydroxide in concentrated potassium but not in sodium hydroxide, at 35° a reddish-brown precipitate, CuC_2, was obtained (cf. A., 1897, i, 309) which, immediately after preparation, yielded acetylene with hydrochloric acid or potassium cyanide, but after standing it polymerised and then gave with these reagents an organic, colloidal substance free from copper. Acetylene did not react with copper hydride, but with boiling solutions of zinc ethyl in light petroleum the white zinc acetylide, ZnC_2, was precipitated (A., 1923, i, 449), which gave pure acetylene with water and sodium hydroxide solution; it decomposed (without explosion) at 350° (cf. magnesium and alkaline-earth acetylides).

Solutions of acetylene in acetone gave with mercury ethyl a white, crystalline substance, the precipitation of which was reversible. Boiling solutions of mercury ethyl in light petroleum gave with acetylene gas mercury and carbon, the temperature being too high for carbide formation; boiling solutions of mercury and of lead phenyls in the same solvent gave no result, neither did a benzene solution of lead ethyl. Attempts to prepare aluminium acetylide, $Al_2(C_2)_3$, by the action of acetylene on aluminium carbide at 400—500° failed. E. E. T.

Preparation of Alkyl Chlorides. J. F. Norris and H. B. Taylor (*J. Amer. Chem. Soc.*, 1924, 46, 753—757; cf. A., 1916, i, 461; 1920, i, 831).—Alcohols are converted into the corresponding chlorides when heated for 1 hour under a reflux condenser with concentrated hydrochloric acid and zinc chloride. The lower alkyl halides may be purified from higher polymerides by heating gently under a reflux condenser with concentrated sulphuric acid. The best results are obtained when the molecular ratio of alcohol, hydrogen chloride (as concentrated hydrochloric acid), and zinc chloride is 1 : 2 : 2; yields varying from 60—82% were obtained. Alkyl chlorides were produced from the following alcohols: methyl, ethyl, *n*- and *iso*-propyl, *n*- and *sec*.-butyl, *iso*-amyl, pentan-β-ol, cetyl, β-phenylethyl, γ-phenylpropyl, *m*-nitrobenzyl, and *p*-nitrobenzyl. C. J. S.

Preparation of Various Aliphatic Halides and Halohydrin Compounds. M. T. Bogert and E. M. Slocum (*J. Amer. Chem. Soc.*, 1924, **46**, 763—768).—The method described by Adams and Vorhees (A., 1919, i, 306) for the preparation of alkyl iodides by the use of phosphorus and iodine has been modified so as to avoid the employment of special apparatus. Iodides have been obtained from *n*- and *iso*-propyl, *n*- and *iso*-butyl, and *iso*amyl alcohols (molecular ratio of alcohol, phosphorus, and iodine, 3 : 1 : 3). The trihalides of phosphorus may be used instead of the pentahalides for the conversion of propylene glycol into trimethylene bromide or iodide. Trimethylene bromohydrin and iodohydrin were prepared by passing the dry halogen hydride into propylene glycol; by conducting the operation in the presence of anhydrous benzene, a yield of 90% of the bromohydrin was obtained. A 50% yield of propylene glycol monoacetate was obtained by the action of acetyl chloride on propylene glycol. β-Chloroethyl acetate was obtained in very good yield by the action of a large excess of acetyl chloride on ethylene chlorohydrin. This method was applied to the production of *γ-bromopropyl acetate*, b. p. 88—90°/22 mm., when a yield of 90% was obtained. The best method for the preparation of γ-chloropropyl acetate consists in heating a mixture of propylene glycol, acetyl chloride, and zinc chloride in a sealed vessel for 8 hours at 100°. β-Iodoethyl acetate was obtained in 70% yield from the corresponding chloro compound by the action of excess of potassium iodide in methyl-alcoholic solution; γ-iodopropyl acetate was prepared in 88% yield by passing dry hydrogen iodide into an equimolecular mixture of propylene glycol and glacial acetic acid cooled to 0°. The *methylene ether* of *trimethyl iodohydrin*, $CH_2[O(CH_2)_3I]_2$, b. p. 180—193°/12 mm., was obtained (yield 60%) when a mixture of equimolecular proportions of trimethylene iodohydrin and trioxymethylene was saturated with dry hydrogen chloride, a second molecular proportion of the iodohydrin added, and the reaction completed by warming; it yields formaldehyde and iodopropyl alcohol when boiled with 20% sulphuric acid. C. J. S.

Action of Hydrogen Chloride on Methyl Alcohol. S. R. Carter and J. A. V. Butler (*J. Chem. Soc.*, 1924, **125**, 963).—A solution of hydrogen chloride (400 g.) in methyl alcohol (1 litre) on standing at 18° for 4 days becomes saturated with methyl chloride which is then steadily evolved. The activity of methyl alcohol is thus far greater than that of higher alcohols. F. G. M.

Toxic Properties of Methyl Alcohol. S. Bodforss (*Svensk Kem. Tidskr.*, 1923, **35**, 333—335; from *Chem. Zentr.*, 1924, i, 574—575).—Methyl alcohol is toxic even when pure, and may exert a toxic effect when applied externally. G. W. R.

Determination of Methyl Alcohol. W. M. Fischer and A. Schmidt.—(See ii, 427.)

Detection of Methyl Alcohol. A. Kling and A. Lassieur.—(See ii, 428.)

Unsaponifiable Constituents (Higher Alcohols) of Shark and Ray Liver Oils. III. Y. Toyama (*Chem. Umschau*, 1924, **31**, 61—67; cf. A., 1923, i, 979).—Batyl and selachyl alcohols were prepared from the livers of *Chimæra barbouri* (Garman) and *Narcacion tokionis* (Tanaka). The analyses given by these preparations agreed better with formulæ containing 21 carbon atoms than with the formulæ containing 20 carbon atoms previously assigned to these alcohols. The solid portion of the unsaponifiable matter of these oils contains another alcohol homologous with batyl alcohol which is named *chimyl alcohol* and probably has the formula $C_{19}H_{40}O_3$. This alcohol occurs in the liver oils of several sharks and *Chimæra* and also in many cases is present in greater quantity than batyl alcohol. No trace of the unsaturated alcohol corresponding to chimyl alcohol could be found in these oils. Selachyl acetate had b. p. 242—244°/5 mm., n_D^{20} 1·4550, d_4^{20} 0·9417, iodine value (Wijs) 64·5, saponification value 260·0, molecular refraction 122·8 (calc. 122·0). Selachyl alcohol prepared from the acetate had b. p. 236—239°/5 mm., n_D^{20} 1·4691, d_4^{20} 0·9180, iodine value (Wijs) 79·5, molecular refraction 103·9 (calc. 103·3). The transformation of selachyl alcohol into batyl alcohol on hydrogenation was confirmed. By oxidising selachyl acetate with potassium permanganate in acetic acid solution nonoic acid and an acid of the formula $C_{11}H_{21}O(OAc)_2{\cdot}CO_2H$ were obtained. The formula

$$CH_3{\cdot}[CH_2]_7{\cdot}CH{:}CH{\cdot}C_{11}H_{21}O(OH)_2$$

is therefore indicated as representing selachyl alcohol. The principal product obtained on the dry distillation of selachyl acetate is either oleyl alcohol or nonodecyl alcohol. H. C. R.

Methyl Ethyl Sulphate as an Alkylating Agent. T. K. Thayer (*J. Amer. Chem. Soc.*, 1924, **46**, 1044—1046).—*Methyl ethyl sulphate*, b. p. 198—200°/742 mm., is prepared by adding ethyl chlorosulphonate (1·3 equivalents) to a suspension of sodium methoxide in dry ether. The yield was 19·7% of the theoretical. The alkylating powers of methyl sulphate and methyl ethyl sulphate were compared by alkylating solutions of phenol. Using methyl sulphate, the yield of anisole was 74·2% of the theoretical. With methyl ethyl sulphate, 56·7% of the phenol was converted into anisole and 13·4% into phenetole, which shows that the methyl group has the greater alkylating power. A. C.

Laboratory Preparation of Ethyl Sulphate. E. V. LYNN and H. A. SHOEMAKER (*J. Amer. Chem. Soc.*, 1924, **46**, 999—1001).—A mixture of alcohol (50 g.) and concentrated sulphuric acid (104·5 g.) is allowed to drop on to anhydrous sodium sulphate (90 g.) in a flask fitted with a condenser and arranged for vacuum distillation. The flask is kept at 155—165° (optimum temp.) by an oil-bath and the pressure maintained at 20—45 mm. The mixture enters through a capillary tube at about 120—150 drops per minute. The time of distillation for the above quantities is 1 to 1½ hours. The ethyl sulphate is separated from the alcohol in the distillate, washed with dilute sodium carbonate and then with cold water, and dried over anhydrous sodium sulphate. The product (32·6 g.) is almost pure and is neutral to litmus. A. C.

Action of Mixed Dialkyl Sulphates on Mixed Organo-magnesium Compounds. L. BERT (*Compt. rend.*, 1924, **178**, 1182—1184).—Methyl, propyl, *iso*propyl, *n*-butyl, and *iso*amyl ethyl sulphates were prepared by the action of ethyl chlorosulphonate on the corresponding sodium alkoxide. Bushong's observations (A., 1903, i, 732) on the *iso*propyl and *iso*amyl compounds were confirmed and the following constants are given for the methyl compound: b. p. 85°/15 mm., $d^{16\cdot5}$ 1·228, $n_D^{16\cdot5}$ 1·399. *Ethyl propyl sulphate* is a colourless oil, b. p. 107—108°/18 mm., $d^{16\cdot5}$ 1·140, $n_D^{16\cdot5}$ 1·411; *ethyl* n-*butyl sulphate*, a colourless oil, b. p. 117—118°/20 mm., d^{18} 1·112, n_D^{18} 1·415. Magnesium phenyl bromide reacts with all the above substances, yielding toluene in the case of methyl ethyl sulphate and ethylbenzene with the other four. H. J. E.

Explosive Decomposition of Glyceryl Trinitrate. AUDIBERT (*Compt. rend.*, 1924, **178**, 1167—1169).—The decomposition of glyceryl trinitrate on explosion takes place in two stages; the first (explosive reaction) is represented by the equation $C_3H_5O_9N_3 \longrightarrow 2CO+CO_2+2\cdot5H_2+1\cdot5N_2O+1\cdot75O_2+21$ cal., whilst the second (residual reaction) gives rise to the final system, $3CO_2+2\cdot5H_2O+1\cdot5N_2+0\cdot25O_2$, with a further evolution of 319 cal. Neither reaction is instantaneous; completion of the second depends on the conditions of reaction. H. J. E.

Action of some Halohydrins on Normal Sodium Phosphate in Aqueous Solution and on some Glycerophosphates. O. BAILLY and J. GAUMÉ (*Compt. rend.*, 1924, **178**, 1191—1193).—Similar results to those obtained with the chlorohydrin of glycerol and normal sodium phosphate (Bailly, A., 1916, i, 113) were observed in the cases of the bromohydrin and the iodohydrin, but the two stages of the reaction were more clearly differentiated. The authors have prepared the *normal glycerophosphates* of *sodium, potassium*, and *strontium* and the *acid glycerophosphates* of *barium, strontium*, and *calcium*. H. J. E.

Ease of Oxidation of Organic Substances at the Ordinary Temperature. M. GOMPEL, A. MAYER, and R. WURMSER (*Compt. rend.*, 1924, **178**, 1025—1027).—Solutions of formic, acetic, propionic, oxalic, succinic, citric, lactic, and pyruvic acids, glycine, alanine, and dextrose when shaken with blood charcoal at 40° evolve carbon dioxide. The rate of evolution of the gas is considerably affected by the presence and concentration of hydrogen ions, especially in the case of the acids of greater dissociation constant. The authors point out the biological significance of their observations. H. J. E.

Mechanism of Oxidation Processes. VII. H. Wieland (*Annalen,* 1924, **436**, 229—262).—I. [With A. Wingler.]—**Catalytic Fission and Oxidation of Keto-acids.**—Under the influence of palladium black, vegetable charcoal, and animal tissue, dilute aqueous solutions of keto-acids are hydrolysed with loss of carbon dioxide (cf. A., 1915, i, 354, 1046; 1916, i, 772). In this way, oxalacetic acid yields pyruvic acid, pyruvic acid gives acetic acid, malic acid yields acetic acid, and α-keto-β-phenylpropionic acid gives phenylacetic acid, benzaldehyde, benzoic acid, and oxalic acid. The reaction takes place in an atmosphere of nitrogen, provided that a hydrogen acceptor such as methylene-blue or *p*-benzoquinone is present. Traces of acetaldehyde were detected in experiments with pyruvic acid and washed animal tissue. The mechanism of the action is discussed.

II. [With H. Lörenskiold.]—**Mode of Reaction of Hydrogen Peroxide. Critical Experiments on Thunberg's Theory of Carbon Dioxide Assimilation** (cf. A., 1923, i, 1271).—On distilling hydrogen peroxide with pure lead carbonate the authors could detect no formaldehyde in the distillate, and Thunberg's results are considered to be due to the presence of traces of acetate in his lead carbonate. Only the slightest traces of formaldehyde were formed when formic acid was distilled with hydrogen peroxide, and the observation of Wislicenus (A., 1918, i, 472) that formic acid is formed in the oxidation of bicarbonates with hydrogen peroxide has been verified under conditions precluding the possibility of formic acid being introduced from atmospheric sources.

The results obtained by Dakin (A., 1908, i, 74) and Neuberg (A., 1915, i, 214, 215) in the oxidation of organic acids with hydrogen peroxide have been confirmed, but it is shown that the presence of ferrous iron is not essential. Comparative experiments with acetic acid and glycollic acid showed that formaldehyde was formed very much more rapidly in the latter case, and the view is expressed (cf. A., 1901, i, 310) that glycollic acid is the first stage in the oxidation of acetic acid with hydrogen peroxide. [Cf. i, 612.]

Glyoxylic acid, on oxidation with the same reagent, yields carbon dioxide and formic acid (cf. A., 1904, i, 474). In the case of butyric, crotonic, and β-hydroxybutyric acids, in addition to the aldehyde, considerable quantities of acetone are formed. Cinnamic acid yields chiefly the aldehyde; the saturated acid yields the aldehyde and ketone in approximately equal amounts. Malic acid, like succinic acid, is oxidised to acetic acid.

III. [With H. Rau.]—**Decomposition of Dihydroxyethyl Peroxide with Alkali** (cf. A., 1923, i, 650).—The decomposition of dihydroxyethyl peroxide with sodium hydroxide in the presence of silver below 0° follows the course: OH·CHMe·O·O·CHMe·OH $\longrightarrow$ $2Me·CO_2H+H_2$, to the extent of 40%, whereas at 15° only 30% of the peroxide decomposes in this way. The alternative decomposition: OH·CHMe·O·O·CHMe·OH $\longrightarrow$ $Me·CO_2Na+CHO·Me+2H_2O$, has therefore the greater temperature coefficient. [Cf. also A., 1920, i, 709.] R. B.

Purification of Acetic Acid. K. J. P. Orton and A. E. Bradfield (*J. Chem. Soc.*, 1924, **125**, 960—961).—Acetic acid is best purified by distillation with chromium trioxide (2 g. per 100 c.c. of acid); the first 5% is rejected. The main fraction (85—90%), if distilled through an 8-pear still-head, melts at 16·2—16·4°, and is free from impurities which react with bromine. F. G. M.

Identity of Phocenic and Valeric Acids. E. André (*Compt. rend.*, 1924, **178**, 1188—1191).—Synthetic and natural valeric acids were found to have boiling points almost identical with those of specimens of phocenic acid obtained from dolphin-head oil and from porpoise fat. Amides of all four specimens exhibited almost identical melting points, which were unchanged on mixing the substances in pairs. The statement that phocenic acid is a mixture of butyric and caproic acids (Lewkowitsch, "Chemical Technology and Analysis of Oils, Fats, and Waxes," 5th ed., i, 152) is thus regarded as incorrect. H. J. E.

αβ-Dihalogenated Amylacrylic Acids. C. Moureu and M. H. Schindler (*Bull. Soc. chim.*, 1924, [iv], **35**, 171—178).—*αβ-Dibromoamylacrylic acid* [*αβ-dibromo-Δ^α-octenoic acid*], a colourless liquid which will not crystallise, b. p. 144° (3 mm.), d_4^{18} 1·6444, $n_D^{19·5}$ 1·5320, is prepared by direct addition of bromine in chloroform solution to amylpropiolic acid. The *potassium, silver,* and two unstable *lead* salts, $(C_5H_{11}·CBr{:}CBrCO_2)_2Pb$ and

$$(C_5H_{11}·CBr{:}CBrCO_2)_2Pb·PbO,$$

are described. *αβ-Di-iodo-Δ^α-octenoic acid*, white needles, m. p. 47·5—49·5°, decomp. 100°, is prepared by direct addition of iodine to amylpropiolic acid, excess halogen being removed by sulphur dioxide. The *potassium* and *lead* salts are described; neither is very stable in solution. A basic *lead* salt was also obtained. The dihalogenated amylacrylic acids are less stable than the corresponding halogenated acrylic and crotonic acids. Attempts to separate the acids into isomerides by fractional distillation of the dibromo acid, fractional crystallisation of the di-iodo acid, and fractional crystallisation and precipitation of the salts all failed. The dibromo acid may be a mixture of two isomerides, one being in excess, and the crystals of the di-iodo acid may be a pure form. E. E. T.

Action of Carbonyl Chloride on Metallic Derivatives of Monosubstituted Acetylenes. I. Action of Carbonyl Chloride on Sodium *tert.*-Butylacetylide. M. P. Ivitzky (*Bull. Soc. chim.*, 1924, [iv], **35**, 357—360).—The sodium derivative of *tert.*-butylacetylene reacts readily with carbonyl chloride in ethereal solution yielding *trimethyltetrolyl chloride* [*γγ-dimethyl-*

Δ^{α}*-pentinoyl chloride*], $CMe_3{\cdot}C{:}C{\cdot}COCl$, b. p. 46·5—47·5°/16 mm., which, on hydrolysis, yields $\gamma\gamma$-dimethyl-Δ^{α}-pentinenoic acid, b. p. 106—107°/10 mm., m. p. 48—49°. The acid chloride can also react with a second molecule of the acetylide, and the unsaturated ketone, *bis-$\gamma\gamma$-dimethyl-Δ^{α}-butinenyl ketone*, $(CMe_3{\cdot}C{:}C)_2CO$, colourless crystals, m. p. 66·5°, is obtained as a by-product in the reaction. If the carbonyl chloride is added at once to the sodium *tert.*-butylacetylide, a violent reaction takes place, and after decomposition of the product with water, *tri-$\gamma\gamma$-dimethyl-Δ^{α}-butinenyl carbinol*, $(CMe_3{\cdot}C{:}C)_3C{\cdot}OH$, colourless crystals, m. p. 102·5°, is obtained. By the action of sodium *tert.*-butylacetylide on acetone a substance, m. p. 102·5°, was obtained in almost quantitative yield.
R. B.

Bauer Oil, the Higher-boiling Residue from Molasses Fusel Oil. A Source of Capric [Decoic] Acid. C. S. MARVEL and F. D. HAGER (*J. Amer. Chem. Soc.*, 1924, **46**, 726—730).—A dark reddish-brown oil, b. p. 130—235°/35 mm., obtained as a residue during the distillation of molasses fusel oil, consisted of the ethyl esters of decoic, lauric, myristic, and palmitic acids, and a little unsaponifiable matter. This forms an additional source for the preparation of decoic acid, which occurs only in small quantities in the common fats. [Cf. *B.*, 1924, 438.] C. J. S.

Glycerides of Fats and Oils. XI. Glycerides of Palm Kernel Oil. A. BÖMER and K. SCHNEIDER (*Z. Unters. Nahr. Genussm.*, 1924, **47**, 61—89).—Five almost pure mixed glycerides were isolated from a sample of palm kernel oil by repeated fractional crystallisation from acetone, and were identified as decoylomyristoolein, myristodilaurin, laurodimyristin, palmitodimyristin, and myristodipalmitin. The first two of these glycerides were present in considerable amount, the third only in small amount, and the last two in very small amount, comprising the most difficultly soluble glycerides in the oil. It is very unlikely that stearic acid is present in the glycerides of palm kernel oil, and hexoic acid was not present in the sample investigated. It is uncertain whether decoic acid was present or not. H. C. R.

Chemical Composition of Sesamé Oil. G. S. JAMIESON and W. F. BAUGHMAN (*J. Amer. Chem. Soc.*, 1924, **46**, 775—778).—Sesamé oil having the characteristics d_{25}^{25} 0·9187, n^{20} 1·4731, acid value 1·4, iodine value (Hanus) 110·8, saponification value 189·3, unsaponifiable matter 1·73%, acetyl value 9·8, Reichert-Meissl value 0·11, Polenske value 0·15, was found to contain the glycerides of the following acids in the proportions indicated: oleic (48·1%), linolic (36·8%), palmitic (7·7%), stearic (4·6%), arachidic (0·4%), and lignoceric (0·04%). C. J. S.

Oils and Fats from the Seeds of Indian Forest Plants. VI. Oil from the Seeds of *Aleurites montana*, Wilson. R. M. PARKER, M. G. RAU, W. A. ROBERTSON, and J. L. SIMONSEN (*Indian Forest Records*, 1923, **10**, 11—22).—The oil had the following characteristics: d_{15}^{15} 0·9467, n_D^{15} 1·494, acid value 3·4, saponification value 203, unsaponifiable matter 0·6%, iodine value 141·4, insoluble fatty acids 94% (solidifying point 54—54·5°). The principal fatty acid present in the oil was β-elæostearic acid (m. p. 73°). The α-isomeride was apparently completely absent. The β-elæostearic acid was brominated in chloroform solution and an unstable *dibromo* derivative (m. p. 95°) obtained. On bromination in acetic acid solution, a mixture of a solid and a liquid tetrabromo acid was obtained. The solid product, needles, m. p. 115°, was not identical with the tetrabromo acid from linolic acid. The liquid acids present in the oil were identified as oleic and linolic acids; linolenic acid was absent. H. C. R.

Oils and Fats from the Seeds of Indian Forest Plants. VII. Oil from the Seeds of *Salvia plebeia*, R. Br. M. G. Rau and J. L. Simonsen (*Indian Forest Records*, 1924, **10**, 23—26).—The ground seeds on extraction with cold benzene gave 11% of an oil having the following characters: d_{30}^{30} 0·934, n_D^{30} 1·4832, acid value 6·0, saponification value 195·0, unsaponifiable matter 0·02%, acetyl value nil, iodine value 131·1, Reichert Meissl value 1·3, solidification point of the insoluble fatty acids 10·5—11°. Stearic acid was the only saturated acid present. Linolenic acid, linolic acid, and oleic acid were identified in the oil. H. C. R.

Tung Oil. A. Eibner, O. Merz, and H. Munzert (*Chem. Umschau*, 1924, **31**, 69—82).—Tung oil contains 75% of glyceryl α-elæostearate, which changes under the influence of light into the solid geometrical isomeride, glyceryl β-elæostearate. Both the α- and the β-triglycerides increase in weight at about the same rate when exposed to the air in thin films. After standing for 10 months in a closed brown glass bottle, β-elæostearin became insoluble in acetone and no longer melted, but charred at about 265°. Both α- and β-elæostearic acids, m. p. 48° and 72°, respectively, were prepared from tung oil which had stood for some time, by extracting with ethyl alcohol and fractionally crystallising the extract from this solvent at about 0°. Another acid (m. p. 106·5°), giving the reaction of azelaic acid with ferric and mercuric chlorides, was obtained from the residue insoluble in cold alcohol, and is presumably a cleavage product obtained from elæostearic acid. The difference in the drying properties of α- and β-elæostearic acids was investigated by exposing thin layers of the acids to the air. After 8—10 days, the α-acid was transformed into a clear yellow syrup, whilst the β-acid remained unchanged for 14 days and was only transformed into a clear yellow, viscous syrup after 4 weeks' exposure. Only two of the three possible geometrical isomerides of elæostearic acid have been obtained. It is considered that the α-acid is probably the *cis-cis* form and the β-acid the *cis-trans* form. Bromination of both α- and β-acids yields the same tetrabromide (m. p. 114°). The transformation of the α into the β geometrical isomeride, on treatment with bromine, is considered to be a peculiarity confined to compounds containing two double linkings separated by two methylene groups, a constitution which explains the high reactivity of elæostearic acid. Evidence is adduced in favour of the view that the conversion of the α- and the β-acid plays very little part in the mechanism of the drying of tung oil, which appears to be a colloidal phenomenon involving transformation from the sol to the gel form rather than a case of molecular polymerisation. H. C. R.

Hydrate of Bismuth Lactate. E. MOLES and R. PORTILLO (*Anal. Fis. Quím.*, 1924, **22**, 133—143).—Bismuth lactate obtained by the action of lactic acid on bismuth hydroxide contains water of hydration corresponding to the formula $C_6H_9O_6Bi,7Aq$. In solution, it behaves as a non-electrolyte, as is shown by cryoscopic and conductivity determinations. The solution, on keeping, deposits the anhydrous salt which has a smaller solubility than the hydrated salt. The reaction appears to be autocatalytic. G. W. R.

Sebacic Acid. E. BŒDTKER (*J. Pharm. Chim.*, 1924, **29**, 313—319).—Ricinoleic acid, when distilled with an excess of sodium hydroxide, gives sebacic acid, octyl alcohol, methyl hexyl ketone, and a viscous, brown residue. From the latter have now been isolated stearic acid, m. p. 69·2°, an acid, m. p. 81—82°, which is either ricinic acid, $C_{18}H_{34}O_3$, or hydroxystearic acid, undecenoic acid, $C_{11}H_{20}O_2$ (formed by the pyrogenic decomposition of the ricinoleic acid), and finally an asphaltic resin. The maximum yield of sebacic acid (33 g. from 100 g. of ricinoleic acid) is obtained by heating sodium ricinoleate with one equivalent of sodium hydroxide. F. G. M.

Resolution of Racemic Malic Acid and the Preparation of *d*-Malic Acid. E. DARMOIS and J. PERIN (*Bull. Soc. chim.*, 1924, [iv], **35**, 353; cf. A., 1923, i, 299).—The *d*-malic acid obtained from active chlorosuccinic acid by treatment with silver nitrate according to Walden's process is now shown to be partly racemised, about 25% of the product consisting of the *l*-acid. By the addition of ammonium molybdate, it is possible to isolate successively the lævo- and dextro-rotatory forms of the ammonium dimolybdomalate, $2MoO_3,C_4H_6O_5,2NH_3$, the lævo-form crystallising first. Racemic ammonium dimolybdomalate does not appear to exist at the experimental temperatures, 16—20°, the crystals obtained when the compound is prepared from *r*-malic acid consisting of the *d*- and *l*-dimolybdomalate in equal proportions. A satisfactory method of converting the dimolybdomalonates into the corresponding malic acids has not yet been found, the product obtained from ammonium *l*-dimolybdomalonate being *l*-malic acid and not the *d*-form as was expected. R. B.

Resolution of Inactive Malic Acid into Optically Active Forms. H. D. DAKIN (*J. Biol. Chem.*, 1924, **59**, 7—12).—From a solution of cinchonine and inactive malic acid in molecular proportions in hot methyl alcohol or acetone, *cinchonine* l-*malate* separates in very good yield, and may be completely purified by crystallisation from methyl alcohol, or from water; from the [illegible] it separates in clear, hard prisms, m. p. 197—198°,

$[\alpha]^{19}_D$ +146° (in water). The methyl alcohol or acetone filtrate from the lævo salt is concentrated and water added occasionally; the residue is allowed to crystallise from water, when *cinchonine* d-*malate* (+$2H_2O$) is obtained as fine rosettes of clear, silky, prismatic needles, m. p. (hydrated) 106°, (anhydrous) 125—135°, $[\alpha]^{18}_D$ +153° (in water). On decomposition of the cinchonine salts with ammonia, *d*-malic acid, m. p. 99—100°, $[\alpha]^{19}_D$ +2·33°, and *l*-malic acid, m. p. 99—100°, $[\alpha]^{18}_D$ −2·31°, were obtained.

W. O. K.

Phosphor-Emetic [Potassium Phosphoryl Tartrate]. I. H. STERNLIEB (*Bull. Acad. Sci. Roumaine*, 1923, **8**, 211—214; cf. Costeanu, following abstract).—Crystals of potassium phosphoryl tartrate, $CO_2K{\cdot}CH(O{\cdot}PO){\cdot}CH(OH){\cdot}CO_2H,0{\cdot}5H_2O$, are prepared by dissolving 2 parts of phosphorus trioxide and 3 parts of potassium hydrogen tartrate in 16 parts of water and, with constant stirring, heating to the boiling point. The sparingly soluble, small, white crystals, having $[\alpha]^{15°}_D$ +80·62°, which separate, lose the water of crystallisation at 110°, and at 200° form a hygroscopic anhydride, m. p. 242°. S. K. T.

Emetics [Cæsium Antimonyl Tartrate].—N. D. COSTEANU (*Bull. Acad. Sci. Roumaine*, 1923, **8**, 215—218; cf. Sternlieb, preceding abstract).—Three methods are given for the preparation of the hitherto unknown *cæsium emetic* (*cæsium antimonyl tartrate*), $CO_2Cs{\cdot}CH(O{\cdot}SbO){\cdot}CH(OH){\cdot}CO_2H,0{\cdot}5H_2O$. (1) By the action of diantimonyl tartaric acid (prepared by dissolving freshly-precipitated antimony oxide in cold tartaric acid solution and precipitating with alcohol) on normal cæsium tartrate solution, partly precipitating with alcohol, warming the mixture and cooling again. (2) By the interaction of cæsium chloride and silver antimonyl tartrate. (3) By boiling a solution of cæsium hydrogen tartrate with antimony oxide.

Cæsium antimonyl tartrate forms transparent, orthorhombic prisms, *d* 2·27, [α] +79·21°, loses its water of crystallisation at 100°, and, at 200°, forms an anhydride. The aqueous solution dissolves iodine, any remaining undissolved assuming a golden colour; it yields precipitates with silver and lead nitrates, ferric chloride, and mineral acids. S. K. T.

Action of Triphenylmethyl Chloride on Free Sulphydro Groups. E. BILLMANN and N. V. DUE (*Bull. Soc. chim.*, 1924, [iv], **35**, 384—390; cf. A., 1905, i, 625; 1906, i, 625; 1908, i, 142).—The action of triphenylmethyl chloride or bromide on xanthylacetic acid proceeds in accordance with the scheme:

$$OEt{\cdot}CS{\cdot}S{\cdot}CH_2{\cdot}CO_2H + CPh_3Br \longrightarrow CPh_3{\cdot}S{\cdot}CO{\cdot}S{\cdot}CH_2{\cdot}CO_2H + EtBr$$
$$\longrightarrow COS + CPh_3{\cdot}S{\cdot}CH_2{\cdot}CO_2H.$$

The following compounds have been obtained: *Triphenylmethylthiolacetic acid*, $CPh_3{\cdot}S{\cdot}CH_2{\cdot}CO_2H$, brilliant pointed prisms, m. p. 162·5—163°, which is not decomposed by warm dilute sodium hydroxide, but on treatment with bromine yields dithiolacetic acid and triphenylmethyl bromide; α-*triphenylmethylthiolpropionic* *acid*, microscopic white crystals, m. p. 151°; β-*triphenylmethylthiolpropionic acid*, white, microscopic crystals, m. p. 208—209°; *triphenylmethylthiolsuccinic acid*, fine octahedra, m. p. 186—187° (decomp.).

In a similar way, the action of triphenylmethyl chloride on free xanthic acid in benzene solution yields triphenylmethyl xanthate, $CPh_3{\cdot}S{\cdot}CS{\cdot}OEt$, large, yellow crystals, m. p. 139°, in a 97% yield. Free thiolbenzoic acid in toluene solution gives triphenylmethyl thiobenzoate, $C_6H_5{\cdot}CO{\cdot}S{\cdot}CPh_3$, m. p. 187·5—188°, in 85% yield (cf. A., 1901, i, 636; 1913, i, 1335) and thiocyanic acid in ethereal solution gives an 89% yield of triphenylmethyl thiocyanate, $NCS{\cdot}CPh_3$, m. p. 137·5%. R. B.

Alleged Reduction of Carbon Dioxide to Formaldehyde by Hydrogen Peroxide, and the Assimilation Hypothesis of T. Thunberg. A. Bach and M. Monosson (*Ber.*, 1924, **57**, [*B*], 735—738; cf. A., 1923, i, 1271).—The production of traces of formaldehyde on distilling basic lead carbonate with hydrogen peroxide was confirmed. The authors show, however, that the formaldehyde is not produced from the lead carbonate itself, but from the small amounts of organic preservatives (*e.g.*, acetanilide) used to stabilise the hydrogen peroxide, which are catalytically oxidised by the latter in presence of lead. Control experiments using purified materials gave completely negative results, whilst the addition of a little acetanilide led at once to the production of formaldehyde. The addition of barbituric acid, however, gave no trace of formaldehyde. Thunberg's assimilation hypothesis is therefore devoid of foundation. [Cf. i, 606.] F. A. M.

Electrolytic Oxidation of Formaldehyde. C. del Fresno (*Anal. Fis. Quim.*, 1924, **22**, 121—132; cf. Müller and Hochstetter, A., 1914, ii, 615; Müller, A., 1920, i, 709).—The author has studied the electrolytic oxidation of formaldehyde in solutions of sodium hydroxide with electrodes of platinum, copper, and silver, respectively. Curves are drawn showing the relation between anode potential and current intensity. The results are in agreement with the theories of Müller. In each case where the anode potential exceeds a certain value the current intensity decreases, and at the same time there is a discontinuity in the potential, which becomes more positive. The passage of a current begins at much lower potentials in alkaline solutions containing formaldehyde than in solutions of sodium hydroxide alone. With electrodes of copper and silver, oxidation of formaldehyde occurs accompanied by evolution of hydrogen (dehydroxidation) at low potentials, whilst at high potentials, as is the case also with platinum electrodes, oxidation occurs without evolution of hydrogen. The mechanism of the oxidation is discussed. G. W. R.

Production of Acetone by the Action of Potassium Acetate on Acetic Anhydride. E. Luce (*Bull. Soc. chim.*, 1924, [iv], 35, 179—183).—The amount of acetone produced by refluxing acetic anhydride and potassium acetate for 30 hours at 170—180°

is not influenced by the presence of acetic acid. The yield of acetone is small, owing to polymerisation and to loss through carrying away by the carbon dioxide produced. The latter is prevented by special apparatus, and the yield then becomes 24% of the theoretical. No carbon monoxide is formed; sodium acetate cannot replace the potassium salt (cf. T., 1886, **49**, 317). Since the reaction is slow and at first no carbon dioxide is evolved, elevation of the temperature simply causing acetic anhydride to distil over; it probably follows the course $Ac_2O+Me\cdot CO_2K=(AcO)_2CMe\cdot OK=COMe_2+CO_2+Me\cdot CO_2K$. When potassium acetate is replaced by the butyrate, acetone and methyl propyl ketone are obtained. E. E. T.

Dihydroxyacetone. H. O. L. Fischer and H. Mildbrand (*Ber.*, 1924, **57**, [*B*], 707—710).—Dihydroxyacetone has been prepared in the unimolecular *form* [needles or rhombs, m. p. (indefinite) 65—71°] by the distillation of bimolecular dihydroxyacetone under greatly diminished pressure and immediate cooling of the distillate. It is converted by acetic anhydride and pyridine into the unimolecular diacetate, m. p. 42—45 [Dimroth and Schweizer (A., 1923, i, 745) give m. p. 46—47°]. With acetone in the presence of anhydrous copper sulphate, it yields the corresponding bimolecular *dïisopropylidene ether*, needles, m. p. 165·5—167·5°, to which the annexed constitution is ascribed. Freshly distilled dihydroxyacetone is converted by ethyl orthoformate in alcoholic solution in the presence of ammonium chloride into the corresponding *ethylcycloacetal*, $\left[\begin{array}{l}OH\cdot CH_2\cdot C(OEt)\cdot O—\\ \qquad\quad CH_2\end{array}\right]_2$, m. p. 126°. H. W.

Pennone [ββγγ-**Tetramethylpentane**-δ-**one**]. R. Locquin and W. Sung (*Compt. rend.*, 1924, **178**, 1179—1182; cf. A., 1923, i, 433, also Richard, A., 1911, i, 6).—In dehydrating ββγδ-tetramethylpentane-γδ-diol, only 6—7% of the substance is transformed into hexamethylacetone. The chief product (76%) is *ββγγ-tetramethylpentane-δ-one*, $C_9H_{18}O$, m. p. 63—64°, b. p. 167·5°/746 mm. (*oxime*, m. p. 125°, b. p. 215—220°; *semicarbazone*, m. p. 207—208°). On reduction by sodium and alcohol, the ketone, which the authors designate as *pennone*, yields the corresponding secondary alcohol, *pennol*, m. p. 50°, b. p. 179—180°. Oxidation of the ketone or alcohol yields *ααββ-tetramethylbutyric acid*, m. p. 200° (*ethyl* ester, a mobile liquid, b. p. 168—169°/746 mm.). H. J. E.

Reactions Relating to Carbohydrates and Polysaccharides. VIII. Electrolytic Reduction of Carbonyl Derivatives. H. Hibbert and R. R. Read (*J. Amer. Chem. Soc.*, 1924, **46**, 983—999).—Various ketones and aldehydes were reduced by an electrolytic method in order to compare the activities of the carbonyl group. The carbonyl derivative was added to an electrolyte (usually 2*N*-sulphuric acid with or without alcohol) in the cathode compartment, and caused a fall in the cathode potential varying with the ease or difficulty with which the substance underwent reduction. In the case of aldehydes, this depended on (*a*), whether saturated or unsaturated: the fall was 0·12 volt for *n*-butaldehyde and 0·58 volt for crotonaldehyde; (*b*) the length of the chain; (*c*) the spatial relation of the atoms: the values for acetaldehyde, propionaldehyde, *iso*butaldehyde, and *n*-butaldehyde were 0·30, 0·30, 0·17, 0·12 volt, respectively; (*d*) character of groups in molecule: substitution of hydrogen by hydroxyl is shown by comparing *n*-butaldehyde 0·12 volt, with acetaldol, 0·25 volt. Ketones brought about a much smaller effect: dimethyl, methyl ethyl, and methyl propyl ketone showed 0·06, 0·06, and 0·04 volt, respectively. To compare the "current efficiencies," which were found to run parallel to the lowering of cathode potentials, the hydrogen absorbed was plotted against the total hydrogen as measured in a coulombmeter in series with the experimental cell. The reduction products of crotonaldehyde were found to be different from those obtained by chemical reduction. The main fraction consisted of 2:3-*dimethyl*-Δ^5-cyclo*pentene*-1-*aldehyde*:

$$\begin{matrix} CH_2\text{——}CH \\ | \\ CHMe{\cdot}CHMe \end{matrix}\!\!>\!C{\cdot}CHO$$

, b. p. 170—175° (*semicarbazone*, white needles, m. p. 185—187°). Little or no dipropenyl glycol was formed. Dextrose could not be reduced to mannitol. The aldehydes investigated (apart from crotonaldehyde) were in all cases reduced to the corresponding alcohols, acetaldol to a glycol. The ketone reduction products were oily and had a pungent odour; they were not isolated. It is concluded that in the case of carbonyl derivatives such as the carbohydrates, anhydro-sugars, and polysaccharides, the determination of the two factors described results in values lying too close together to be of service as a means of distinguishing between the residual valencies of the carbonyl groups; and, further, that refinements in the measurements of the factors appear of little use owing to the limits imposed by the non-reproducibility of the cathode. A. C.

Course of the Mutarotation of Dextrose. H. v. Euler, K. Myrbäck, and E. Rudberg (*Ark. Kemi, Min., Geol.*, 1923, 8, No. 28, 1—9).—According to Euler and Hedelius (A., 1920, i, 712), the reaction constant for this change is 6×10^{-3} in a solution having p_H 5 at 20°, and measurements made by Michaelis give the value $6{\cdot}6 \times 10^{-13}$ for the acid dissociation of dextrose at the same temperature. From these results, the concentration of the intermediate product or of the reacting ions is calculated to be $3{\cdot}7 \times 10^{-8}$. Since Michaelis employed dextrose solutions containing α- and β-dextroses in equilibrium in the known proportions, the authors have carried out experiments to ascertain if α-dextrose behaves, with respect to salt-formation, differently from β-dextrose or from the equilibrated mixture; no appreciable difference is found in this regard. Further, the degree of hydrolysis of the dextrose-alkali salt varies inconsiderably with the temperature. [H. v. Euler and Rudberg, A., 1923, ii, 840.] T. H. P.

Action of Guanidine on Dextrose in the Presence and Absence of Oxygen. E. J. Witzemann (*J. Amer. Chem. Soc.*, 1924, [illegible]).—Morrell and Bellars (T., 1907, 91, 1010) have shown that guanidine is comparable with sodium and potassium hydroxides with regard to the velocity of hydrolysis of ethyl acetate. The results now described show that guanidine is also comparable with these bases in its action on dextrose both in the presence and absence of air or hydrogen peroxide. Guanidine causes polymerisation accompanied by yellowing more rapidly than potassium hydroxide, but this action is much less influenced by temperature than in the instance of the latter base. C. J. S.

Optical Behaviour of βε-Anhydroglucose, of βε-Anhydrogluconic Acid, and of βε-Anhydromannonic Acid. P. A. Levene (*J. Biol. Chem.*, 1924, **59**, 135—139).—Stereochemical considerations lead to the expectation that epichitose (βε-anhydroglucose) would not be able to form an oxide ring structure, and that it therefore exists in the aldehydic form. It is actually found that it is decolorised very rapidly by permanganate. Chitonic acid and chitaric acid do not exhibit mutarotation, probably because, likewise, lactone formation is not possible. W. O. K.

Preparation of α-Mannose. II. P. A. Levene (*J. Biol. Chem.*, 1924, **59**, 129—134).—A solution of mannose (100 g.) in water (25 c.c.) is cooled to 0°, and cooled glacial acetic acid (400 c.c.) is added. The crystals of α-mannose which separate are filtered after 4—5 hours, and subsequently extracted eight times with alcohol (80% by weight, 200 c.c., for each 100 g. of sugar). From optical observations on the mutarotation of α-mannose it is found that $K_1+K_2=0{\cdot}0054$, in 80% alcohol at 25°, and 0·0029 in water at 1·5°, where K_1 is the rate of conversion of the α- into the β-form, and K_2 the rate of the reverse reaction. From similar observations on β-mannose, $K_1+K_2=0{\cdot}0029$, in water at 1·5°, and 0·00575 in 80% alcohol at 25°. Measurements of solubility give $K_1=0{\cdot}00193$ and $K_2=0{\cdot}00041$. These results elucidate the discrepancy previously reported (Levene, this vol., i, 15). W. O. K.

α-Mannose Penta-acetate. P. A. Levene (*J. Biol. Chem.*, 1924, **59**, 141—144).—Acetylation of α-mannose in pyridine with acetic anhydride results in the formation of α-mannose penta-acetate, m. p. 64°, $[\alpha]_{D}^{17}$ +57·6°, identical with the penta-acetate obtained by Hudson and Dale (A., 1915, i, 502) by the action of zinc chloride on β-mannose penta-acetate. W. O. K.

Three Isomeric Crystalline Tetra-acetylmethyl-*d*-mannosides. J. K. Dale (*J. Amer. Chem. Soc.*, 1924, **46**, 1046—1051).—*α-Tetra-acetylmethyl-*d*-mannoside*, m. p. 65°, $[\alpha]_{D}^{20}$ +49·1°, was prepared by acetylating methyl-*d*-mannoside with acetic anhydride and sodium acetate. β-*d*-Mannose penta-acetate dissolved in glacial acetic acid saturated with hydrobromic acid yields a syrupy product containing bromine, which is converted by silver carbonate in the presence of methyl alcohol into *γ-tetra-acetylmethyl-*d*-mannoside*, m. p. 105°, $[\alpha]_{D}^{20}$ −26·6°. This compound possesses properties not generally characteristic of the acetylated glucosidic derivatives of the sugars. When subjected to alkaline hydrolysis, only three out of the four acetyl groups are removed, although the whole four are removed by acid hydrolysis. On treating its solution in methyl alcohol with hydrogen chloride, a rapid change in rotation occurs and an apparent equilibrium is reached in a few minutes at $[\alpha]_D^{20}$ +10·4°. The solution at this stage was neutralised, and yielded a third isomeride, β-*tetra-acetylmethyl*-d-*mannoside*, m. p. 162°, $[\alpha]_D^{20}$ −47·0°. Although the yield was only 7% of the theoretical, attempts to extract further crystalline substances were unsuccessful.

The close parallel in specific rotation and behaviour on hydrolysis between these isomerides and the three crystalline triacetylmethyl-*l*-rhamnosides recently prepared by Fischer, Bergmann, and Rahe (A., 1921, i, 94), is pointed out. A. C.

Isomeric Diacetonemannoses [Mannose Di*iso*propylidene Ethers]. P. A. Levene and G. M. Meyer (*J. Biol. Chem.*, 1924, 59, 145—149).—Methylation of diacetonemannose by methyl iodide and silver oxide resulted in the formation of a *methyldiacetonemannose*, b. p. 115°/1·2 mm., $[\alpha]_D^{20}$ +23° (in *s*-tetrachloroethane), which on hydrolysis by alcoholic hydrochloric acid yields mannose. Methylation by sodium and methyl iodide (cf. Freudenberg and Hixon, A., 1923, i, 1179) results in the formation of a methyldiacetonemannose, $[\alpha]_D^{20}$ −42·2° (in *s*-tetrachloroethane). These may be more or less pure samples of the α- and β-forms of α-methyl-βγεζ-diacetonemannoside, as from α-methylmannoside a diacetone-α-methylmannoside, b. p. 105°/0·5 mm., $[\alpha]_D^{20}$ +34·9°, was obtained. W. O. K.

Specific Rotations of Hexonic and α-Aminohexonic Acids and of their Salts. P. A. Levene (*J. Biol. Chem.*, 1924, 59, 123—127).—The following specific rotations are given: gluconic acid, $[\alpha]_D^0$ 0·0°; mannonic acid, $[\alpha]_D^0$ +15·6°; gulonic acid, $[\alpha]_D^0$ +1·6°; galactonic acid, $[\alpha]_D^0$ −8·0°; allonic acid, $[\alpha]_D^0$ −10·0°; altronic acid, $[\alpha]_D^0$ +8·0°; whilst only sufficient idonic acid was available to ascertain that it is in all probability dextrorotatory. On comparison of these figures with those previously given for their sodium salts, phenylhydrazides, and amides, it appears that the rotation of the free acid is in the opposite sense from that of the derivatives. The following figures are also given: chitosaminic acid, $[\alpha]_D^0$ −1·3° in 5% sodium hydroxide solution (c = 5·0%), −15° in 2·5% hydrochloric acid; epichitosamic acid, $[\alpha]_D^0$ −5·0° in 5% sodium hydroxide solution (c = 5%), +10° in 2·5% hydrochloric acid solution; "dextro-*d*-xylos-α-aminohexonic acid," $[\alpha]_D^0$ −16° in 5% sodium hydroxide solution (c = 2·5%), +14° in 2·5% hydrochloric acid solution; "lævo-*d*-xylos-α-aminohexonic acid," $[\alpha]_D^0$ +2·0° in 5% sodium hydroxide solution (c = 2·5%), −11° in 2·5% hydrochloric acid solution; chondrosaminic acid, $[\alpha]_D^0$ −15° in 5% sodium hydroxide solution (c = 2·5%), −17° in 2·5% hydrochloric acid solution; epichondrosaminic acid, $[\alpha]_D^0$ −1·8° in 5% sodium hydroxide solution (c = 2·5%), +8·0° in 2·5% hydrochloric acid solution, "dextro-*d*-ribos-α-aminohexonic acid," +2·0° in 5% sodium hydroxide solution (c = 2·5%), +12·5° in 2·5% hydrochloric acid solution; "lævo-*d*-ribos-α-aminohexonic acid," $-15°$ in 5% sodium hydroxide solution ($c = 2·5\%$), $-26·0°$ in 2·5% hydrochloric acid solution. W. O. K.

Relation between Rotatory Power and Structure in the Sugar Group. IV. Two Isomeric Crystalline Hexa-acetates of *d*-α-Mannoheptose. C. S. Hudson and K. P. Monroe (*J. Amer. Chem. Soc.*, 1924, **46**, 979—983).—Acetylation of *d*-α-mannoheptose by adding the sugar to gently boiling acetic anhydride containing sodium acetate resulted in the isolation of a crystalline *hexa-acetate*, m. p. 106°, $[\alpha]_D^{20}$ $+24·2°$ in chloroform. It was transformed by hot acetic anhydride and zinc chloride into a strongly dextrorotatory syrup from which a second *hexa-acetate*, m. p. 139—140°, $[\alpha]_D^{20}$ $-31°$ in chloroform, crystallised. From a comparison with the dextrose penta-acetate, it is inferred that the first hexa-acetate is a β-form and that the main (strongly dextrorotatory) amorphous product is the α-form. Comparison of the hexa-acetates with the galactose penta-acetates (A., 1916, i, 546) indicates that the compound, m. p. 106°, and the strongly dextrorotatory amorphous product are probably β- and α-forms of the butyleneoxide type, whereas the substance, m. p. 139—140°, is a β-form of some other type. A. C.

Polysaccharides. VIII. Molecular Structure of β-Hexa-amylose. J. C. Irvine, H. Pringsheim, and J. Macdonald (*J. Chem. Soc.*, 1924, **125**, 942—947).—Karrer and Bürklin's statement (A., 1922, i, 435) that triamylose and β-hexa-amylose are identical is disproved by the conversion of the latter on exhaustive methylation into the crystalline β-*hexa(trimethylamylose)*, $C_{54}H_{96}O_{30}$, m. p. 102—105°, thus confirming the view of Pringsheim and Dernikos (A., 1922, i, 632). β-Hexa(trimethylamylose) on hydrolysis in methyl-alcoholic solution containing 1% of hydrogen chloride gave an equilibrium mixture of α- and β-trimethylmethylglucoside, which on further hydrolysis in 8% aqueous hydrochloric acid gave only 2 : 3 : 6-(βγζ-)trimethylglucose.
F. G. M.

Synthesis of Amygdalic Acid from Gentiobiose. G. Zemplén (*Ber.*, 1924, **57**, [*B*], 698—704).—Gentiobiose octa-acetate is converted by successive treatment with methyl-alcoholic sodium methoxide solution, sodium hydroxide, and methyl sulphate, and finally with silver oxide and methyl iodide, into heptamethyl methylgentiobioside, long, colourless needles, m. p. 109°, $[\alpha]_D^{11}$ $-22·39°$ in water, $[\alpha]_D^{16·5}$ $-20·89°$ in alcohol [Haworth and Wylam (T., 1923, **123**, 3124) give m. p. 106°, $[\alpha]_D$ $-33·9°$ in water, $-29·9°$ in alcohol]. On hydrolysis, it yields 2 : 3 : 5-trimethyl β-methylglucoside and 2 : 3 : 5-trimethylglucose. Gentiobiose octa-acetate is transformed by glacial acetic and hydrobromic acids in the presence of chloroform into acetobromogentiobiose,

$$C_{12}H_{14}O_3(OAc)_7·Br,$$

m. p. 131—133·5°, $[\alpha]_D^{19}$ $+111·8°$ in chloroform, which is converted by silver *dl*-mandelate into *hepta-acetylgentiobiosidyl mandelate*, $C_{12}H_{14}O_{11}Ac_7·CO·CH·PhOH$, small, colourless needles, m. p. 209° (decomp.) after softening at 205°, $[\alpha]_D^{17·5}$ $-9·73°$ in chloroform, and hepta-acetylamygdalic acid, m. p. about 90°, $[\alpha]_D^{15}$ $+6{\cdot}25°$ or $+10{\cdot}55°$ in chloroform. In its main features, synthetic hepta-acetylamygdalic acid closely resembles the product derived from amygdalin, but an exact comparison is rendered difficult by the amorphous nature of both compounds. A wide discrepancy is observed only in the specific rotation, which is attributed to the incomplete racemisation of the mandelic complex in the conversion of amygdalin into hepta-acetylamygdalic acid and to a partial resolution of silver *dl*-mandelate into its active components during the preparation of the synthetic acid (cf. Karrer and co-workers, A., 1921, i, 260). H. W.

Starch Grains. L. Rosenthaler (*Schweiz. Apoth.-Ztg.*, 1923, **61**, 654—659; from *Chem. Zentr.*, 1924, i, 451—452).—Starch grains from different plants may in some cases be distinguished by their behaviour towards methylene-blue, naphthylene-blue, and neutral-red, respectively. Observations are also recorded on the behaviour of different kinds of starch grains towards peptising reagents, acids, and alkalis. Whilst the results are of value for analytical purposes, they are nevertheless in many cases influenced strongly by experimental conditions. G. W. R.

Iodo Compounds of Simple αβ-*cyclo*Acetals of the Type of Starch Iodide. M. Bergmann (*Ber.*, 1924, **57**, [*B*], 753—755).—A solution of acetolmethyl*cyclo*acetal, $\left(\mathrm{OMe{\cdot}CMe}<\overset{\mathrm{CH_2}}{\underset{\mathrm{O}}{|}}\right)_2$, in methyl alcohol is converted by iodine and potassium iodide below 0° into the *compound* $C_8H_{16}O_4I_4,KI$, very unstable, bluish-black prisms, m. p. 50—52° when rapidly heated. The methyl*cyclo*acetal of acetoin gives a similar, but even less stable, *compound*, dark, steel-blue prisms. The formation of starch iodide is attributed to the presence in starch of similar oxygen rings, which cause addition of iodine and potassium iodide owing to their pronounced residual affinity. The polyamyloses do not behave in this manner. H. W.

Polymerisation of the Cellulose Molecule. P. Bary (*Compt. rend.*, 1924, **178**, 1159—1161).—A theoretical paper in which the two different types of reaction undergone by cellulose involving (*a*) no depolymerisation and a colloidal resultant, or (*b*) depolymerisation with a resultant which is less colloidal in its nature than cellulose, are considered. Cellulose is represented, not as $(C_6H_{10}O_5)_m$, but as $(C_6H_{10}O_5)_m,H_2O$, where *m* is very large, and the suggestion is put forward that hydrolysis and depolymerisation are effected by hydration of one of the oxygen linkings in the unit structure of the molecule. H. J. E.

Cellulose in Coal. F. Schulz and J. Hamackova (*Bull. Soc. chim.*, 1924, **35**, [iv], 183—187).—Cellulose was extracted from various recent lignites by Schorger's method (*J. Ind. Eng. Chem.*, 1917, 9, 556). The maximum content was 12% (referred to the weight of lignite less moisture and ash). The cellulose, a greyish-white mass in the crude state, was recognised by hydrolysis to a hexose and by conversion to cellobiose octa-acetate. Analyses showed that only in exceptional cases does the cellulose of wood remain unaltered, on the conversion of the latter into coal, up to the tertiary geological age. Other coals and lignites yielded no trace of cellulose. E. E. T.

Effect of 5*N*-Nitric Acid on Cellulose, Dextrose, Natural and Artificial Humic Acids, and Lignin. H. TROPSCH and A. SCHELLENBERG (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 257—262; from *Chem. Zentr.*, 1924, i, 562).—The action of 5*N*-nitric acid on natural and artificially prepared humic acids and on lignin is similar, nitrophenolic substances occurring amongst the products of reaction. Cellulose and dextrose behave differently. Humic acid artificially prepared from sugar is more readily attacked than natural humic acid and lignin. G. W. R.

[Esterification and Mercerisation of Cellulose.] R. O. HERZOG and G. LONDBERG (*Ber.*, 1924, **57**, [*B*], 750; cf. this vol., i, 373).—The authors' inability to obtain a monoacetate or monobenzoate of cellulose is due to the fact that further esterification occurs more rapidly in the altered layers than does monoacylation in the deeper layers. H. W.

Acetylation of Lignin. E. HEUSER and W. ACKERMANN (*Cellulosechemie*, 1924, **5**, 13—21; 30–31).—Lignin was obtained by treating resin-free wood meal with 41·2% hydrochloric acid; the product contained 13% of methoxyl and was free from residues of pentosan. This was acetylated by heating with acetic anhydride in the presence of pyridine; the acetyl value increased up to a maximum corresponding with 32·5% of combined acetic acid and then decreased on further heating owing to hydrolysis of the ester. Acetylation with acetyl chloride gave substantially identical results. Acetic anhydride alone gave inferior acetylation values as compared with those obtained in the presence of pyridine; addition of sodium acetate was still less favourable to esterification. Much more rapid esterification was effected by a mixture of acetic anhydride and nitric acid, and the same maximum limit of acetyl value was attained. On further treatment, this acetyl value decreased as before, but subsequently increased up to 42·5% owing to hydrolysis and re-acetylation of groups originally combined as methoxyl. The acetyl-lignin esters obtained were lighter in colour than the original lignin. Natural lignin existing in wood probably contains three hydroxyl groups on Klason's formula; the triacetate, $C_{41}H_{37}O_{11}(OAc)_3$, should contain 20·07% of combined acetic acid, as against 17·8% calculated from the authors' equilibrium value duly corrected. J. F. B.

Humic Acids. I. Method of Preparation. H. TROPSCH and A. SCHELLENBERG (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 191—195; from *Chem. Zentr.*, 1924, i, 600).—Rosenthal coal used for the preparation of humic acids contained 3·7% of material extractable by benzene. The ethyl alcohol extract (18·9%) contained 55% of humic substances. The humic acid used in subsequent investigations was obtained as follows. The coal was first extracted repeatedly with benzene and ethyl alcohol and the residue treated with 1% hydrochloric acid, after which it was shaken with 2*N*-sodium hydroxide. The alkaline solution was separated by filtration and centrifuging, and the humic acids were precipitated by acidifying with hydrochloric acid. The precipitate was collected and washed with water to the stage of incipient sol formation. The yield of humic acid was 60%, having the composition carbon 54·7%, hydrogen 3·0%, and ash 10·2%. G. W. R.

Humic Acids. II. Products of Alkali Fusion and Heating under Pressure. H. Tropsch and A. Schellenberg (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 196—213; from *Chem. Zentr.*, 1924, i, 600—601; cf. preceding abstract).—Humic acid (40 g.) obtained from bituminous coal was heated with potassium hydroxide (160 g.) and water (100 c.c.) at 240—300°. Humic substances were obtained in 40—50% yield. Steam distillation of the acid solution gave 3% of volatile acids, principally acetic acid together with a little formic acid, and small quantities of neutral reducing compounds. The ethereal extract contained *iso*phthalic acid, and hydroxy*iso*phthalic acid or hydroxyterephthalic acid. Oxalic acid was obtained from the residue after ether extraction. Heating humic acid under pressure with 10*N*-potassium hydroxide for 140 hours at 150° yielded 52% of humic substances soluble in alkali, containing carbon 47·9%, hydrogen 2·6%, and ash 26·7%. From these products, after acidification, acetic acid and formic acid were isolated by steam distillation, and oxalic acid by extraction with ether. *m*-Hydroxybenzoic acid and 5-hydroxy*iso*phthalic acid were also obtained. G. W. R.

Humic Acids. III. Action of Nitric Acid on Humic Acids. H. Tropsch and A. Schellenberg (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 214—234; from *Chem. Zentr.*, 1924, i, 601—602; cf. preceding abstracts).—Humic acid from coal is rapidly attacked by 5*N*-nitric acid at 60°, and by prolonged heating the material goes into solution with the exception of 4—9% of solid, brown residue. Oxalic acid and certain strongly acid substances having the character of nitrophenols are obtained. Reduction of these nitro compounds gives black, humic substances. From the ethereal extract in certain cases, 5% (calculated on the original humic acid) of *trinitrodihydroxybenzene* is obtained. It forms yellow needles, m. p. 267° (decomp.). On drying in a vacuum, water of crystallisation is lost at 80°, and the composition is then given by the formula $C_6H_3O_8N_3,0{\cdot}5H_2O$. A crystalline *tin* double salt is obtained on reduction with tin and hydrochloric acid; it forms thick, well-formed crystals. On attempting to isolate the amino compound, decomposition takes place with formation of black, humic substances. The products of reaction of humic acid with nitric acid (*d* 1·4) or with 2·5*N*-nitric acid are similar. With nitric acid (*d* 1·5), however, nitrohumic acid is obtained. The action of 5*N*-nitric on the humic acid prepared from quinol is more energetic than is the case with humic acid prepared from natural products. Oxalic acid and substances of the character of nitrophenols are obtained. Humic acid from sugar gives, with 5*N*-nitric acid at room temperature, a red, amorphous substance similar to the nitrohumic acid obtained from natural humic acid by the action of nitric acid (*d* 1·5). With nitric acid (*d* 1·5), sugar humic acid yields 20% of substances of the character of nitrophenols. G. W. R.

Humic Acids. IV. Effect of certain Reagents on Humic Acids. H. TROPSCH and A. SCHELLENBERG (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 235—247; from *Chem. Zentr.*, 1924, i, 602; cf. preceding abstracts).—Humic acid from coal yields, with 72% sulphuric acid, 87·5% of humic substances, of which 22% is soluble in alcohol; 11·4% of volatile acids, including formic acid and acetic acid, and 1·8% of an orange-red, lacquer-like substance. Hydrochloric acid reacts in a similar manner. By chlorination of humic acid suspended in *s*-tetrachloroethane, substances containing 18 to 30·8% of chlorine are obtained. Among the products of reaction of potassium chlorate and hydrochloric acid on humic acid is hexachloroethane. G. W. R.

Humic Acids. V. Dry Distillation of Humic Acid and its Alkaline Derivatives. H. TROPSCH and A. SCHELLENBERG (*Ges. Abh. Kenntn. Kohle*, 1921, **6**, 248—256; from *Chem. Zentr.*, 1924, i, 603; cf. preceding abstracts).—Dry distillation of humic acid at 525° and 0·8—5·1 mm. yields 57·5% of carbonaceous residue and gaseous products, including steam, carbon dioxide, and acetic and formic acids. Tarry substances were not obtained in the distillate. Similar products were obtained by distillation at 300° under atmospheric pressure. The humic substance obtained by heating humic acid with 10*N*-potassium hydroxide at 150° under pressure yields similar products on distillation. The substance obtained by heating humic acid with potassium hydroxide at 300° behaves differently on distillation in that it yields a certain amount of tar both at atmospheric and under reduced pressures. From the products of distillation under reduced pressure, a wax-like substance having m. p. 62° is obtained, the composition of which corresponds with a ketone, $C_{47}H_{94}O$. Distillation of humic acid with zinc dust gives, in addition to gaseous products and an aqueous distillate, a certain amount of oil having b. p. 80—130°, which by the action of nitric acid yields a heavy oil having the odour of nitrobenzene. Among the products of the distillation of humic acid with zinc dust in a current of hydrogen is an oil having the odour of pyridine and quinoline. G. W. R.

Electrolytic Reduction of Acid Oximes. M. ISHIBASHI (*Trans. Amer. Electrochem. Soc.*, 1924, **45**, 335).—γ-*iso*Nitrosovaleric acid is so easily hydrolysed in acid solution that it cannot be reduced chemically to the corresponding amine. An 84% yield of the latter is, however, obtained by electrolytic reduction, employing a current density of 2 amp. per sq. dm., a temperature of 3—5°, and a sulphuric acid concentration of less than 5%. The amine from α-*iso*nitrosopropionic acid is obtained in 95% yield with a current density of 4·5 amp. per sq. dm., a temperature of 7—10°, and an acid concentration of 8%.

W. T. K. B.

Trialdehyde Compounds of Primary Amines. M. BERGMANN and A. MIEKELEY (*Ber.*, 1924, **57**, [*B*], 662—664; cf. Bergmann, Jacobsohn, and Schotte, this vol., i, 19).—Aliphatic aldehydes combine with primary amines to give trialdehyde compounds of the type $R\cdot CH<^{O\cdot CHR}_{O\cdot CHR}>NR'$; the property is not shared by benzaldehyde.

Triformaldehyde-ethylamine, ($R=H$; $R'=Et$), b. p. 62—64°/42 mm. (*picrate*, m. p. 75°), is prepared by the gradual addition of ethylamine to a large excess of well-cooled, aqueous formaldehyde solution (30%). *Triacetaldehyde-ethylamine* is a colourless, unstable liquid, b. p. 59—60°/15 mm. Allylamine and formaldehyde give the relatively stable *triformaldehyde-allylamine*, b. p. 38—40°/1·5 mm., together with compounds richer in aldehyde. *Triacetaldehyde-allylamine* is a colourless, exceedingly unstable liquid, b. p. 48—50°/2·5 mm. Benzaldehyde and allylamine give *benzylidene-allylamine*, b. p. 96°/12 mm., which is transformed by bromine into *benzylidene-βγ-dibromopropylamine*, m. p. 36—37°. H. W.

Action of Secondary Amines on Alkyl Chlorosulphonates. M. DÉLÉPINE and R. DEMARS (*Bull. Sci. Pharmacol.*, 1923, **30**, 577—599; from *Chem. Zentr.*, 1924, i, 415; cf. A., 1922, i, 634).—Dialkylaminosulphonic acids or their esters might be expected to be formed by the action of secondary amines on alkyl chlorosulphonates according to the equation:

$$2RR'NH+Cl\cdot SO_2\cdot OR''=RR'N\cdot SO_2\cdot OR''+NHRR',HCl.$$

Actually, however, compounds of the betaine type are obtained which may be considered as anhydrides of trialkylammonium hydroxide sulphonic acids. Their formation from dialkylaminosulphonic acids may be thus represented: $RR'N\cdot SO_2\cdot OR''\longrightarrow$  $RR'R''N<^{SO_2}_{O}$ $\longleftarrow RR'R''N(OH)\cdot SO_2\cdot OH$. They are colourless neutral compounds which hydrolyse slowly with alkalis or acids to tertiary amines and sulphuric acid, behaving in this respect like the compounds formed from sulphur dioxide and tertiary amine oxides or hydroxylamines. *Trimethylammonium hydroxide N-sulphonic anhydride*, Me_3NSO_3, from dimethylamine and methyl chlorosulphonate, forms shining needles, m. p. above 200° (decomp.). It is also formed from sulphur dioxide and trimethylamine oxide. *Dimethylethylammonium hydroxide sulphonic anhydride*, Me_2EtNSO_3, has m. p. 131—133°, and *methyldipropylammonium hydroxide sulphonic anhydride*, m. p. 120—121°. G. W. R.

Constitution of Galegine. G. TANRET (*Bull. Soc. chim.*, 1924, [iv], **35**, 404—405; cf. A., 1914, i, 859).—One of the two open-chain structures advanced for galegine by Barger and White (this vol., i, 272) has been suggested previously by the author (Thesis, Paris, 1917). R. B.

Catalytic Decomposition of the Formic Amides. A. Mailhe (*Bull. Soc. chim.*, 1924, [iv], **35**, 363—365).—The primary amides of the formic acid series are dehydrated in contact with nickel at 400°, yielding the corresponding nitrile. The water formed in the reaction hydrolyses part of the unchanged amide to ammonia and the carboxylic acid, which in the presence of active nickel is decomposed into gaseous products and carbon.

R. B.

Preparation of Diethylchloroacetamide. Société Chimique des Usines du Rhône (Brit. Pat. 209706).—Diethylchloroacetyl chloride, b. p. 93°/70 mm., obtained by chlorinating diethylacetyl chloride at about 100°, is shaken with excess of ammonia or of a compound evolving ammonia (*e.g.*, ammonium carbonate). The diethylchloroacetamide produced forms white flakes, m. p. 58°, and possesses valuable soporific properties. W. T. K. B.

The Oxime of Mesoxamide (Oximinomalonamide) and some Allied Compounds. V. Structural- and Stereo-isomerism in the Methyl Ethers of the *p*-Tolyl Derivatives. A. Plowman and M. A. Whiteley (*J. Chem. Soc.*, 1924, **125**, 587—604; cf. *ibid.*, 1922, **121**, 2110).—Investigations of the ethers of alkyl- and aryl-substituted derivatives of oximinomalonamide have now been extended to the ethers of the *p*-tolyl derivatives, in which the stable yellow form appears to possess the *N*-ether structure. The yellow tautomeride of oximinomalon-*p*-toluidide, yellow scales, m. p. 170—171°, is obtained from mesox-*p*-toluidide and hydroxylamine under conditions (dilute alcoholic solution) which indicate that it possesses the *iso*oxime structure,

$$(C_7H_7\cdot NH\cdot CO)_2C<\genfrac{}{}{0pt}{}{O}{NH},$$

whereas the colourless tautomeride, thin needles, becoming yellow at 150°, m. p. 170—171°, is formed under different conditions (absolute alcoholic solution) pointing to the oxime structure, $(C_7H_7\cdot NH\cdot CO)_2C{:}NOH$. Of the two *methyl ethers* of oximino-malon-*p*-toluidide, the colourless stable *isomeride*, m. p. 171° [*hydrate*, $(C_7H_7\cdot NH\cdot CO)_2C(OH)\cdot NH\cdot OH$, m. p. 196°] from its formation from the hydrated form of mesox-*p*-toluidide and α-methylhydroxylamine must be regarded as the *O*-ether, whilst the structure of the yellow *isomeride*, m. p. 182° (decomp.), is established as the *N*-methyl ether by its hydrolysis to β-methylhydroxylamine and mesox-*p*-toluidide, and by its synthesis from the same two compounds. Further work on oximinomalonmono-*p*-tolylamide has led to the isolation of three yellow and two colourless *isomerides*. The original yellow isomeride (α), m. p. 184°, is converted into a colourless isomeride (β), m. p. 157°, by spontaneous evaporation from alcohol, and into a second colourless isomeride (β′), m. p. 175°, by the action of moist hydrogen chloride in the presence of chloroform; each of these colourless isomerides yields a corresponding yellow tautomeride (γ and γ′) when crystallised from non-hydroxylic solvents, melting at the same temperature as the parent colourless compound. On treatment with phosphorus pentachloride the β- and γ-isomerides yield *p-tolyloxamidonitrile*, $C_7H_7\cdot NH\cdot CO\cdot CN$, colourless needles, m. p. 178°, together with carbon dioxide, a reaction which indicates that they are the two structural forms of *anti-p*-tolylmesoxamideoxime, the coloured γ-isomeride possessing the *iso*oxime structure,

$$\begin{matrix} C_7H_7\cdot NH\cdot CO \\ NH_2\cdot CO \end{matrix}\!\!>C<\!\!\begin{matrix} NH \\ | \\ O \end{matrix}$$

. On treatment with phosphorus pentachloride the β′- and γ′-tautomerides undergo the normal Beckmann change and yield oxamide, carbon dioxide, and *p*-toluidine. They are therefore regarded as the structural isomerides of *syn-p*-tolylmesoxamideoxime, the true oxime structure, $NH_2\cdot CO\cdot C(:NOH)\cdot CO\cdot NH\cdot C_7H_7$, being assigned to the colourless β′-isomeride. The α-isomeride is the most stable isomeride and forms the sole product of the action of nitrosyl chloride on malonmono-*p*-toluidide. It yields the same ethers as the β- and γ-forms, and is similarly decomposed by the action of phosphorus pentachloride; it probably possesses a nitrone structure,

$$C_7H_7\cdot NH\cdot CO\cdot C(:NHO)\cdot CO\cdot NH_2.$$

The action of methyl iodide on the α-, β-, and γ-isomerides in the presence of silver oxide yields an *O-methyl ether*, colourless needles, m. p. 204°, a second colourless *ether*, flat needles, m. p. 155°, being obtained from the β′- and γ′-isomerides under similar conditions. The structure of these isomeric ethers as the *anti-* and *syn*-forms, respectively, of oximinomalonmono-*p*-toluidide,

$$C_7H_7\cdot NH\cdot CO\cdot C(:NOMe)\cdot CO\cdot NH_2,$$

is deduced from the synthesis of the isomeride, m. p. 204°, by the condensation of α-methylhydroxylamine hydrochloride in aqueous alcoholic solution with *mesoxmono-p-toluidide*,

$$C_7H_7\cdot NH\cdot CO\cdot CO\cdot CO\cdot NH_2,$$

m. p. 222° (decomp.), [*hydrate*, $C_7H_7\cdot NH\cdot CO\cdot C(OH)_2\cdot CO\cdot NH_2$, colourless plates, m. p. 222°, decomp., *phenylhydrazone hydrate*, colourless needles, yellow at 165°, m. p. 193°, *phenylhydrazone*, yellow needles, m. p. 193°], the hydrated form,

$$C_7H_7\cdot NH\cdot CO\cdot C(OH)(NH\cdot OMe)CO\cdot NH_2,$$

colourless needles, m. p. 179° (decomp.), being produced intermediately. Methylation with diazomethane converts the α-, β-, and γ-isomerides of oximinomalonmono-*p*-toluidide into an *N-methyl ether*, bright yellow, felted needles, m. p. 200° (decomp.), the β′- and γ′-isomerides yielding a second yellow *isomeride*, m. p. 150°, decomp. (*hydrate*, colourless needles). The structure of these yellow isomerides as *N*-methyl ethers of the *anti-* and *syn*-forms, respectively, of oximinomalonmono-*p*-toluidide is indicated by their hydrolysis with moist hydrogen chloride to the hydrated form of the corresponding ketone, mesoxmono-*p*-toluidide, from which a small quantity of the yellow isomeride, m. p. 200°, is formed by the action of β-methylhydroxylamine, the main product of this latter reaction being a colourless additive compound,

$$C_7H_7\cdot NH\cdot CO\cdot C(OH)(N_2Me\cdot OH)\cdot CO\cdot NH_2,$$

flat needles, m. p. 174° (decomp.), which has hitherto resisted dehydration.

Acetylation of the five isomerides of oximinomalonmono-*p*-toluidide yielded one of two colourless *acetyl* derivatives, m. p. 132° and 165°, respectively. The former is obtained from the α-oximino compound, the latter from the β′- and γ′-isomerides, the β- and γ-isomerides yielding a mixture from which only the acetyl derivative, m. p. 165°, could be isolated. On hydrolysis the latter substance yields the β′-oximino compound, whilst the compound melting at 132° yields a mixture of the α- and β-isomerides. The acetyl derivatives are accordingly regarded as acetates of the *syn-* and *anti*-type, respectively. R. B.

Thermal Decomposition of Allophanic Esters. J. Grandière (*Bull. Soc. chim.*, 1924, [iv], **35**, 187—196).—The following new esters were prepared by Béhal's method (A., 1919, ii, 301): *allophanates* of ethylpropylcarbinol (m. p. 185·5°); ethylbutylcarbinol (m. p. 187°), methyldiethylcarbinol (m. p. 152°), triethylcarbinol (m. p. 156°), methylethylpropylcarbinol (m. p. 148°), methylethylbutylcarbinol (m. p. 130°), Δ^{α}-penten-γ-ol (m. p. 155°), *o*-methyl*cyclo*hexanol (m. p. 177°), furyl alcohol (m. p. 167·5°), *o*-chlorophenol (m. p. 179°), glycol chlorohydrin (m. p. 182·5°).

On heating to 20° or 30° above the melting point most allophanic esters decompose into the alcohol and cyanuric acid, together with a small quantity of cyanic acid which reacts with the alcohol to give the corresponding urethane and allophanate. The esters of tertiary alcohols behave differently; a hydrocarbon of the ethylene series is evolved and allophanic acid probably formed as an intermediate product, but decomposes to carbamide, which immediately loses ammonia, both substances being unstable at the decomposition temperature of the ester. A certain amount of the alcohol and cyanuric acid is also formed.

The allophanates of geraniol, rhodanol, and citronellol decompose at 180—200° into carbon dioxide, ammonia, cyanuric acid, the alcohol, and a hydrocarbon, together with a brown, viscous liquid which, on hydrolysis, yields a small quantity of the corresponding alcohol. The allophanic esters of furyl and cinnamyl alcohols decompose into ammonia and carbon dioxide, leaving a resinous residue.

It is suggested that the behaviour of the allophanates of tertiary alcohols will serve for the detection of these alcohols (cf. A., 1919, ii, 301). E. E. T.

Isomeric Modifications of Methyleneaminoacetonitrile and their Biological Significance. T. B. Johnson and H. W. Rinehart (*J. Amer. Chem. Soc.*, 1924, **46**, 768—774).—Further investigation of the methyleneaminoacetonitriles, m. p. 129° and 86°, obtained by Klages (A., 1903, i, 469) has shown that they are structural isomerides having the formula $C_9H_{12}N_6$. The two compounds have different crystalline forms, behave differently on hydrolysis, and the one cannot be transformed into the other. The compound, m. p. 129°, for which the designation α-hydroformamine cyanide is proposed, forms orthorhombic crystals; β-hydroformamine cyanide, m. p. 86°, forms monoclinic crystals. C. J. S.

Deaminisation. III. Evidence of the Existence of Aliphatic Diazonium Salts from the Formation of Chloro-oximino Compounds. G. S. SKINNER (*J. Amer. Chem. Soc.*, 1924, **46**, 731—740).—The formation of ethyl chloro-oximinoacetate from the hydrochloride of ethyl aminoacetate and nitrous acid at low temperatures is presented as evidence of the existence of an aliphatic diazonium salt. It is believed to be produced according to the scheme: $NH_2{\cdot}CH_2{\cdot}CO_2Et,HCl \xrightarrow{+HNO_2} Cl{\cdot}N_2{\cdot}CH_2{\cdot}CO_2Et \xrightarrow{+HNO_2} Cl{\cdot}N_2{\cdot}CH(N{:}O){\cdot}CO_2Et \longrightarrow OH{\cdot}N{:}CCl{\cdot}CO_2Et$. A modifie dmethod is given for the preparation of ethyl and *n*-butyl diazoacetates. By the action of nitrous anhydride and of nitrosyl chloride on the ethyl diazoacetate a nitrile oxide, $C(\vdots N{:}O){\cdot}CO_2Et$, b. p. 132—133°/3 mm., d_4^{20} 1·2780, d_4^{25} 1·2726, was obtained which is unimolecular in benzene, bimolecular in ethylene dibromide, and intermediate in nitrobenzene; it has also been obtained from ethyl chloroaminoacetate and sodium carbonate. The decomposition of ethyl and *n*-butyl aminoacetates by nitrous acid in the presence of hydrochloric acid leads to the formation of the corresponding chloroacetates. Ethyl pyrazolinetricarboxylate, m. p. 98°, has been obtained by treating ethyl aminoacetate hydrochloride with nitrous acid in a manner described in the original and preserving the resulting liquid, b. p. 5—40°/4—5 mm., for several months. The preparation of *chloro-oximinoethane*, $CCl({:}N{\cdot}OH){\cdot}Me$, m. p. 84—85°, by the action of nitrous acid on ethylamine is described.

C. J. S.

Reactions of certain Aromatic and Aliphatic Derivatives. A. ANGELI (*Atti R. Accad. Lincei*, 1924, [v], **33**, 109—116).—The author quotes fresh data confirming his rule concerning the analogy of behaviour exhibited between two groups united directly and the same groups occupying ortho- or para-positions in one and the same aromatic nucleus (cf. A., 1923, i, 1003).

With reference to the mobility which the alkoxy groups of an aromatic nucleus impress on the halogen atoms of side chains in the ortho- or para-position to such groups, Werner and Goldschmiedt have shown that, whilst the group $CHPhCl$(or Br)· resists the action of boiling alcohol, the analogous ortho- or para-substituted groups, $OMe{\cdot}C_6H_4{\cdot}CHCl$(or Br)· and $CH_2O_2{:}C_6H_3{\cdot}CHCl{\cdot}$, are readily converted into $OMe{\cdot}C_6H_4{\cdot}CH(OEt){\cdot}$ and $CH_2O_2{:}C_6H_3{\cdot}CH(OEt){\cdot}$. Similarly, simple heating with alcohol produces the changes $OMe{\cdot}CH_2Cl \longrightarrow OMe{\cdot}CH_2{\cdot}OEt$(or Me). Such behaviour is limited to the halogen atom united to the carbon contiguous to the aromatic ring, halogens in other positions keeping their places; thus,

$$OMe{\cdot}C_6H_4{\cdot}CHBr{\cdot}CHBr{\cdot}CO_2H + Et{\cdot}OH \longrightarrow OMe{\cdot}C_6H_4{\cdot}CH(OEt){\cdot}CHBr{\cdot}CO_2H.$$

The same holds with aliphatic compounds containing a halogen atom at a distance from the carbon atom united to the alkoxyl; thus, the compounds $OMe{\cdot}CH_2{\cdot}CH_2Cl(I)$, $OEt{\cdot}CH_2{\cdot}CH_2I$, $OMe{\cdot}CH_2{\cdot}CBr(NO_2)_2$, and $O(CH_2{\cdot}CH_2I)_2$ are so stable that some of them resist the actions of sodium, zinc, sodium acetate, and silver acetate, whereas the compounds $O[CH_2Cl(or\ Br)]_2$ are so unstable that they decompose in moist air.

This varying behaviour of halogen atoms according to their position furnishes explanations for many reactions. The ready elimination of the halogen is regarded by Zincke and Werner as due to the formation of an intermediate oxonium or quinonic compound, thus, $OMe\cdot C_6H_4\cdot CHRBr \longrightarrow BrMe{-}O{:}C_6H_4{:}CHR$, or $OH\cdot C_6H_4\cdot CH_2Br \longrightarrow O{:}C_6H_4\cdot H(CH_2Br) \longrightarrow OH\cdot C_6H_4\cdot CH_2\cdot OEt$; an intermediate oxonium compound is probably formed in the case of the aliphatic derivatives: $OMe\cdot CH_2Br \longrightarrow BrMe{-}O{:}CH_2$. [Cf. Hoering, A., 1904, i, 577.]

Certain groups, such as the nitro and cyano residues, enhance the activity of other groups in the para-position in an aromatic nucleus. Thus, the nitrosoamine, $NPhMe\cdot NO$, exhibits indifferent behaviour and gives up the nitroso residue only with difficulty, whereas its *p*-nitro derivative, $NO_2\cdot C_6H_4\cdot NMe\cdot NO$, immediately yields diazomethane when treated with cold sodium hydroxide. Further, alkyl ethers of phenols yield their alkyl groups only as the result of energetic reactions, but if a nitroso- or an azo-group is introduced in the ortho position to the alkoxyl, the alkyl residue is easily removed with formation of the corresponding phenols: $Ph\cdot N_2\cdot C_6H_4\cdot OMe \longrightarrow Ph\cdot N_2\cdot C_6H_4\cdot OH$, and $NO\cdot C_6H_4\cdot OMe \longrightarrow NO\cdot C_6H_4\cdot OH$. Recently, Borsche and Exss (this vol., i, 218) have shown that the azo group increases the activity of halogen atoms in the ortho- or para-position, although its effect is less than that of other negative groups, such as the nitro, cyano, carbethoxy groups, etc.

In addition to the numerous examples, given earlier, of the migration of an oxygen atom from nitrogen to carbon, in aliphatic as well as in aromatic compounds, mention is made of the following, which take place under the influence of an alkali: the conversion of nitrocoumarone into an oxime, $C_6H_4<\begin{smallmatrix}CH\\O\end{smallmatrix}>C\cdot NO_2 \longrightarrow$ $C_6H_4<\begin{smallmatrix}CO\\O\end{smallmatrix}>C{:}NOH$, and the formation of an amide, $N_3\cdot C_6H_4\cdot CO\cdot NH_2$, from the *o*-azide, $N_3\cdot C_6H_4\cdot CH{:}NOH$; the latter change is the only example of such a transposition taking place in an alkaline medium.

T. H. P.

Low-temperature Tar obtained from the Zeche Fürst Hardenberg Coal and, in particular, the Content of Benzene, Phenol, and Acetone. Reply to Broche. F. Schütz, W. Buschmann, and H. Wissebach (*Ber.*, 1924, **57**, [*B*], 619—622; cf. A., 1923, i, 907).—The conflicting results obtained by Broche are due to the fact that the authors dealt with the composition of the so-called "tar benzines" (*i.e.*, the light oils obtained by dehydrating primary tar), whereas Broche mixed the "tar benzines" and the "gas benzines" together before examination. The authors confirm their previous results (cf. A., 1923, i, 195, 452) regarding the content of benzene, phenol, and acetone. H. Lange obtained 30 kg. of pure acetone on working up 120 cubic metres of tar-water; the authors do not accept Broche's suggestion that their "abnormal" results were due to overheating of the retorts. F. A. M.

Remarks on F. Fischer's Paper, "The Relation between Low-temperature Tar, Coke-oven Tar, and Petroleum." F. SCHÜTZ (*Ber.*, 1924, 57, [*B*], 623—627; cf. A., 1923, i, 889).—Facts are quoted, such as the percentage of aromatic hydrocarbons, specific gravities, etc., to prove that Fischer's view as to the similarity between crude petroleum and low-temperature tar cannot be maintained. On the contrary, the products obtained from the low-temperature carbonisation of coal must be regarded as new types of products which cannot be compared with the great majority of natural petroleums but are of great technical importance. [Cf. also preceding abstract.] F. A. M.

Japanese Petroleum. II. S. KOMATSU and N. TANAKA (*Mem. Coll. Sci. Kyōtō*, 1924, 7, 143—146; cf. this vol., i, 502).—Petroleum from Nishiyama, Echigo, contains benzene and *n*-hexane.

Hydrogenation of Aromatic Compounds with the Aid of Platinum. VII. Decahydronaphthalene prepared using Platinum Black. R. WILLSTÄTTER and F. SEITZ (*Ber.*, 1924, 57, [*B*], 683—684; cf. A., 1923, i, 771).—According to Hückel (this vol., i, 31), all preparations of decahydronaphthalene are mixtures of the *cis*- and *trans*-forms, the product obtained by the use of platinum black containing about 90% of the *cis*- and 10% of the *trans*-form. The authors have examined various preparations made with the aid of platinum and found all to have the constants (b. p. 193—193·5° corr.; d_4^{20} 0·8938—0·8942; n_D^{20} 1·4796) of the pure *cis*-form, nor could any trace of the *trans*-form be obtained on fractional distillation. Reduction of naphthalene with nickel and hydrogen at 160—162°, however, yielded chiefly the *trans*-form, d_4^{20} 0·8784; n_D^{20} 1·4729. F. A. M.

Preparation of Tetralin [Tetrahydronaphthalene]. H. INOUE (*J. Chem. Ind. Japan*, 1923, 26, 1316—1329).—For the hydrogenation of naphthalene, electrolytic hydrogen was used, and the nickel catalyst was prepared by electrolysing a 5—10% solution of sodium phthalate containing a slight excess of phthalic acid at 17—25°, using a nickel anode; the nickel hydroxide precipitated in the neighbourhood of the cathode is more active than that obtained by any other process. It is converted into oxide and then to metal at 310—320°. Purified naphthalene containing only 0·04% of sulphur was used and the hydrogenation was conducted in a specially designed autoclave of 7 litres capacity at 30 atm. pressure. The tetralin obtained had, after distillation, *d* 0·970. Decalin was prepared from tetralin by the same process. K. K.

Lely's Benzene Theory. J. D. VAN ROON (*Chem. Weekblad*, 1924, 21, 174).—A reply to Lely's response (this vol., i, 380) to the author's criticism of the theory. S. I. L.

Electrochemical Oxidation of Aromatic Hydrocarbons. F. FICHTER (*Trans. Amer. Electrochem. Soc.*, 1924, **45**, 75—95).—A general theoretical discussion of the electrolytic oxidation of benzene derivatives, illustrated mainly by the results of the author and his collaborators. Benzene is oxidised first to phenol, then to quinol and pyrocatechol, eventually to quinone, and is finally completely disrupted. The oxidation process is governed by the following factors: (1) concentration, (2) current density, (3) nature of anode, (4) influence of cathode if no diaphragm be used, (5) nature of the electrolyte, (6) secondary reactions, *i.e.* use of a solution of a salt of a metal having a variable valency, (7) superimposition of alternating on direct current.

When phenols are oxidised, the tendency is for *p*-quinones to be formed; thus anisole gives benzoquinone, *m*-tolyl methyl ether yields toluquinone, and *m*-xylenol *p*-xyloquinone. When phenol itself is appropriately oxidised there are formed, besides the usual products, certain hydroxydiphenyls and diphenyl ethers (Fichter and Brunner, A., 1916, i, 644; Fichter and Ackermann, A., 1919, i, 586). Recent investigation, the results of which remain unpublished, has shown that guaiacol, *p*-tolyl methyl ether, and *m*-xylenol similarly yield 4 : 4′-dihydroxy-3 : 3′-dimethoxydiphenyl, 2-hydroxy-2′-methoxy-4 : 4′-dimethyldiphenyl, and 2 : 2′-dihydroxy-3 : 5 : 3′ : 5′-tetramethyldiphenyl respectively. W. A. S.

Action of Sodium Sulphite on some Trinitro Compounds and on Tetranitromethane. Purification of Tolite [2 : 4 : 6-Trinitrotoluene]. H. MURAOUR (*Bull. Soc. chim.*, 1924, [iv], **35**, 367—379; cf. A., 1922, i, 443, 1006).—Dilute solutions of sodium sulphite (3 to 5%) dissolve 2 : 3 : 4-trinitrotoluene (β) and 2 : 4 : 5-trinitrotoluene (γ) in the cold, giving colourless solutions of the corresponding sodium dinitrosulphonates, one of the adjacent ortho-nitro groups being replaced. Thus 2 : 4 : 5-trinitrotoluene is converted into sodium 2 : 4-dinitrotoluene-5-sulphonate. Symmetrical trinitrotoluene, however, only reacts slightly with dilute sodium sulphite, forming an additive product which is only stable in concentrated solutions of the sulphite and from which, on dilution, the greater part of the trinitrotoluene is precipitated. Trinitrobenzene dissolves in cold dilute sodium sulphite giving an intense red solution, from which the trinitrobenzene is precipitated unchanged on acidifying. *s*-Trinitro-*m*-xylene and trinitromesitylene do not react with aqueous sodium sulphite. Tetranitromethane reacts readily; the reaction appears to proceed in two stages, the sodium trinitromethanesulphonate first formed being subsequently hydrolysed to the sodium salt of trinitromethane.

The purification of crude commercial trinitrotoluene by the sodium sulphite process is discussed, and the application of the process to the determination of the unsymmetrical trinitrotoluenes in crude trinitrotoluene is described.

The reaction has also been utilised for the separation and approximate determination of the trinitroxylenes, the trinitro-derivatives of *o*- and *p*-xylene reacting with dilute sodium sulphite, whilst trinitro-*m*-xylene does not. [Cf. *B.*, 1924, 451.] R. B.

Sulphonation of *p*-Cymene. M. PHILLIPS (*J. Amer. Chem. Soc.*, 1924, **46**, 686—694).—The proportions of the isomeric monosulphonic acids produced by sulphonation of *p*-cymene have been investigated using a method based on the melting-point curves of the corresponding sulphonamides. The proportion of sulphuric acid used has less effect than temperature. The best yield of the β-acid (*p*-cymene-3-sulphonic acid) is obtained using 1 part of *p*-cymene to 3 parts of sulphuric acid, sulphonating for 4 hours at 100°. Sulphonation at lower temperatures favours formation of the 2-isomeride; thus 15·6% of the 3-sulphonic acid is formed at 100° and 2·5% at 0° (using fuming sulphuric acid containing 20% of anhydride). No disulphonic acid appears to be formed at or below 50°, but increasing amounts are produced at higher temperatures. The proportion of *p*-cymene-2-sulphonic acid is somewhat increased by addition of copper or mercuric sulphate.

C. J. S.

Synthesis of Higher Homologues of *m*-Methylethylbenzene. A. MAILHE (*Bull. Soc. chim.*, 1924, [iv], **35**, 365—367).—By the action of acid chlorides on *m*-methylethylbenzene in carbon disulphide solution in the presence of aluminium chloride, followed by hydrogenation of the ketone first formed in the presence of nickel according to Darzens' method (A., 1905, i, 66), a number of higher homologues of *m*-methylethylbenzene have been obtained. The new alkyl group enters the benzene ring in the 6-position. 2-*Methyl-4-ethylacetophenone* has b. p. 239—240° (*semicarbazone*, m. p. 185°), 1-*methyl-3* : 6-*diethylbenzene*, b. p. 205—207°; 2-*methyl-4-ethylphenyl ethyl ketone*, b. p. 250—252°; 1-*methyl-3-ethyl-6-propylbenzene*, b. p. 213—215°, d_4^{11} 0·8831; 2-*methyl-4-ethylphenyl* iso*propyl ketone*, m. p. 132°, b. p. 258—259°, d_4^{11} 0·9557; 1-*methyl-3-ethyl-6-*iso*butylbenzene*, b. p. 228—229°, d_4^{11} 0·8863; 2-*methyl-4-ethylphenyl propyl ketone*, b. p. 265—266°; 1-*methyl-3-ethyl-6-butylbenzene*, b. p. 236—237°, d^{11} 0·6882(?); 2-*methyl-4-ethylphenyl* iso*butyl ketone*, b. p. 274°; 1-*methyl-3-ethyl-6-*iso*amylbenzene*, b. p. 245—246°, d^{11} 0·8801. By the action of benzoyl chloride on *m*-methylethylbenzene in the presence of aluminium chloride 2-*methyl-4-ethylbenzophenone*, b. p. 318—320°, was obtained, which on hydrogenation was converted into 2-*methyl-4-ethyldiphenylmethane*, b. p. 298—300°, d^{11} 1·0141. R. B.

Alkylation of Primary Amines with Aluminium Alkoxides to give Secondary Amines Free from Tertiary Amines. W. A. LAZIER and H. ADKINS (*J. Amer. Chem. Soc.*, 1924, **46**, 741—746).—Both aromatic and aliphatic primary amines may be alkylated by heating with aluminium alkoxide in sealed tubes at 250—350°. Aniline with aluminium ethoxide yielded a colourless reaction product containing 94% of ethylaniline and 6% of aniline. Other secondary amines were prepared in good yield by alkylating aniline, *p*-toluidine, and *n*-amylamine, but the optimum conditions have not yet been ascertained. The yields obtained, using acetanilide in place of aniline, were considerably lower. These results do not support Nef's dissociation hypothesis (A., 1901, i, 626), by which he explained the mechanism of alkylation.

C. J. S.

Highly Chlorinated Hydroaromatic Products containing Nitrogen. DURAND und HUGUENIN A.-G. (Brit. Pat. 198676).—Amines containing negative substituents are chlorinated, in the absence of moisture, without previously protecting the amino group by salt formation, as is necessary in the case of the unsubstituted amines (cf. Brit. Pat. 193843). For example, chlorine is introduced into an ice-cooled solution of 20 g. of 2 : 5-dichloroaniline in 600 c.c. of chlorobenzene. The paste initially formed having become fluid, the mixture is heated at about 100°, filtered, and the chlorobenzene distilled under diminished pressure. A crystalline compound (containing eight chlorine atoms) separates, which crystallises from light petroleum in colourless laminæ, m. p. 125°.

W. T. K. B.

Nitration of *p*-Bromoacetanilide. R. H. GRIFFITH (*J. Chem. Soc.*, 1924, **125**, 940—941).—The nitration of *p*-bromoacetanilide at 10° with excess of nitric acid and sulphuric acid yields 2 : 4-dibromo-6-nitroacetanilide, m. p. 215°, 4-bromo-2 : 6-dinitroacetanilide, and 4-bromo-2-nitroacetanilide. 2 : 4-Dibromoacetanilide nitrated with excess of fuming nitric acid yields 2 : 4-dibromo-6-nitroacetanilide, which is hydrolysed to 2 : 4-dibromo-6-nitroaniline, m. p. 128°, with alcoholic hydrochloric acid. Nitration in the presence of sulphuric acid yields 2 : 4-dibromo-5-nitroacetanilide, m. p. 172°. 4-Bromo-2 : 6-dinitroaniline melts at 162°.

R. B.

Electrolytic Preparation of Metanilic Acid and its Commercial Possibilities. A. K. DOOLITTLE (*Trans. Amer. Electrochem. Soc.*, 1924, 45, 43—62).—In only one particular is the electrolytic reduction of *m*-nitrobenzenesulphonic acid likely to be more advantageous than the usual iron reduction, and that is that the former process might be made continuous. The author has therefore investigated the electrolytic method, using lead electrodes and 10% sulphuric acid as electrolyte. To the cathode solution, contained in a porous vessel, pure calcium *m*-nitrobenzenesulphonate was added. Reduction did not take place at 24°. The best results were obtained at 70°, with a bright lead cathode, current density 0·585 amp. per sq. dm., and cathode solution 1%. The yield was 67% of theory and current efficiency 64%. [Cf. *B.*, 1924, 288.]

W. A. S.

Crystallographic Investigation of *p*-ββ-Dimethylpropylbenzenesulphanilide and Benzyltrimethylsilicane-*p*-sulphanilide. N. ZENZÉN (*Arkiv Kem., Min., Geol.*, 1923, **8**, No. 34, 1—10).—*p*-ββ-Dimethylpropylbenzenesulphanilide,

$$CMe_3\cdot CH_2\cdot C_6H_4\cdot SO_2\cdot NHPh$$

(cf. Bygdén, A., 1920, i, 478), crystallises in holohedral monoclinic crystals, $a:b:c=0\cdot6869:1:0\cdot7536$, $\beta=113°\ 17'$, and benzyltrimethylsilicane-*p*-sulphanilide, $SiMe_3\cdot CH_2\cdot C_6H_4\cdot SO_2\cdot NHPh$ (cf. Bygdén, A., 1918, i, 134), also in holohedral monoclinic crystals, $a:b:c=0\cdot6973:1:0\cdot7698$, $\beta=113°\ 38'$. True mixed crystals of these two compounds are formed. The axial angle usually has appreciably different values at the two sides of a mixed crystal, probably on account of its zonal structure. T. H. P.

Decomposition of Quaternary Ammonium Hydroxides. J. v. Braun and R. S. Cahn (*Annalen*, 1924, **436**, 262—273; cf. A., 1911, i, 610).—The decomposition of β-phenylethyltrimethylammonium hydroxide giving a quantitative yield of styrene and a tertiary base has been applied to the synthesis of tertiary bases previously difficult to obtain. By the action of β-phenylethylamine on ethyl αα′-dibromoadipate in chloroform solution are obtained *ethyl* β-*phenylethylpyrrolidine*-2 : 5-*dicarboxylate*, oil, b. p. 212—214°/14 mm. (*chloroplatinate*, decomp. 160—161°), and ethyl αα′-di(β-phenylethylamino)adipate,

$$[CO_2Et\cdot CH(NH\cdot CH_2\cdot CH_2Ph)CH_2\cdot]_2,$$

a thick oil; the free acid, $C_{22}H_{28}O_4N_2$, forms long, colourless needles, m. p. 118°. 1-β-*Phenylethylpyrrolidine*-2 : 5-*dicarboxylic acid*, colourless crystals, decomp. 215° (*hydrochloride*, m. p. 177—178°), on dry distillation gives 1-β-phenylethylpyrrolidine, a mobile oil, b. p. 138—139°/21 mm. (*picrate*, m. p. 139—140°, *methiodide*, m. p. 143°). The methiodide on treatment with silver oxide and distillation of the quaternary ammonium hydroxide gives 60% of the theoretical yield of styrene and 1-methylpyrrolidine, b. p. 78°. Reduction of ethyl 1-β-phenylethylpyrrolidine-2 : 5-dicarboxylate with sodium and alcohol yields 1-β-*phenylethyl*-2 : 5-*dihydroxymethylpyrrolidine*, a viscous, colourless oil, b. p. 225°/13 mm. (*hydrochloride*, m. p. 127—129°, *picrate*, m. p. 108—111°, *methiodide*, oily), but the yield is small and no attempt was made to convert it into the corresponding 1-methylpyrrolidine.

β-Phenylethyldimethylamine reacts readily with *o*-xylylene bromide (for the preparation of which a new method from *o*-toluidine is described), in chloroform solution, yielding the *diquaternary bromide*, $C_{28}H_{38}N_2Br_2$, colourless crystals, m. p. 206°, which on treatment with silver oxide and distillation gives 65% of the theoretical yield of styrene and 60% of tetramethyl-*o*-xylylenediamine, $C_6H_4(CH_2\cdot NMe_2)_2$, colourless oil, b. p. 105—106°/14 mm. [*picrate*, m. p. 187—188°, *methiodide*, m. p. 219° (decomp.)].

β-Phenylethyldimethylamine and αε-dibromopentane react readily at water-bath temperature, giving the *diquaternary bromide*, $CH_2(CH_2\cdot CH_2\cdot NMe_2Br\cdot CH_2\cdot CH_2Ph)_2$, m. p. 121°, which on conversion into the hydroxide and distillation gives 60% of the theoretical yield of styrene and 25% of tetramethylpentamethylenediamine.

R. B.

Tenacity of Organic Residues. II. J. v. Braun and H. Engel (*Annalen*, 1924, **436**, 299—320; cf. A., 1923, i, 1193).—Further experiments have been undertaken to test the relative firmness of attachment of groups of the benzyl and allyl type to nitrogen and to halogen. By decomposition of appropriate tertiary bases with cyanogen bromide, it is shown that the introduction of the groups Me, Et, Ph, respectively, into the para-position in the benzyl radical diminishes in the order named the firmness with which the substituted benzyl group is attached to nitrogen. A similar result was obtained from experiments in the allyl series with the radicals allyl, crotonyl, and cinnamyl. The affinity of the radicals for nitrogen (and also for carbon) accordingly stands in the order $Me < Et < Ph$, and the same order holds in regard to chlorine. These results are at variance with those of Meerwein (A., 1920, i, 2) and Skraup (A., 1919, i, 598; 1922, i, 574), but the order $Ph < p\text{-}C_6H_4Me\cdot < p\text{-}C_6H_4Et\cdot < p\text{-}C_6H_4Ph\cdot$ is in accordance with Skraup's observations and those of Schlenk on the dissociation of hexa-arylethanes. A comparison of the allyl and benzyl series shows that in regard to nitrogen the radicals can be arranged in the following order of diminishing affinity: $CH_2Ph–$, $CH_2{:}CH\cdot CH_2–$, $CHMe{:}CH\cdot CH_2–$, $CHPh{:}CH\cdot CH_2–$, $p\text{-}C_6H_4Me\cdot CH_2–$, $p\text{-}C_6H_4Et\cdot CH_2–$, $p\text{-}C_6H_4Ph\cdot CH_2–$, methylation of the benzyl residue in the para-position decreasing the firmness of its attachment to nitrogen more than phenylation of the allyl residue. Similar results were obtained by studying the reaction of benzyl, *p*-methylbenzyl, *p*-ethylbenzyl, and *p*-phenylbenzyl chlorides with sodium ethoxide.

p-*Ethylbenzyl alcohol*, b. p. 115—117°/9 mm., was obtained by the action of potassium hydroxide on the corresponding aldehyde, prepared by Gattermann's method (A., 1897, i, 519), and with hydrochloric acid was converted into p-*ethylbenzyl chloride*, b. p. 81—82°/11 mm. p-*Phenylbenzyl chloride*, m. p. 68°, is similarly prepared through p-*phenylbenzyl alcohol*, m. p. 101—102°, b. p. 183—184°/11 mm., from *p*-phenylbenzaldehyde (obtained from diphenyl by Gattermann's method), or alternatively from *p*-phenylbenzonitrile by catalytic reduction to p-*phenylbenzylamine*, colourless crystals, m. p. 127—128° (*hydrochloride*, sparingly soluble, m. p. 282°; *picrate*, m. p. 205°; *acetyl* derivative, m. p. 180°; *benzoyl* derivative, m. p. 162°; *phenylthiocarbamide*, m. p. 150°; *methiodide*, m. p. 221°), and conversion of the amide into the alcohol by the diazo reaction. The secondary base, *di*-p-*phenylbenzylamine*, m. p. 132° (*hydrochloride*, m. p. above 300°, *nitroso* compound, m. p. 170°), is also formed in the reduction.

Benzylmethylamine (obtained by catalytic reduction of benzylidenemethylamine with nickel at 100°) with *p*-methylbenzyl chloride yields *benzyl*-p-*methylbenzylmethylamine*, colourless liquid, b. p. 160°/11 mm. (*methiodide*, m. p. 190°), which is converted by cyanogen bromide into a quaternary *salt*, probably *benzyldi*-p-*methylbenzylmethylammonium bromide*, m. p. 184°, p-*methylbenzyltrimethylammonium bromide*, m. p. 170—175°, and benzylmethylcyanamide, b. p. 139—140°/12 mm. In a similar manner *benzyl*-p-*phenylbenzylmethylamine*, m. p. 44°, b. p. 190—192° (*hydrochloride*, m. p. 187°; *picrate*, m. p. 146°; *methiodide*, m. p. 162°), is obtained and transformed by cyanogen bromide into an oily quaternary salt, *p*-phenylbenzyltrimethylammonium bromide, m. p. 200°, and benzylmethylcyanamide.

p-*Methylbenzylmethylamine*, b. p. 83°/11 mm. (*hydrochloride*, m. p. 174°; *picrate*, m. p. 145°), was obtained by reduction of the Schiff's base from *p*-tolualdehyde and methylamine with sodium and alcohol. With *p*-ethylbenzyl chloride this yields the tertiary base, p-*methylbenzyl*-p-*ethylbenzylmethylamine*, b. p. 181°/9 mm., which on treatment with cyanogen bromide yields the quaternary salt, $C_6H_4Me\cdot CH_2\cdot NMe(CH_2\cdot C_6H_4Et)_2Br$, m. p. 168°; *p*-ethylbenzyltrimethylammonium bromide (chloroplatinate, m. p. 216°), and *p*-methylbenzylmethylcyanamide. p-*Methylbenzyl*-p-*phenylbenzylmethylamine*, b. p. 253—255°/13 mm., was similarly obtained from *p*-phenylbenzyl chloride, and this base by treatment with cyanogen bromide yields an oily quaternary salt, *p*-phenylbenzyltrimethylammonium bromide, m. p. 200°, and a substance, m. p. 70°, containing bromine, probably formed by the action of cyanogen bromide on the primarily formed *p*-methylbenzylmethylcyanamide. In a similar way p-*methylbenzylmethylbutenylamine*,

$$C_6H_4Me\cdot CH_2\cdot NMe\cdot CH_2\cdot CH{:}CHMe,$$

b. p. 116—118°/11 mm., is obtained by the action of crotonyl bromide on p-*methylbenzylmethylamine*, and this base is transformed by cyanogen bromide into an oily quaternary compound, *p*-methylbenzyltrimethylammonium bromide (m. p. 184°), and *methylcrotonylcyanamide*, $CHMe{:}CH\cdot CH_2\cdot NMe\cdot CN$, b. p. 92—93°/55 mm.

p-*Methylbenzylcinnamylmethylamine*, b. p. 218—220°/12 mm., is decomposed by cyanogen bromide with production of an oily quaternary salt, *p*-methylbenzyltrimethylammonium bromide (m. p. 194°), and cinnamylmethylcyanamide.

p-*Ethylbenzylmethylamine*, b. p. 105°/10 mm., obtained by the action of *p*-ethylbenzyl chloride on methylamine, reacts with *p*-phenylbenzyl chloride, yielding p-*phenylbenzyl*-p-*ethylbenzylmethylamine*, b. p. 255—257°/11 mm. (*hydrochloride*, m. p. 205°), which on decomposition with cyanogen bromide gives an oily quaternary salt, *p*-phenylbenzyltrimethylammonium bromide, and *p*-ethylbenzylmethylcyanamide.

p-*Phenylbenzylmethylamine*, b. p. 173—174°/11 mm., was obtained by condensing *p*-phenylbenzaldehyde with methylamine and reducing the Schiff's base (m. p. 51°) with sodium. With cinnamyl bromide, it yields an oily quaternary compound which on distillation in a vacuum yields a tertiary *base*, $C_{23}H_{23}N$ (*hydrochloride*, m. p. 224°), which is converted by cyanogen bromide into an oily quaternary salt, *p*-phenylbenzyltrimethylammonium bromide (m. p. 198°), and cinnamylmethylcyanamide.

Cinnamylmethylamine is a mobile liquid, b. p. 110—112°/12 mm. With allyl bromide it yields *cinnamylmethylallylamine*, $CHPh{:}CH\cdot CH_2\cdot NMe\cdot CH_2\cdot CH{:}CH_2$, b. p. 166—168°/11 mm., which on decomposition with cyanogen bromide yields an oily quaternary compound (*chloroplatinate*, $C_{44}H_{52}N_2\cdot Cl_6Pt$, m. p. 85°), cinnamyltrimethylammonium bromide (m. p. 165°), and *methylallylcyanamide*, $CH_2{:}CH\cdot CH_2\cdot NMe\cdot CN$. Similarly from cinnamylmethylamine and crotonyl chloride is obtained *cinnamylmethylcrotonylamine*, b. p. 180—182°/10 mm., from which the quaternary salt, $(CHPh{:}CH\cdot CH_2)_2NMe(CH_2\cdot CH{:}CHMe)Br$, m. p. 79°, cinnamyl bromide, and methylcrotonylcyanamide are formed on treatment with cyanogen bromide. R. B.

Catalytic Reduction of Phenol and α-Naphthol under High Pressure. H. Inoue (*J. Chem. Ind. Japan*, 1923, **26**, 1330—1334; cf. this vol., p. 628).—By the same method as that used in the catalytic preparation of tetralin, phenol was reduced at about 200° to *cyclo*hexanol (b. p. 135°, d^{20} 0·9547, n_D^{20} 1·4650), and α-naphthol to a mixture of tetralin (46·6%), *ar*-tetrahydro-α-naphthol (40·9%), and α-ketotetrahydronaphthalene (12·5%). K. K.

Esterification of *cyclo*Hexanol and some of its Homologues. (Mlle.) G. Cauquil (*Compt. rend.*, 1924, **178**, 1538—1540; cf. this vol., i, 280).—On heating 2-, 3-, and 4-methyl*cyclo*hexanol with acetic acid, 49·8%, 53·1%, and 54·1%, respectively, of the three alcohols has undergone esterification at equilibrium, showing a decrease of 5·8, 2·5, and 1·5%, compared with *cyclo*hexanol. For 3 : 4-dimethyl*cyclo*hexanol the corresponding decrease is 8·1 and for 2-ethyl*cyclo*hexanol, 6·4%. J. W. B.

Preparation of Stereoisomerides in the Disubstituted *cyclo*Hexanol Series. M. Godchot and P. Bedos (*Compt. rend.*, 1924, **178**, 1184—1186).—The action of hypochlorous acid on Δ^3-methyl*cyclo*hexene results in the formation of a mixture of two isomerides of *4-chloro-1-methyl*cyclo*hexan-3-ol.* These were separated by repeated fractionations, and the two fractions were converted by the Grignard reaction into two *1 : 4-dimethyl*cyclo*hexan-2-ols*, yielding *allophanates* of m. p. 158° and 125°, respectively. The alcohols on regeneration from these esters were colourless liquids, b. p. 175°/760 mm., d^{17} 0·9066, n_D^{17} 1·4521, and b. p. 177°/760 mm., d^{17} 0·9079, n_D^{17} 1·4544, respectively. On oxidation with chromic acid, both alcohols give *1 : 4-dimethyl*cyclo*hexan-2-one*, b. p. 171—172°; *semicarbazone*, m. p. 122°. H. J. E.

Auto-oxidation and Anti-oxygens. Catalytic Properties of Iodophenols. C. Moureu, C. Dufraisse, and J. P. des Touches (*Compt. rend.*, 1924, **178**, 1497—1501; cf. A., 1922, i, 250; 1923, ii, 308).—The inhibiting action on the auto-oxidation of acraldehyde of substances containing both a phenolic group and iodine in the same molecule has been studied. Within the limits of experimental error, neither exaltation nor diminution in the activity of the phenol group occurs. Thus *o*-iodophenol exhibits a very slight diminution in activity compared with phenol itself. The very slight activity of iodobenzene shows that iodine in the nucleus has very little effect; but the introduction of a second phenolic group in the *o*-position (pyrocatechol) increases the activity coefficient 200 times. The activities of 2 : 6- and 3 : 4-di-iodophenol, and 2 : 4 : 6-tri-iodophenol are only slightly greater than that of phenol itself, and in equal molecular concentration 2 : 6-di-iodoquinol has the same activity as quinol. The dimethyl ether of monoiodoquinol has the same activity as quinol dimethyl ether, each exhibiting an initial retarding effect followed by a distinct acceleration of the auto-oxidation. J. W. B.

Nitration. II. Mononitration of Phenol. F. Arnall (*J. Chem. Soc.*, 1924, **125**, 811—816; cf. *ibid.*, 1923, **123**, 3111).—Nitration of phenol in an organic solvent gives much better results than in aqueous solution, but the velocity of nitration depends on the nature of the solvent. At 10°, reaction in acetic anhydride containing 10% of nitric acid is apparently instantaneous. In acetone, nitration with 10% nitric acid proceeds to the extent of 80% in 3 hours; in ether, 68% in 12 hours; in alcohol (2 parts) and acetic acid (1 part), 75% in 48 hours; in absolute alcohol, 55% in 48 hours. The relative proportions of the isomerides are independent of the solvent. The best results were obtained with glacial acetic acid, without formation of tar, the yield being almost quantitative at temperatures up to 50°. Raising the temperature of nitration or increasing the concentration of the nitric acid slightly increases the proportion of *o*-nitrophenol formed. The best yields of the mononitrophenols were obtained with 10% nitric acid at 25°. The mixture of mononitrophenols was analysed by a method involving steam distillation of the *o*-nitrophenol and thermal analysis of the benzyl ethers of *m*- and *p*-nitrophenol.

The following derivatives of *m*-nitrophenol have been obtained: *acetate*, m. p. 55—56°; *picrate*, m. p. 170—171°; *benzyl ether*, m. p. 55°; *acetonyl ether*, m. p. 83—84°; acetophenonyl ether, m. p. 127°. R. B.

Action of Bromine on Methyl Esters of Phenolsulphonic Acids. Determination of Sulphur in Phenolsulphonic Esters and Salts. L. J. Simon and M. Frêrejacque (*Compt. rend.*, 1924, **178**, 1282—1284).—The action at a low temperature of bromine (1 atom) on methyl *o*-cresolsulphonate in methyl-alcoholic solution, yields (1) the *methyl bromo-o-cresolsulphonate*, m. p. 143°, which retains the methylating properties of the original compound and gives, in particular, the characteristic derivative of hexamethylenetetramine (cf. this vol., i, 665), and (2) the corresponding bromo-*o*-cresolsulphonic acid. At 100° a second bromine atom enters the nucleus, from which it displaces the sulphonic group, so that, if excess of bromine is employed, the sole products of the reaction are dibromo-*o*-cresol and sulphuric acid. Similar products are obtained from methyl anisole-*p*-sulphonate, which also takes up a second bromine atom only by elimination of the sulphonic group.

Methyl sulphate, which sulphonates the phenols so readily, has no action on their bromo derivatives, even at higher temperatures (cf. A., 1923, i, 462, 1098). This inertness is in harmony with the total elimination of the sulphonic group by bromine, which allows of the use of the latter for the determination of the sulphur in sulphonic derivatives of phenols. Desvergnes' method (A., 1920, ii, 563) gives satisfactory results with the methyl esters of various phenolsulphonic acids, and with the water-soluble additive products of the sulphonic esters with tertiary bases. No sulphuric acid is, however, liberated from the acyclic methanesulphonic and sulphoacetic acids. [Cf. *B.*, 1924, 444.] T. H. P.

Ultra-violet Absorption Spectra of Eugenol. G. THOMPSON (*J. Chem. Soc.*, 1924, **125**, 962; cf. *ibid.*, 1923, **123**, 1594).—The absorption spectrum of eugenol in thin films agrees closely with its spectrum in alcoholic solution, and the absorption bands previously recorded are therefore characteristic of the substance itself. Extinction coefficients could not be calculated, as it was not possible to measure the thickness of the films. R. B.

Catalytic Action. V. Catalytic Reduction of α- and β-Naphthyl Methyl Ethers. S. KOMATSU and S. KUMAMOTO (*Mem. Coll. Sci. Kyōtō*, 1924, 7, 135—142).—The catalytic reduction of α-naphthol has previously been found to yield products containing *ar*- and *ac*-compounds in the ratio 1 : 9 (A., 1923, i, 782), whereas the presence of the amino group in α-naphthylamine favours the formation of *ar*-derivatives, the ratio of *ar*- to *ac*-compounds being 9 : 1. When α-naphthyl methyl ether is reduced by means of hydrogen and reduced nickel at 200°, the molecular ratio of *ar*- to *ac*-compounds is 19 : 81. β-Naphthyl methyl ether forms *ac*-derivatives less readily than does the α-ether, the molecular ratio of *ar*- to *ac*-products being 37 : 63. When reduced with sodium and boiling amyl alcohol, α- and β-naphthyl methyl ethers yield only *ar*-tetrahydronaphthyl ethers, but when β-naphthyl methyl ether is reduced with sodium and ethyl alcohol, β-*ar*-dihydronaphthyl methyl ether is obtained. C. J. S.

Preparation of 2- and 4-Nitro-α-naphthols. H. H. HODGSON and E. KILNER (*J. Chem. Soc.*, 1924, **125**, 807—811).—The 2- and 4-nitro compounds obtained by the nitration of aceto-α-naphthalide (cf. A., 1886, 754; T., 1905, **87**, 928) can be easily separated by hydrolysing the mixture with boiling 5% sodium hydroxide, and distilling the acidified solution with steam, whereby 2-nitro-α-naphthol is removed. The mixture was thus found to contain the 2- and 4-nitroaceto-α-naphthalides in the proportion 1 : 3. The poor yields of 2-nitro-α-naphthol obtained in the oxidation of 2-nitroso-1-naphthol with dilute nitric acid (A., 1892, 861) are due to the action of nitrous acid, liberated during the reaction, on the nitronaphthol. 4-Nitro-α-naphthol is attacked more rapidly than the 2-nitro compound. The addition of carbamide to the oxidation mixture raises the yield of 2-nitro-α-naphthol to 50% of the theoretical. Better results were obtained by using 100 vol. hydrogen peroxide, the yield being 50—60%. The by-products are soluble derivatives of phthalic acid. Ammonium 2-nitro-α-naphthoxide, in contrast with the nitronaphthol itself, can be distilled in steam without resinification. R. B.

Manufacture of G-Acid [β-Naphthol-6 : 8-disulphonic Acid], using Fuming Sulphuric Acid. T. KAWAGUCHI (*J. Chem. Ind. Japan*, 1923, **26**, 1233—1256).—When 1 part of β-naphthol is sulphonated with 5 parts of fuming sulphuric acid containing

20% of sulphur trioxide at 20—25° during 8 hours, G acid is the principal product, with β-naphthol-3 : 6-disulphonic acid (R acid) and -6-sulphonic acid (Schäffer acid) as by-products. Separating the last by partial crystallisation as barium salt, and G and R acids through the difference in solubility of their sodium salts in aqueous alcoholic solution, 2 grams of barium salt of Schäffer acid, 61 grams of sodium salt of G acid, and 22 grams of sodium salt of R acid were isolated from 50 grams of β-naphthol. Neglecting Schäffer acid, if G and R acids are separated as acid potassium and sodium salts, the yields of the two salts are 75 grams and 17 grams, respectively, from the same amount of β-naphthol.

K. K.

So-called Auxochromes and their Method of Action. A. Hantzsch (*Annalen*, 1924, **436**, 321—323).—A defence of the author's theory of isomeric change, in reply to Kaufmann (A., 1924, i, 37).

R. B.

Reaction of Resorcinol and of Phloroglucinol with Formaldehyde. A. Zamparo (*Boll. Chim. Farm.*, 1924, **63**, 161—164).—Resorcinol and phloroglucinol are the only ordinary phenolic compounds which react immediately in the cold to give coloured precipitates when 0·1 g. is dissolved in 3 c.c. of 95% alcohol and the solution is treated successively with 2 c.c. of 40% formaldehyde solution and 3 c.c. of concentrated hydrochloric acid; the two naphthols and thymol give precipitates soluble in alcohol. [Cf. *B.*, 1924, 445.]

T. H. P.

Dyes of the Aurin Type. II. H. Baines and J. E. Driver (*J. Chem. Soc.*, 1924, **125**, 907—910; cf. *ibid.*, 1923, **123**, 1214).—By the action of chloroform vapour on dry potassium phenoxide at 110° in the absence of oxygen, triphenyl orthoformate, m. p. 75°, and leucaurin, $CH(C_6H_4OH)_3$, are produced. The reaction proceeds more slowly with boiling chloroform, but the yield is greatly diminished by the presence of water and is not appreciably increased by using alcohol as solvent.

R. B.

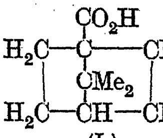
Catalytic Preparation of Benzyl Ethers. J. B. Senderens (*Compt. rend.*, 1924, **178**, 1412—1415).—The method previously described (this vol., i, 40) has now been applied to the preparation of benzyl ether, and of the mixed benzyl ethyl, benzyl propyl, benzyl *iso*propyl, benzyl butyl, benzyl *iso*butyl, and benzyl *iso*amyl ethers. For these mixed ethers, the boiling point rises, but the density diminishes as the molecular weight increases.

T. H. P.

Chemical Nature of the Naphthenic Acids. O. Aschan (*Ber.*, 1924, **57**, [*B*], 636—637).—A reply to a paper by Zelinsky and Pokrowskaja (this vol., i, 387) criticising work done by the author in 1892 (A., 1893, i, 209). The heptanaphthenecarboxylic acid was obtained pure by redistilling the methyl ester 30 times and boiled within 2°; it was probably purer than that obtained by Zelinsky and Pokrowskaja. The author had suggested in 1892

fore not novel. F. A. M.

Ketopinic Acid. Conversion into Norcamphane-1-carboxylic Acid. E. Wedekind [with C. Weinand] (*Ber.*, 1924, 57, [*B*], 664—666).—Ketopinic acid (cf. Wedekind, Schenk, and Stüsser, A., 1923, i, 346) is converted into its *semicarbazone*, m. p. 226°, which is transformed by sodium ethoxide and ethyl alcohol at 170—180° into *norcamphane*-1-*carboxylic acid* (I), m. p. 221—222°; the *copper, lead, mercury, silver,* and *zinc* salts are described. The *calcium* salt is particularly characteristic.



(I.)

The *phenylhydrazide*, m. p. 140°, and the *amide*, m. p. 192·5°, of ketopinic acid are described. The acid is associated to a considerable degree in benzene even in dilute solution. H. W.

Catalytic Action. VI. Catalytic Action of Reduced Copper on Acid Amides. S. Komatsu and M. Kurata (*Mem. Coll. Sci. Kyōtō*, 1924, 7, 157—159).—The suggestion that at a high temperature reduced copper causes simultaneous dehydration and hydration has been confirmed by passing menthon*iso*oxime over the catalyst at 200°, whereby menthonitrile and decenoic acid were obtained. Benzamide when passed over reduced copper at 250° gives benzonitrile and benzoic acid, whilst acetamide (at 200°) yields acetonitrile and acetic acid. C. J. S.

Condensation of Nitriles with Thioamides. II. Acetonitrile with Thiobenzamide, and Benzonitrile with Thioacetamide. S. Ishikawa (*Mem. Coll. Sci. Kyōtō*, 1924, 7, 93—98; cf. A., 1921, i, 728).—The combination of acetonitrile and thiobenzamide, induced by saturating their ethereal solution with dry hydrogen chloride, yields, not acetimino*iso*benzamide, but benzimino*iso*thiobenzamide. The fact that thioacetamide is found in the resulting solution indicates that the acetonitrile and thiobenzamide first condense similarly to benzonitrile and thiobenzamide, and that the condensation product is unstable and decomposes into benzonitrile and thioacetamide: $CH_3{\cdot}CN + NH{:}CPh{\cdot}SH \longrightarrow NH{:}CMe{\cdot}N{:}CPh{\cdot}SH \longrightarrow NH{:}CMe{\cdot}SH + C_6H_5{\cdot}CN$; equilibrium is reached when about 20% of the reacting compounds is converted into the final products. From benzonitrile and thioacetamide, benzimino*iso*thiobenzamide and thiobenzamide were obtained, the latter product representing about 71% of the benzonitrile.

Electrolytic Oxidation of *p*-Nitrotoluene and *p*-Chlorotoluene to their respective Acids. R. Dunbrook and A. Lowy (*Trans. Amer. Electrochem. Soc.*, 1924, 45, 97—117).—Using 20% nitric acid as the electrolyte and platinum electrodes, *p*-nitrotoluene and *p*-chlorotoluene were oxidised to *p*-nitrobenzoic and *p*-chlorobenzoic acids, respectively. In the first case, the best conditions were with a current density of 4 amp. per sq. dm., at 100°, a current efficiency of 34·1% being obtained. In the second case, the current density was 0·5 amp. per sq. dm. and the current efficiency was 65%, but with acetic acid as solvent it rose to 96%. [Cf. *B.*, 1924, 444.] W. A. S.

[*p*-Aminobenzoic] Esters of Substituted Aminopropyl Alcohol. W. Schulemann, L. Schütz, and K. Meisenburg (U. S. Pat. 1474567).—dl-γ-*Dimethylamino*-αβ-*dimethylpropyl* p-*aminobenzoate* (crystalline *hydrochloride*) has m. p. 81—82°. dl-γ-*Diethylamino*-αβ-*diethylpropyl* p-*aminobenzoate hydrochloride* has m. p. 146°. γ-*Diethylamino*-β-*methyl*-α-*ethylpropyl* p-*aminobenzoate hydrochloride* has m. p. 178°. Chemical Abstracts.

Synthetic Anæsthetics [Alkylaminoalkyl *p*-Aminobenzoates. E. H. Volwiler and R. Adams (U.S. Pat. 1476934).—γ-*Butylallylaminopropyl* p-*aminobenzoate hydrochloride* forms white needles, m. p. 147°. *Butylallylamine*, from butyl bromide and allylamine, has b. p. 132—133°/760 mm. β-*Butylallylaminoethyl* p-*aminobenzoate hydrochloride* has m. p. 184°. The *hydrochlorides* of *propylallylaminopropyl* and iso*propylallylaminopropyl* p-*aminobenzoates* are viscous oils. iso*Amylallylaminoethyl alcohol*, b. p. 132—133°/55 mm. (obtained by heating ethylene oxide with *iso*amylallylamine at 60°) yields a p-*aminobenzoate hydrochloride*, m. p. 194—195°. Chemical Abstracts.

Identity of Abietic Acids Extracted from Different Colophonies. G. Dupont and R. Uzac (*Bull. Soc. chim.*, 1924, [iv], 35, 394—404; cf. Schulz, *Mon. Sci.*, 1920, **10**, 109).—Crude abietic acid, obtained by extracting colophony with 95% alcohol and hydrochloric acid, was purified by crystallisation to a constant rotatory power. In this way, pure abietic acid of m. p. 173°, and [α] −105° for the yellow light of the mercury arc, was obtained from colophony from the following sources: (1) *Pinus maritima*; (2) Aleppo pine; (3) *P. Laricio austriaca*; (4) *P. longifolia*; (5) *P. pinea*. Pimaric acid (A., 1921, i, 510), α- and β-alepic acids, and the sapinic acids are easily isomerised to abietic acid (β-pimarabietic acid) by the influence of hydrochloric acid. For these reasons, the authors do not regard abietic acid as a constituent of the natural gums, but as the final stable isomeric form of the constituents of these gums. The suggestion of Knecht and Hibbert (cf. A., 1919, i, 338) that abietic anhydride forms a constituent of colophony is rejected because abietic acid has been obtained from colophony in dry tubes at 130°, when no water was present to convert the anhydride into acid, and because abietic acid can be obtained from molten colophony in the presence of hydrogen chloride by merely seeding with a small quantity of the acid. It is suggested that the isomerisation of *l*-pimaric, α-sapinic, and β-sapinic acids takes place in two stages under the action of heat or hydrochloric acid, α-pimarabietic acid and α- and β-sapinabietic acids being formed intermediately. *d*-Pimaric acid is not isomerised under these conditions. R. B.

ααβ-Triphenylpropionic Acid and some of its Derivatives. (MLLE.) P. RAMART (*Bull. Soc. chim.*, 1924, [iv], **35**, 196—200).—A more detailed account of work already published (this vol., i, 171). S. K. T.

Calcium o-Benzyloxybenzoate. E. A. WILDMAN (U.S. Pat. 1481779).—Saponification of the product obtained by the interaction of methyl salicyate, benzyl chloride, and sodium ethoxide yields *o*-benzyloxybenzoic acid, m. p. 75°. The *calcium* salt, $Ca(O\cdot CO\cdot C_6H_4\cdot O\cdot CH_2Ph)_2$, is obtained by boiling the acid with water and calcium carbonate.

A New Iodosalicylic Acid. P. BRENANS and C. PROST (*Compt. rend.*, 1924, **178**, 1010—1012; cf. A., 1923, i, 797).—*4-Iodosalicylic acid*, colourless needles, turning brown at 200°, m. p. 228° (decomp.), was prepared from 4-nitro-*o*-toluidine by acetylation, oxidation to 4-nitroacetylanthranilic acid, deacetylation, and diazotisation to 4-nitrosalicylic acid, the ethyl ester of which was reduced; from the diazonium sulphate of the resulting amino compound hydriodic acid yielded *ethyl 4-iodosalicylate* (needles, m. p. 21°), which was hydrolysed. The *acetyl* derivative of the acid forms colourless crystals, m. p. 156°. H. J. E.

Iodinated m-Hydroxybenzoic Acids. P. BRENANS and C. PROST (*Compt. rend.*, 1924, **178**, 1285—1287).—Certain of the results obtained by the authors have been already published by Beyer (A., 1922, i, 37). The iodo-*m*-hydroxybenzoic acid, m. p. 226° (decomp.), prepared by Weselsky's method (A., 1875, 139) is identical with that obtained from 4-amino-*m*-hydroxybenzoic acid by way of the diazo compound, and is, therefore, 4-iodo-*m*-hydroxybenzoic acid. *4-Iodo-m-acetoxybenzoic acid* forms white crystals, m. p. 203°.

The iodohydroxybenzoic acid prepared from the amino-*m*-hydroxybenzoic acid obtained when 6-benzeneazo-*m*-hydroxybenzoic acid is reduced by means of stannous chloride and hydrochloric acid, is identical with that prepared from Griess' nitro-*m*-hydroxybenzoic acid (A., 1887, 485), which is hence the 6-nitro-acid. [Cf. Beyer, *loc. cit.*] T. H. P.

A New Iodo-p-hydroxybenzoic Acid. P. BRENANS and C. PROST (*Compt. rend.*, 1924, **178**, 1555—1557; cf. A., 1923, i, 1203).—The preparation of the second isomeride of iodo-*p*-hydroxybenzoic acid (2 : 4 : 1) is described. Treatment of the diazonium sulphate derived from 4-nitroanthranilic acid with potassium iodide yields 2-iodo-4-nitrobenzoic acid (cf. Willgerodt and Gartner, A., 1908, i, 877), which on reduction yields *2-iodo-4-aminobenzoic acid*, colourless needles, m. p. 188° (decomp.); *hydrochloride*, decomp. 210°; *sulphate*, white needles. The diazonium sulphate derived from this acid decomposes in aqueous solution, forming *2-iodo-4-hydroxybenzoic acid*, white, refractive needles, m. p. 215° (decomp.); *acetyl* derivative, m. p. 146°. J. W. B.

Phthalaldehydic Acid. L. SEEKLES (*Rec. trav. chim.*, 1924, **43**, 329—340).—Further details of the preparation of phthalaldehydic acid by the ozonisation of naphthalene are given (cf. A., 1923, i, 931). The normal phenylhydrazone of phthalaldehydic acid has not previously been described, as it readily loses water to form phenylphthalazone. It has now been obtained by the action of phenylhydrazine on the sodium salt of the acid. *Benzaldehydephenylhydrazone*-o-*carboxylic acid* forms a yellow precipitate, m. p. 100° (decomp.); the dark yellow *sodium* salt contains $4H_2O$, and the yellow *silver* salt turns brown in the light. Similar compounds were obtained using *p*-bromo- and *p*-nitro-phenylhydrazine. p-*Bromophenylphthalazone* forms fine, colourless needles, m. p. 169·5°; p-*nitrophenylphthalazone*, orange crystals, m. p. 259° (sintering from 228°). Hydrogen cyanide combines with the aldehydic group of phthalaldehydic acid in the normal manner, forming *o*-carboxymandelonitrile, from which *o*-carboxymandelic acid is obtained, by hydrolysis with hydrochloric acid, in the form of its lactone, phthalide-α-carboxylic acid. With acetic anhydride, phthalaldehydic acid forms a monoacetyl derivative, which must also have the phthalide structure, $C_6H_4{<}\begin{smallmatrix}CH(OAc)\\CO\end{smallmatrix}{>}O$. Its m. p. is 71°, not 60—63° as recorded elsewhere.

Comparison of the molecular refraction of phthalaldehydic acid in alcoholic solution with that of phthalide and phthalidecarboxylic acid shows that in this solvent phthalaldehydic acid has the phthalide structure, whilst in aqueous solution the aldehydic tautomeride is the more stable form. E. H. R.

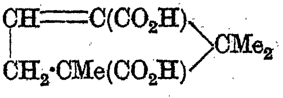
Benzylidenepyruvic Acid [Styrylglyoxylic Acid] and its Esters. I. The Action of Sunlight on Crystalline Methyl Styrylglyoxylate. M. REIMER (*J. Amer. Chem. Soc.*, 1924, **46**, 783—790).—Erlenmeyer's procedure for preparing styrylglyoxylic acid by condensing pyruvic acid and benzaldehyde in presence of sodium hydroxide (A., 1903, i, 698) has been improved and the yield increased to 80% of the theoretical. The *ethyl* ester is a yellow oil, b. p. 169—171°/7 mm.; the *methyl* ester forms long, yellow needles, m. p. 73—74°. After 1 month's exposure to sunlight, the methyl ester changes into a dimeric form, $(C_{11}H_{10}O_3)_2$, shown to be *methyl* 2 : 4-*diphenyl*cyclo*butane*-1 : 3-*diglyoxylate*,  $\begin{array}{l}Ph\cdot\underset{|}{C}H{-}\underset{|}{C}H\cdot CO\cdot CO_2Me\\ CO_2Me\cdot CO\cdot CH{-}CHPh\end{array}$, colourless crystals, m. p. 154°, which by hydrolysis yields the corresponding *acid*, m. p. about 187° (in some cases after melting at 110—116°, with evolution of gas, and again solidifying). When re-methylated with methyl alcohol, the acid gives an *ester*, $(C_{11}H_{10}O_3)_2$, m. p. 155°, not identical with the ester having m. p. 154°, but readily obtained from it by the action of hydrogen chloride in methyl alcohol. Oxidation of the above acid gives α-truxillic acid, which proves its constitution.

When methyl styrylglyoxylate dissolved in benzene is exposed to sunlight, a third isomeric *methyl* ester is obtained as colourless crystals, m. p. 117°. Hydrolysis of this ester gives an acid, m. p.

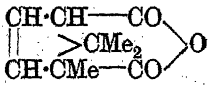
180°, which when esterified with methyl alcohol again forms the ester from which it had been produced. The free acid, when oxidised, is converted into δ-truxinic acid and is therefore concluded to be 3 : 4-*diphenyl*cyclo*butane*-1 : 2-*diglyoxylic acid.* C. J. S.

Saponins and Related Compounds. X. Urson. A. W. VAN DER HAAR (*Rec. trav. chim.*, 1924, **43**, 367—379).—The m. p. of chemically pure urson is 279—280° (cf. Dodge, A., 1919, i, 91). The generally accepted composition of urson, $C_{30}H_{48}O_3$, is incorrect, the correct formula being $C_{31}H_{50}O_3$. This formula explains the decomposition of urson, when distilled with zinc dust in a current of hydrogen, into sesquiterpenes, carbon dioxide, and water: $C_{31}H_{50}O_3 \longrightarrow 2C_{15}H_{24}+CO_2+H_2O$. The sesquiterpenes when heated with sulphur (Ruzicka's method) give an oil of which a *picrate*, m. p. 115—116°, was obtained; this is probably a picrate of a hydrocarbon of the naphthalene series, but is not identical with cadalene picrate. Urson contains one hydroxyl and one carboxyl group. *Acetylurson*, m. p. 200—201°, obtained by the action of acetic anhydride on urson, is deacetylated by boiling alcohol, consequently the "acetylurson" obtained by Gintl (A., 1893, i, 601) was urson itself. Dodge (*loc. cit.*) described a diacetylurson, and supposed urson to be a hydroxy-lactone, but his product probably contained occluded acetic anhydride. Methylation of urson takes place in the carboxyl group, giving methyl urson, which forms a *hydrate* containing $1H_2O$, m. p. 120°; anhydrous methyl urson has m. p. 165°, not 148° (cf. Nooyen, *Diss.*, Leyden, 1920). *Methyl acetylurson*, long, glistening needles, m. p. 245°, is more stable than acetylurson. The influence of the free carboxyl group on a neighbouring hydroxyl group has been also observed in the case of saponins (*e.g.*, hederagenin, A., 1922, i, 160). E. H. R.

Steric Hindrance in Bridged Rings (Bredt's Rule) and the *meso-trans*-Position in Condensed *cyclo*Hexane Ring Systems. J. BREDT, H. THOUET, and J. SCHMITZ (*Annalen*, 1924, **437**, 1—13).—The author adduces facts in agreement with his rule (cf. A., 1902, i, 374; 1913, i, 281; 1917, i, 655) that double bonds cannot exist in conjunction with the "bridge-heads" in bridged *cyclo*hexane structures. He now shows that a bridged (7-membered) ring of this kind cannot be formed. Thus, such a dicarboxylic acid as dehydrocamphoric acid (I) does not yield a simple anhydride, but gives ultimately the anhydride of *iso*dehydrocamphoric acid (II):

(I.)


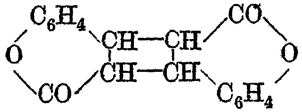
$$\left.\begin{array}{l} CH{=\!=}C(CO_2H) \\ | \\ CH_2\cdot CMe(CO_2H) \end{array}\right> CMe_2$$



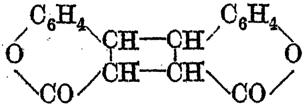
$$\left.\begin{array}{l} CH\cdot CH{-\!-}CO \\ \|\quad >CMe_2 \\ CH\cdot CMe{-\!-}CO \end{array}\right> O$$
(II.)

Silver dehydrocamphorate and dehydrocamphoryl chloride heated together produce an amorphous *dianhydride*, sintering at 120°, but having no definite m. p. Dehydrocamphoric acid heated with acetyl chloride yields the acid chloride and a *mixed anhydride*, and the latter compound is also formed when the acid is heated with acetic anhydride. It forms a syrupy mass; when heated further, it decomposes, giving a *poly-anhydride* of dehydrocamphoric acid, a vitreous substance, which when distilled in a vacuum yields *iso-dehydrocamphoric anhydride*, stout crystals, m. p. 184°. The conclusion that dehydrocamphoric acid can yield no simple anhydride is supported by steric considerations, and for these reasons the author concludes that the anhydrides obtained by Perkin (T., 1894, **65**, 572, 890) are likewise polymeric compounds. W. A. S.

Biscoumaric Acids. A. W. K. de Jong (*Rec. trav. chim.*, 1924, **43**, 316—322).—The author suggests that the biscoumarins have structures similar to those of the truxillic and truxinic acids (A., 1923, i, 574). There are thus four possible isomerides, two corresponding with the plane formula (I) and two with (II):



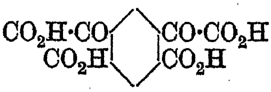
(I.)



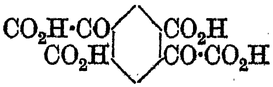
(II.)

The biscoumaric acid of Ström (A., 1904, i, 505) is formed by a method analogous to the formation of α-truxillic acid from α-cinnamic acid. It should therefore be called α-biscoumaric acid, and the biscoumarin derived from it is α-biscoumarin, m. p. 318° (decomp.). This should have formula I. It forms a *dimethyl ether*, colourless needles, m. p. 133°, which when hydrolysed gives α-biscoumaric acid dimethyl ether, m. p. 261—262°, which appears to be identical with the product obtained by Bertram and Kürsten by the action of light on coumaric acid methyl ether. When the dimethyl ether is heated with acetic anhydride, it forms *γ-biscoumaric acid dimethyl ether anhydride*, m. p. 186—187°, which when hydrolysed gives *γ-biscoumaric acid dimethyl ether*, brilliant needles, m. p. 234°. Another acid, *ε-biscoumaric acid*, m. p. 262°, was obtained by the action of fused potassium hydroxide on α-biscoumaric acid. The biscoumarin obtained by Ciamician and Silber (A., 1914, ii, 234) and called by them dihydrocoumarin, by the action of light on coumarin, is now called ζ-biscoumarin; m. p. 262°. This corresponds with formula II, and it is proposed to call the corresponding acids *biscoumarinic acids*, to correspond with the truxinic acids. *ζ-Biscoumarinic acid* is a dibasic acid, m. p. 245°, forming fine needles which soon grow into larger crystals. *Dimethyl ζ-biscoumarinate dimethyl ether* forms yellow crystals, m. p. 112—113°; *ζ-biscoumarinic acid dimethyl ether*, m. p. 134°. By heating with fused potassium hydroxide ζ-biscoumarinic acid is converted into *δ-biscoumarinic acid*, m. p. 157°. The hydrodicoumarin obtained by Dyson (*Chem. Soc. Trans.*, 1887, **51**, 66), by reducing dicoumarin with sodium amalgam, is not identical with ζ-biscoumarin, as supposed by Ciamician and Silber. By hydrolysis, it gives a monobasic acid. E. H. R.

Preparation of Pyromellitic Acid. J. von Braun and G. Lemke (*Ber.*, 1924, **57**, [*B*], 681—682).—The oxidation of octahydroanthracene with alkaline permanganate yields an acidic product of approximately the formula $C_{12}H_6O_{10}$, which is probably a mixture of the two isomeric diphthalonic acids :



and



These could not, however, be separated. Further oxidation with acid permanganate gave a nearly quantitative yield of pyromellitic acid. From 30 g. of octahydroanthracene 41 g. of practically pure pyromellitic acid were obtained. F. A. M.

Action of Aluminium Alkoxides on Mixtures of Aldehydes. N. A. Orloff (*Bull. Soc. chim.*, 1924, [iv], **35**, 360—363; cf. A., 1907, i, 282).—The action of aluminium ethoxide on three mixtures of aldehydes has been studied. Benzaldehyde and *iso*butyraldehyde gave a product from which three fractions were obtained, the first consisting of *iso*butyl *iso*butyrate, the second of *iso*butyl benzoate (19·3%) and benzyl *iso*butyrate (80·7%), and the third of pure benzyl benzoate. From a mixture of *iso*butyraldehyde and acetaldehyde, in addition to *iso*butyl *iso*butyrate, ethyl acetate, and aldolic products, a mixture, b. p. 110—117·5°, was obtained consisting of *iso*butyl acetate (75%) and ethyl *iso*butyrate (25%). Benzaldehyde and acetaldehyde gave, besides ethyl acetate, benzyl benzoate, and unchanged benzaldehyde, a mixture of benzyl acetate (96·2%) and ethyl benzoate (3·8%). The author concludes that of the two possible mixed esters, that one will be formed in larger amount in which the aldehyde of higher molecular weight yields the alcoholic component. R. B.

Catalytic Hydration of Schiff's Bases. A. Maihle (*Bull. Soc. chim.*, 1924, [iv], **35**, 379—382; cf. A., 1919, i, 395; 1920, i, 380).—Schiff's bases are easily hydrolysed when vaporised in a current of steam and passed over catalysts such as thoria and alumina heated at 400°. In this way, benzylideneaniline, for example, yields benzaldehyde and aniline. In the presence of vapours of methyl or ethyl alcohol the amine is immediately alkylated, the product of the reaction being the corresponding dialkylamine, but in the presence of higher alcohols such as propyl alcohol, alkylation does not take place. R. B.

Thermochemical Researches on Stereoisomeric Aldoximes. W. Swientoslawski and M. Popoff (*Bull. Soc. chim.*, 1924, [iv], **35**, 137—144).—Measurement of the heat evolved when sodium hydroxide or hydrochloric acid reacts with a stereoisomeric aldoxime (benzaldoxime, *m*-nitrobenzaldoxime) shows that the :N·OH group is more strongly acidic in the α-(*anti*)-aldoximes than in the β-(*syn*-)-aldoximes. The heat of solution in water is always negative, the β-isomeride having the higher absolute value.

Dry hydrogen chloride converts concentrated ethereal solutions of α-aldoxime into the β-stereoisomeride, but not always quantitatively. When a mixture of the two forms results, the α-aldoxime is in greater proportion the greater the speed of the conversion. A thermochemical method for the quantitative analysis of these mixtures is developed. Mixtures containing up to 40% of the hydrochloride of α-benzaldoxime and of α-*m*-nitrobenzaldoxime were prepared.

The heat of conversion in ether solution of α- into β-benzaldoxime is —0·98 Cal.; that for α- into β-*m*-nitrobenzaldoxime is —1·18 Cal. The heats of transformation in the free state are +2·64 Cal. ($\alpha_{\text{liq.}}$ to β_{solid}) and —1·25 Cal. (α_{solid} to β_{solid}), respectively. E. E. T.

Derivatives of *p*-Nitrobenzaldehyde. II. C. G. King and A. Lowy (*J. Amer. Chem. Soc.*, 1924, **46**, 757—762; cf. A., 1921, i, 337).—The following new *p*-nitrobenzylidene compounds have been prepared: p-*nitrobenzylidene*-o-*bromoaniline*, m. p. 106°; -m-*bromoaniline*, m. p. 102°; -2 : 6-*dibromoaniline*, m. p. 137°; -2 : 4 : 6-*tribromoaniline*, m. p. 142·5°; -3-*bromo*-4-*toluidine*, m. p. 112°; -p-*xylidine*, m. p. 100°; -o-*nitroaniline*, m. p. 169°. All form yellow needles except the last, which forms small plates.

p-Nitrobenzaldehyde condenses with 2 mols. of phenol by Danckworth's method, giving *p*-nitro-*p′p″*-dihydroxytriphenylmethane, which forms a 3′ : 5′ : 3″ : 5″-*tetrabromo* derivative,

$$NO_2{\cdot}C_6H_4{\cdot}CH{:}(C_6H_2Br_2{\cdot}OH)_2,$$

small, yellow plates, m. p. 215°; *diacetyl* derivative, m. p. 168°.

The condensation product from resorcinol and *p*-nitrobenzaldehyde gave, on bromination, a *dibromo*-p-*nitrotetrahydroxytriphenylmethane*, $NO_2{\cdot}C_6H_4{\cdot}CH{:}[C_6H_2(OH)_2Br]_2$, a yellow, amorphous powder which turns red at 170° and chars above 200°. From *o*-nitrophenol and the nitro-aldehyde was obtained 4 : 3′ : 3″-*trinitro*-4′ : 4″-*dihydroxytriphenylmethane*, $NO_2{\cdot}C_6H_4{\cdot}CH{:}[C_6H_3(OH)NO_2]_2$, an orange, amorphous powder, m. p. 177°. The condensation product obtained from thymol and *p*-nitrobenzaldehyde was brominated and gave a *dibromo* derivative, $NO_2{\cdot}C_6H_4{\cdot}CH{:}[C_6HMePrBrOH]_2$, light orange crystals, m. p. 115°; *dibenzoyl* derivative, a pale yellow, amorphous powder, m. p. 82°. C. J. S.

Electrolytic Preparation of Salicylaldehyde from Salicylic Acid. K. S. Tesh and A. Lowy (*Trans. Amer. Electrochem. Soc.*, 1924, **45**, 325—333).—Sodium salicylate is reduced electrolytically in the usual type of diaphragm cell with a mercury cathode, sodium sulphate being used as anolyte and a mixture of boric acid and sodium sulphate as catholyte. A current density of 6 amp. per sq. dm. is employed, and the temperature maintained at 15—18°; less aldehyde and more resinous matter is obtained at higher temperatures. The salicylaldehyde produced is fixed as soon as formed by progressive addition of sodium hydrogen sulphite, and is recovered by acid hydrolysis and distillation with steam. The best yield obtained is 55% of the theoretical. W. T. K. B.

Thermochemical Researches on Ketoximes. Non-stereoisomeric Ketoximes. A. Dorabialska (*Bull. Soc. chim.*, 1924, [iv], **35**, 145—152).—A thermochemical investigation of dimethyl, [illegible] and phenyl methyl ketoximes (cf. Swientoslawski and Popoff, p. 645). According to theory two stereoisomeric phenyl methyl ketoximes should exist, but only one could be obtained, treatment of ether or toluene solutions of the oxime with hydrogen chloride failing to cause any conversion. The heats of formation of the hydrochlorides of the oximes in ether solution differ but little from those of the aldoximes; they diminish with increasing acidity. Phenyl methyl ketoxime is more acidic than its constitution indicates. This is probably due to the ketoxime having the α-structure, since α-aldoximes are more acidic than the β-forms. The heat of solution of the hydrochlorides in 10% sodium hydroxide decreases as the acidity of the ketoxime increases. The heat is made up of four portions, viz., heat of solution of the hydrochloride in water (which is negative and less than that of the aldoximes), heat of decomposition (negative) of the hydrochloride into hydrochloric acid and oxime, heat of reaction of the oxime with sodium hydroxide, and heat of neutralisation of hydrochloric acid and sodium hydroxide. The parallel increase of the first two of these quantities is the cause of the decrease of the total heat with increasing acidity. E. E. T.

Ethyl Mercaptol of Phenyl Ethyl Ketone; a New Disulphone. A. Schmidt (*Bul. Soc. Chim. România*, 1924, **6**, 34—36).—On passing a stream of hydrogen chloride into a mixture of phenyl ethyl ketone (1 part) and ethyl mercaptan (2 parts) together with a small amount of anhydrous zinc chloride, the *ethyl mercaptol* of *phenyl ethyl ketone*, $CEtPh(SEt)_2$, a colourless oil of disagreeable odour, is formed. On oxidation with potassium permanganate in presence of dilute sulphuric acid, the corresponding *disulphone* is obtained in small yield as colourless, monoclinic plates, m. p. 113·5°. A. E. C.

Two Oximes of α-Ketotetrahydronaphthalene. H. Inoue (*J. Chem. Ind. Japan*, 1923, **26**, 1335—1338; cf. *Chem. Soc. Trans.*, 1899, **75**, 150).—The oxime of α-ketotetrahydronaphthalene, obtained by catalytic reduction of α-naphthol, is separated by steam distillation into a more volatile isomeride, A, colourless needles, m. p. 88—89°, and a less volatile, B, large, colourless prisms, m. p. 102—103°. By the Beckmann rearrangement, A gives B and B gives a nitrile-like liquid and another isomeric compound, C, colourless needles or prisms, m. p. 134—136°. A and B are probably stereoisomeric forms of the ketoxime. K. K.

Influence of Constitution on the Rotatory Power of Optically Active Substances. XVI. Acetylene Derivatives, Ketones, Carbylamines. H. Rupe (*Annalen*, 1924, **436**, 184—204; cf. A., 1909, i, 927).—A comparison has been made between the rotatory powers of compounds containing acetylenic linkings and the corresponding ethylenic and saturated compounds. Phenylacetylenylborneol, its dihydro- and tetrahydro-derivatives all exhibit normal rotation dispersion, and the ethylenic compound shows the greatest specific rotatory power. 1 : 2 : 2 : 3-Tetramethyl*cyclo*pentyl phenylacetylenyl ketone exhibits a large anomalous rotation-dispersion, whilst its dihydro and tetrahydro derivatives and also an isomeric ethylenic compound obtained by the condensation of 1 : 2 : 2 : 3-tetramethyl*cyclo*pentyl methyl ketone with benzaldehyde (Rupe and Kloppenburg, A., 1919, i, 539) are nearly normal. Amylcarbylamine, hexonitrile, hexylamine, and benzylidenehexylamine all exhibit anomalous rotation-dispersion, which is total in the case of the first substance. 3-Methyl*cyclo*hexylcarbylamine and 3-methyl*cyclo*hexylamine show very similar dispersions and it is doubtful whether these are normal or not. α-Camphorcarbimide exhibits an enormous specific rotation in comparison with the other members of the series.

Phenylacetylenylborneol, $C_8H_{14}<\begin{matrix}CH_2\\ C(OH)\cdot C{:}CPh\end{matrix}$, from magnesium phenylacetylenyl bromide and camphor, has b. p. 190°/13 mm. or 125—126°/0·1 mm., m. p. 44—45°, $[\alpha]_D^{20}$ −27·37° in 10% benzene solution.

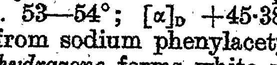
Styrylborneol, $C_8H_{14}<\begin{matrix}CH_2\\ C(OH)\cdot CH{:}CHPh\end{matrix}$, was obtained from the preceding compound by regulated reduction with hydrogen and a nickel catalyst in a mixture of aqueous alcohol and ethyl acetate. It forms a colourless, viscous oil, b. p. 183—186°/11 mm., 106—107°/0·1 mm.; $[\alpha]_D$ −107·7° in 10% benzene solution.

β-*Phenylethylborneol*, $C_8H_{14}<\begin{matrix}CH_2\\ C(OH)\cdot CH_2\cdot CH_2Ph\end{matrix}$, was obtained from the preceding compound by further reduction under identical conditions. It is a colourless, limpid oil, b. p. 176—179°/14 mm., 138—140°/0·5 mm.; $[\alpha]_D$ −25·45° in 10% benzene solution. By boiling for 12 hours with formic acid, it is dehydrated, and β-*phenylethylbornylene*, a limpid oil, b. p. 165—168°/12 mm., is formed.

Phenylacetylenylborneol, on boiling with formic acid, undergoes rearrangement to a *ketone* probably having the formula

$$C_8H_{14}<\begin{matrix}CH_2\\ C{:}CH\cdot COPh\end{matrix},$$

a yellowish-brown oil, b. p. 193—196°/12 mm., $[\alpha]_D$ −39·97° in 10% benzene solution; *semicarbazone*, white prisms, m. p. 155—156°; *phenylhydrazone*, yellow needles, m. p. 120—121°. By catalytic reduction, the ketone gives *phenyl camphanylmethyl ketone*,



$$C_8H_{14}<\begin{matrix}CH_2\\ CH\cdot CH_2\cdot COPh\end{matrix},$$

white plates, m. p. 75—76°; $[\alpha]_D$ −16·66° in 10% benzene solution; *phenylhydrazone*, yellow needles, m. p. 110—111°; *semicarbazone*, m. p. 179—181°. 1 : 2 : 2 : 3-*Tetramethyl*cyclo*pentyl phenylacetylenyl ketone*, $C_8H_{14}Me\cdot CO\cdot C{:}CPh$, was synthesised from magnesium phenylacetylenyl bromide and campholic chloride, and formed needles, m. p. 53—54°; $[\alpha]_D$ +45·38° in 10% benzene. It was also obtained from sodium phenylacetylene and campholic chloride. The *phenylhydrazone* forms white needles, m. p. 137—138°; the *hydrazone*, needles, m. p. 123—124°. On warming with methyl-alcoholic potash, the ketone gave a viscous, yellow oil, b. p. 245—247°/13 mm., apparently an additive compound with [illegible] methyl alcohol. This methoxy compound gave a *phenyl-*

hydrazone, m. p. 144—145°. 1 : 2 : 2 : 3-*Tetramethyl*cyclo*pentyl styryl ketone*, from the acetylenic compound by reduction as before, is a pale yellow, somewhat viscous oil, b. p. 192—194°/12 mm., $[\alpha]_D$ +45·31° in benzene.

Its isomeride (cf. *supra*) has $[\alpha]_D$ +54·24° in 10% benzene solution. 1 : 2 : 2 : 3-Tetramethyl*cyclo*pentyl β-phenylethyl ketone may be obtained by the reduction of the acetylenic ketone (b. p. 178—181°/12 mm.; $[\alpha]_D$ +40·51° in 10% benzene solution) or of Rupe and Klottenburg's ketone (b. p. 188—189°/13 mm.; $[\alpha]_D$ +48·24° in 10% benzene solution), as well as by the method of Rupe and Jäggi (A., 1922, i, 840); (b. p. 178—181°/10 mm. and $[\alpha]_D$ +38·84° in 10% benzene solution).

Active amylcarbylamine has b. p. 137—138°/745 mm.; $[\alpha]_D$ +0·35° in benzene solution. Hexonitrile, hexylamine, and benzylidenehexylamine have $[\alpha]_D$ +0·76°, 0·86°, 1·41°, respectively. *Methyl*cyclo*hexylamine*, from the oxime of 3-methyl*cyclo*hexanone, has $[\alpha]_D$ −2·09°. By the action of chloroform and potassium hydroxide, 3-*methyl*cyclo*hexylcarbylamine* was obtained as an oil, b. p. 67—69°/10 mm.; $[\alpha]_D$ −0·77°. *Benzylidenehexylamine* is a colourless liquid, b. p. 130—132°/13 mm. A. E. C.

Equilibrium between Benzaldehyde and Benzoin. A. Lachman (*J. Amer. Chem. Soc.*, 1924, **46**, 708—723).—The condensation of 2 mols. of benzaldehyde to give 1 mol. of benzoin requires the combined action of hydroxyl and cyano ions. These catalysts also reverse the condensation, but at the same time they convert benzoin into benzyl benzoate and benzoic acid, this step not being reversible. When benzoin is heated at 300°, it is partly converted into benzaldehyde; under the same conditions, benzaldehyde yields no benzoin, but forms benzyl benzoate, benzoic acid, toluene, and dibenzyl ether. The benzoin and Cannizzaro condensations can be accounted for by two assumptions. Benzaldehyde combines with M·OH(or ·OR) to form the compound CHPh(OM)(OH) (A), in which ·OH is the more labile group; and with hydrogen cyanide to form CHPh(CN)(OH) (B), in which H is more labile. A reacts with benzaldehyde by transfer of hydroxyl to yield benzyl benzoate; it reacts with B according to the equation CHPh(CN)(OH) + CHPh(OH)(OK) = CPh(CN)(OK)·CH(OH)Ph + H_2O; if both benzaldehyde and B are present, it reacts with both; if A is absent, as in acidified solutions, benzoin fails to form. The unique function of the cyano ion as the only catalyst which will convert benzaldehyde into benzoin also becomes clearer. Benzaldehyde forms additive products of the general type CHPh(OH)(X) with sodium hydrogen sulphite, hydrogen chloride, and hydrogen cyanide, but of these the last is the only one capable of existing under conditions necessary for the presence of A, *i.e.*, alkaline solution. A method is described for preparing benzoin without the use of alcohol. C. J. S.

Optically Active β-Phthalimino-β-phenylpropiophenones. A. McKenzie and T. M. A. Tudhope (*J. Chem. Soc.*, 1924, **125**, 923—930; cf. *ibid.*, 1921, **119**, 69).—In the preparation of *r*-β-amino-β-phenylpropionic acid from hydroxylamine and cinnamic acid (cf. A., 1905, i, 577), besides acetophenoneoxime, 3-phenyl*iso*-oxazolone, m. p. 149—151°, is produced (cf. A., 1906, i, 955; 1912, i, 453). *r*-β-Phthalimino-β-phenylpropionic acid was resolved into its optically active components with cinchonine in rectified spirit. From the more sparingly soluble cinchonine salt was separated d-β-*phthalimino*-β-*phenylpropionic acid*,

$$C_6H_4{:}C_2O_2{:}N{\cdot}CHPh{\cdot}CH_2{\cdot}CO_2H,$$

glassy rosettes, m. p. 150—151°, having $[\alpha]_D$ $-5{\cdot}5°$ in ethyl acetate, and $-2{\cdot}2°$ in ethyl alcohol. The same active acid was obtained by the resolution of *r*-β-amino-β-phenylpropionic acid (cf. A., 1910, i, 622) and heating the *d*-amino-acid with phthalic anhydride. In spite of its lævorotation in ethyl acetate, this acid is accordingly designated as *d*-β-phthalimino-β-phenylpropionic acid, taking *d*-β-amino-β-phenylpropionic acid as the reference compound. In methyl alcohol, the phthalimino acid is slightly dextrorotatory. Thionyl chloride converts the *d*-phthalimino acid into its acid chloride from which, by the Friedel-Crafts reaction, is obtained d-β-*phthalimino*-β-*phenylpropiophenone*,

$$C_6H_4{:}C_2O_2{:}N{\cdot}CHPh{\cdot}CH_2{\cdot}COPh,$$

m. p. 116—117°, $[\alpha]_D^{15}$ $-127{\cdot}1°$ in benzene and $[\alpha]_D^{13}$ $-96{\cdot}2°$ in acetone. l-β-*Phthalimino*-β-*phenylpropiophenone* was similarly obtained from the *l*-phthalimino acid. Hydrolysis of the lævorotatory *d*-ketone with alcoholic sodium hydroxide yields d-β-*benzoyl*-α-*phenylethylphthalamic acid*, $COPh{\cdot}CH_2{\cdot}CHPh{\cdot}NH{\cdot}CO{\cdot}C_6H_4{\cdot}CO_2H$, feathery crystals, m. p. 147—147·5°, $[\alpha]_D^{16{\cdot}5}$ $+38{\cdot}8°$ in ethyl alcohol, which on hydrolysis with a mixture of concentrated hydrochloric acid and glacial acetic acid yields phthalic acid and the lævorotatory *d*-β-phthalimino-β-phenylpropiophenone, dehydration as well as hydration of the phthalamic acid taking place. R. B.

Migration of Groups in Derivatives of Benzoin and Desylamine. A. McKenzie and R. Roger (*J. Chem. Soc.*, 1924, **125**, 844—854; cf. A., 1923, i, 213, 333, 788).—The dehydration of methylhydrobenzoin with concentrated sulphuric acid yields a methyldeoxybenzoin, m. p. 50—52° (cf. Tiffeneau and Orékhov, A., 1920, i, 672; 1921, i, 565; Lévy, A., 1921, i, 860), from which two semicarbazones were obtained, m. p. 213—215° (cf. A., 1920, i, 672) and 159—160°. The methyldeoxybenzoin thus appears to exist in two forms, one melting at 50—52° (cf. A., 1888, 703) and the other at 58—59°. Both forms are converted into ααβ-triphenyl-α-propanol, m. p. 88—89°, with magnesium phenyl bromide. A small amount of *as*-diphenylacetone is also formed in the dehydration of the glycol as a result of slight semipinacolin transformation. The dehydration of αα-diphenylpropane-αβ-diol with either dilute or concentrated sulphuric acid (cf. A., 1906, i, 724) yields *as*-diphenylacetone: $OH{\cdot}CPh_2{\cdot}CHMe{\cdot}OH \longrightarrow CHPh_2{\cdot}COMe$, vinyl dehydration being the only change which occurs. The ketone has m. p. 58·5—59·5° and its semicarbazone m. p. 169—170° (cf. A., 1906, i, 581). β-Hydroxy-αβ-diphenylpropylamine on treatment with sodium nitrite in acetic acid solution undergoes semipinacolinic deamination and yields *as*-diphenylacetone, m. p. 45—47° when freshly prepared, rising to 58—59° after 4 weeks. The transformation: $OH\cdot CPhMe\cdot CHPh\cdot NH_2 \longrightarrow COMe\cdot CHPh_2$, is in marked contrast to the vinyl dehydration of methylhydrobenzoin: $OH\cdot CPhMe\cdot CHPh(OH) \longrightarrow CHPhMe\cdot COPh$. Other examples of the action of nitrous acid on amino-alcohols cited by McKenzie and Richardson (T., 1923, **123**, 79) are interpreted on similar lines. In the light of this work, the product, $C_{21}H_{18}O$, m. p. 121·5—122°, obtained by McKenzie and Richardson by the action of nitrous acid on γ-hydroxy-αγγ-triphenyl*iso*propylamine,

$$CH_2Ph\cdot CH(NH_2)\cdot CPh_2\cdot OH,$$

is benzyldeoxybenzoin (cf. Meyer and Oelkers, A., 1888, 703), semipinacolinic deamination taking place. A further example of this change is the conversion by nitrous acid of β-hydroxy-αββ-triphenylethylamine into phenyldeoxybenzoin.

The dehydration of αβ-diphenyl-β(α-naphthyl)-ethane-αβ-diol, m. p. 204—205° (cf. A., 1904, i, 742), with dilute sulphuric acid yields a compound, $C_{24}H_{18}O$, m. p. 180—181°, probably the ethylenic oxide,  $O<\begin{matrix}CHPh\\ |\\ CPh\cdot C_{10}H_7\end{matrix}$. Concentrated sulphuric acid yields an isomeride, m. p. 108—109°, identical with the product obtained by the action of nitrous acid on β-hydroxy-αβ-diphenyl-β-naphthylethylamine (T., 1923, **123**, 79). R. B.

Stereochemical Investigations in the Phenyl Styryl Ketone Series. Certain Derivatives of Dibenzoylmethane and of Phenyl Styryl Ketone. C. DUFRAISSE and A. GILLET (*Compt. rend.*, 1924, **178**, 948—950).—The phenyl β-alkoxystyryl ketones, $COPh\cdot CH{:}CPh\cdot OR$ (A., 1923, i, 113) combine with bromine without forming any appreciable proportion of hydrogen bromide, but the dibromo compounds obtained, $COPh\cdot CHBr\cdot CBr(Ph)\cdot OR$, are extremely sensitive to the action of moisture and undergo immediate transformation into bromodibenzoylmethane, $COPh\cdot CHBr\cdot COPh$. When special precautions are taken, it is, however, possible to replace by a second alkoxy group the bromine atom of the $\cdot CBr(Ph)\cdot OR$ group. In this way, good yields of the following monoacetals of bromodibenzoylmethane were obtained: *phenyl α-bromo-ββ-dimethoxy-β-phenylethyl ketone*, $CHBrBz\cdot CPh(OMe)_2$, m. p. 91°; corresponding *diethoxy* compound, $CHBrBz\cdot CPh(OEt)_2$, m. p. 72°; *dipropoxy* compound, $CHBrBz\cdot CPh(OPr)_2$, m. p. 84°. Of the two possible racemic compounds represented by the formula, $CHBrBz\cdot CPh(OMe)\cdot OEt$, only one, m. p. 90°, has yet been obtained.

These acetals are white compounds and are particularly sensitive towards acids, which convert them immediately into bromodibenzoylmethane. When heated, they lose 1 mol. of an alcohol giving pale yellow phenyl α-bromo-β-alkoxystyryl ketones, of which the following have been prepared: *phenyl α-bromo-β-methoxystyryl ketone*, $CBrBz{:}CPh\cdot OMe$, m. p. 72° (stable form); corresponding β-*ethoxy* compound, $CBrBz{:}CPh\cdot OEt$, m. p. 76° (stable form); and β-*propoxy* compound, $CBrBz{:}CPh\cdot OPr$, m. p. 49°.

These undergo hydrolysis when heated with a dilute acid, bromodibenzoylmethane being formed. The action on them of an alkali alkoxide results in the fixation at the double linking of an alcohol molecule, the resulting monoacetals being either symmetrical or unsymmetrical.

The phenyl α-bromo-β-alkyloxystyryl ketones are prone to exist in several forms, each having characteristic crystallographic constants, melting point, and solubility. Thus, the methoxy compound exhibits two forms, m. p. 64° and 72°, and the ethoxy compound, three forms, m. p. 65°, 73°, and 76°. The form with the highest melting point is the most stable, and when it has once made its appearance in a laboratory, the preparation there of the other form or forms is impossible unless the precautions employed in obtaining pure cultures of bacteria are taken.

The unstable form of phenyl α-bromo-β-methoxystyryl ketone, m. p. 64°, is isomorphous with the stable form of phenyl αβ-dibromostyryl ketone, m. p. 80°, and with the unstable form, m. p. 71°, of one of the di-iodo derivatives of phenyl styryl ketone. T. H. P.

Stereoisomeric Semicarbazones. F. J. Wilson and R. M. Macaulay (*J. Chem. Soc.*, 1924, **125**, 841—844; cf. *ibid.*, 1912, **101**, 1482; 1913, **103**, 377, 1504).—By exposure to ultra-violet light dypnone semicarbazone, $CPhMe{:}CH{\cdot}CPh{:}N{\cdot}NH{\cdot}CO{\cdot}NH_2$, m. p. 151°, has been converted into a second of the four stereoisomerides required by theory. The new semicarbazone, m. p. 175—176°, is obtained in a yield of 33% of theory, and partial reconversion is effected on further exposure. Similarly, the δ-phenylsemicarbazone of mesityl oxide, m. p. 134°, yields about 33% of a more soluble *stereoisomeride*, m. p. 99—101°, reconversion being accomplished by heating in alcoholic solution. The semicarbazone of phenyl β-phenylstyryl ketone, m. p. 171—172° (cf. A., 1916, i, 821) yields, in the same way, the second stereoisomeric carbazone required by theory, a pale yellow, microcrystalline powder, m. p. 204—205°, partial transformation of either stereoisomeride taking place on exposure in alcoholic solution. Attempts to obtain a stereoisomeride of styryl *iso*butenyl ketone semicarbazone, $CMe_2{:}CH{\cdot}C({:}N{\cdot}NH{\cdot}CO{\cdot}NH_2){\cdot}CH{:}CHPh$, m. p. 168°, were unsuccessful. In the preparation of the semicarbazone, a small quantity of a substance, m. p. 221—222°, possibly the semicarbazide-semicarbazone,

$$CMe_2(NH{\cdot}NH{\cdot}CO{\cdot}NH_2){\cdot}CH_2{\cdot}C({:}N{\cdot}NH{\cdot}CO{\cdot}NH_2){\cdot}CH{:}CHPh,$$

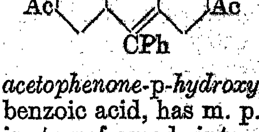
was obtained. Attempts to obtain stereoisomerides of the semicarbazones of benzylacetone, benzylacetophenone, and styryl methyl ketone were also unsuccessful. R. B.

Indones. V. Conversion of 3-Phenyl-2-methylindone into Diphenyldimethyltruxones by the Action of Ultra-violet Rays. [illegible] Fazi (*Gazzetta*, 1924, **54**, 85—88; cf. A., 1920, i, 316; 1921, [illegible]—It has been shown previously that, when treated with concentrated sulphuric acid, ethyl β-hydroxy-ββ-diphenyl-α-methylpropionate yields 3-phenyl-2-methylindone, whereas ethyl β-hydroxy-ββ-diphenylpropionate gives 3-phenylindone and the two diphenyltruxones (A., 1915, i, 1063; 1916, i, 151; 1920, i, 316; 1921, ii, 357). Under the same conditions, 3-phenyl-2-methylindone yields no truxone, but may be recovered unchanged from the emerald-green solution formed.

The two *diphenyldimethyltruxones* (cf. A., 1920, i, 317) are, however, formed when a benzene solution of 3-phenyl-2-methylindone is subjected in a quartz tube to the influence of the ultraviolet light from a quartz mercury vapour lamp. The first *isomeride* forms pale, canary-yellow crystals, m. p. 259—260°; the second *isomeride* forms white crystals, m. p. 307—308°, appears to be phototropic, and, after repeated crystallisation from alcohol, yields 3-phenyl-2-methylindone when treated with concentrated sulphuric acid. T. H. P.

The Benzil Rearrangement. VI. A. LACHMAN (*J. Amer. Chem. Soc.*, 1924, **46**, 779—782; cf. A., 1923, i, 784, 785).—In the benzil rearrangement there are two opposing reactions: one, consisting of intramolecular oxidation and reduction, giving benzilic acid; and the other, a process of rupture, producing benzaldehyde and ethyl benzoate. The first reaction will not occur in the absence of water, but a much smaller quantity of water will suffice if ether is used as a part of the solvent, and if potassium hydroxide is employed in place of sodium hydroxide. As the proportion of water increases, less benzoic acid, but more benzilic acid, results. Schönberg and Keller (A., 1923, i, 928) ascribe the formation of benzoic acid during the benzil rearrangement to oxidation by atmospheric oxygen, but it is shown that such an action does not occur. C. J. S.

Condensation of Benzoic Acid and Substituted Benzoic Acids with Resacetophenone. G. C. CHAKRAVARTI (*J. Amer. Chem. Soc.*, 1924, **46**, 682—685).—A number of dyes belonging to the benzein series have been prepared by heating, in presence of anhydrous zinc chloride, 2 mols. of resacetophenone with rather more than 1 mol. of benzoic or a substituted benzoic acid. The dyes show strong fluorescence in alkaline solution and yield colourless acetyl derivatives. Benzoic acid condensed with resacetophenone gives *resacetophenonebenzein* (annexed formula), forming rose-red crystals, m. p. 141°; *acetyl* derivative, m. p. 125°. *Resacetophenone-p-hydroxybenzein*, $C_{23}H_{18}O_6,4H_2O$, from *p*-hydroxybenzoic acid, has m. p. 107—108°, and when kept for several weeks is transformed into a "homochromo-isomeride," m. p. 192°; *acetyl* derivative, m. p. 102°. Salicylic acid yields a *benzein*, m. p. 133—135° (*acetyl* derivative, m. p. 128°). The *benzeins* obtained from anisic acid, *m*-bromobenzoic acid, and gallic acid have m. p. 161°, 147°, and 126°, respectively. Similarly constituted products of high m. p. are obtained from *m*- and *p*-nitro- and *p*-chlorobenzoic acids. C. J. S.



Constitution of Biochemically Formed Hydroxyketopropylbenzene. C. NEUBERG (*Biochem. Z.*, 1924, **144**, 44—46).—A reply to Auwers and Jordan (this vol., i, 384). It is pointed out that the structure ascribed by these authors to the β-ketol is in agreement with the views of Neuberg and Ohle, and that the exact constitution of the product formed by the action of carboligase in the presence of benzaldehyde is of little importance to the biological aspect of the activity of the enzyme. J. P.

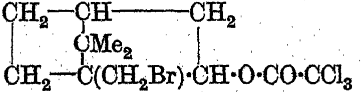
Functions of Chromophores. IX. The Quinone Chromophore. I. J. LIFSCHITZ, H. LOURIÉ, J. ZIMMERMANN, and G. A. TEN BOKKEL HUININK (*Rec. trav. chim.*, 1924, **43**, 269—282; cf. A., 1921, ii, 286, 287).—The absorption spectrum of *p*-benzoquinone in alcoholic solution consists of three bands with maxima at 2150 (A), 3400 (B), and 4400 (C). These bands may be assumed to correspond with the three groups of absorption bands of the vapour spectrum, and may therefore be attributed to different species of electrons or different groups of atoms. Substitution of the hydrogen atoms of *p*-benzoquinone by alkyl groups, as in toluquinone and *p*-xyloquinone, moves A without weakening it towards shorter wave-lengths, B and C in the opposite direction. Unsaturated hydrocarbon groups, as in anthraquinone, weaken A and strengthen B. Chlorine has a similar effect, but influences C irregularly. Chloranil owes its intense yellow colour to the broadening of B. Auxochromic groups having no residual valency, such as the ethoxy group, have a similar effect to chlorine, but intensified, whilst auxochromic groups having residual valency (·OH and ·NR$_2$) have such an extreme effect as to give the substance the character of a dyestuff. From the effect of chlorine on band A it is argued that this band is associated with the carbon atoms, since chlorine has the effect of weakening the conjugated system of the carbonyl groups and ethylenic linkings. This deduction is supported by the fact that A is strengthened and deepened in polynuclear quinones. Band B is attributed to the oxygen electrons, since the broadening of this band by alkyl groups and its shifting towards the red by halogens is similar to the effect of these radicals on the oxygen band of acetone. E. H. R.

Quinhydrone Salts. S. GOLDSCHMIDT and F. CHRISTMANN (*Ber.*, 1924, **57**, [*B*], 711—715).—The sodium salt of *p*-benzoquinhydrone, $C_6H_4O_2+C_6H_4O_2Na_2$, was obtained practically pure by treating a mixture of quinone and quinol with sodium ethoxide in dry ethereal solution; it formed a deep blue precipitate sufficiently stable, when dry, to be weighed in air. The blue *sodium salt* of o-*benzoquinhydrone* was obtained in a similar manner, in complete absence of air or moisture. Both salts are at once decomposed by water to give greenish-yellow or brown solutions respectively. The *sodium* salt of *phenanthraquinhydrone* was obtained as a deep green precipitate by dissolving phenanthraquinone in alcohol or pyridine, adding 10% sodium hydroxide and [illegible] sodium chloride solution, and then blowing in oxygen. It is practically insoluble in water in absence of air, but dissolves in pyridine to a deep green solution. The corresponding *barium* salt was also prepared. On treating a benzene solution of phenanthraquinol with lead dioxide, an emerald-green solution is obtained which is believed to contain a complex salt of the type ($xC_8H_{14}O_2+$ $yC_8H_{14}O_2Pb$). F. A. M.

Direct Amination of Anthraquinone. J. KNIATOWNA (*Bull. Soc. chim.*, 1924, [iv], **35**, 207—211).—According to a German patent (D.R.-P. 287756), the product obtained by heating anthraquinone with hydroxylamine sulphate in concentrated sulphuric acid, in presence of ferrous sulphate for 2 hours at 180—190°, is practically pure 1-aminoanthraquinone. This claim cannot be substantiated. Only a very small portion of the product dissolves in hydrochloric acid, and the residue, after repeated crystallisation, gives anthraquinone. From the mother-liquors of these crystallisations molecular compounds of anthraquinone and aminoanthraquinone are obtained which melt between 253° and 271°. The formation of such compounds may be the cause of the contradictory values given in the literature for the melting point of 1-aminoanthraquinone. E. E. T.

Anthraquinonylsemicarbazides. M. BATTEGAY and P. DASSIGNY (*Bull. Soc. chim.*, 1924, [iv], **35**, 211—213).—Dianthraquinonylsemicarbazides are prepared by boiling together nitrobenzene solutions of β-anthraquinonylcarbamyl chloride and α- or β-anthraquinonylhydrazine. ββ'-*Dianthraquinonyl*-1:4-*semicarbazide*, $\beta\text{-}C_{14}H_7O_2\cdot NH\cdot NH\cdot CO\cdot NH\cdot\beta\text{-}C_{14}H_7O_2$, is an orange substance which turns orange-yellow at 300°, sublimes, and leaves a residue melting above 330°. αβ'-*Dianthraquinonyl*-1 : 4-*semicarbazide* is a reddish brown substance which turns orange at 270—275° and melts at about 310°. Both these compounds dye cotton from a hyposulphite vat, but the dyeings are irregular owing to partial decomposition taking place in the bath. E. E. T.

Constitution of so-called β-Bromocamphor. P. LIPP and F. LAUSBERG (*Annalen*, 1924, **436**, 274—286).—Although Wedekind, Schenk, and Stüsser have shown (A., 1923, i, 346) that Reychler's camphorsulphonic acid is an ω-derivative, the formation of "β"-bromocamphor from camphorsulphonyl bromide (*Chem. Soc. Proc.*, 1901, **17**, 244, 245) affords no proof of the ω-constitution of the bromocamphor owing to the possibility of isomeric change. The authors have accordingly attempted the preparation of "β"-bromocamphor from compounds containing the bromine atom in the ω-position. *d*-Camphene was converted into ω-bromocamphene, which by digestion with trichloroacetic acid at 40° yields the well-crystallised *trichloroacetate* (annexed formula), which was obtained in two stereoisomeric forms, m. p. 80° and 101—102°. On hydrolysis, the expected ω-bromo-borneol or -*iso*borneol was not obtained but by reduction with sodium amalgam in alcoholic solution the ester yields the α-campholen-



$$\begin{array}{lll} CH_2\text{—}CH & \text{———} & CH_2 \\ | \quad\quad CMe_2 & & | \\ CH_2\text{—}C(CH_2Br)\cdot & & CH\cdot O\cdot CO\cdot CCl_3 \end{array}$$

aldehyde of Ciamician and Silber (A., 1910, i, 496), b. p. 93·5—96°/19 mm. (*semicarbazone*, m. p. 160—162°). The aldehyde is easily resinified by alkalis and a resinous *substance*, $(C_{10}H_{16}O)_n$, b. p. 165—175°/4 mm., was isolated as a by-product in the reduction. On oxidation with nitric acid, *d*-ω-2-dibromocamphane gives an acid, $C_{10}H_{15}O_4Br$, m. p. 208—210°, an oily product containing nitrogen and halogen, which yields a yellow potassium salt, and a neutral substance, probably  $C_8H_{13}Br<\begin{matrix}CH_2\\ |\\ CH_2\cdot NO_2\end{matrix}$. The acid is identical with the "β"-bromocamphoric acid obtained by the oxidation of "β"-bromocamphor, the identity being confirmed by a comparison of the anhydrides. The m. p. of ω-bromocamphoric anhydride is given as 149—150° (cf. P., 1901, **17**, 244). *dl*-ω-2-Dibromocamphane similarly gives *dl*-ω-bromocamphoric acid (decomp. 208—210°), and the corresponding anhydride, m. p. 149—149·5°. For comparison *dl*-ω-camphorsulphonic acid was prepared from synthetic camphor by Reychler's method (A., 1899, i, 445) and from this, by Armstrong and Lowry's procedure, the *dl*-ω-bromocamphor, m. p. 76—77°, was obtained. On oxidation with nitric acid, this yields *dl*-ω-bromocamphoric acid, m. p. 210—211°, and anhydride, m. p. 149—150°, identical with the products obtained from *dl*-ω-2-dibromocamphane, and the authors accordingly assign the ω-structure to "β"-bromocamphor. R. B.

Optically Active Sulphilimines. F. G. Mann and W. J. Pope (*J. Chem. Soc.*, 1924, **125**, 911—918).—Attempts have been made to prepare sodium *d*-α-bromocamphor-π-sulphonchloroamide and by condensation with methyl ethyl sulphide to obtain the corresponding sulphilimine, $C_{10}H_{14}OBr\cdot SO_2N{:}SMeEt$, which, owing to the trihedral disposition of the three valencies of the doubly-linked nitrogen atom, should exist in two enantiomorphous forms. *d*-Bromocamphor-π-sulphonamide, on treatment with sodium hypochlorite, gives d-*bromocamphor-π-sulphondichloroamide*,

$$C_{10}H_{14}OBr\cdot SO_2\cdot NCl_2,$$

white crystals, m. p. 123—125°, which slowly lose chlorine on standing. No sodium or potassium salt could be obtained, and by treatment with alcoholic potassium hydroxide (either with or without ethyl sulphide) the dichloroamide yielded unchanged α-bromocamphor-π-sulphonamide and d-*α′-chloro-α-bromocamphor-π-sulphonamide*, $C_{10}H_{13}OClBr\cdot SO_2\cdot NH_2$, colourless needles, darkening at 225°, m. p. 232° (decomp.) (cf. Lapworth, T., 1899, 75, 558). For comparison, the d-*α-chloro-α′-bromocamphor-π-sulphonamide*, colourless needles, darkening at 224°, m. p. 232° (decomp.), was prepared by brominating ammonium *d*-α-chlorocamphor-π-sulphonate, treating the product with phosphorus pentachloride, yielding d-*α-chloro-α′-bromocamphor-π-sulphonyl chloride*, colourless crystals, m. p. 194—197° (effervescence), which with ammonia gives the sulphonamide. The two sulphonamides differ only in rotatory constants. d-*α-Bromocamphor-π-sulphonethylchloroamide*, $C_{10}H_{14}OBr\cdot SO_2\cdot NEtCl$, white crystals, m. p. 122—124° (efferv.), from *d*-α-bromocamphor-π-sulphonyl chloride and ethylamine is more stable than the dichloroamide, and can be crystallised from alcohol.

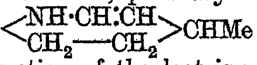
Sodium ethyl sulphide condenses with *d*-chloromethylenecamphor, giving *ethylthiolmethylene*-d-*camphor*, $C_{10}H_{14}O{:}CH\cdot SEt$, pale green liquid, b. p. 169—171°/17 mm., $d_{4^\circ}^{14\cdot 8}$ 1·0362. *Ethylthiolmethylene*-l-*camphor*, obtained similarly, is a pale green liquid, b. p. 168—169°/16 mm., $d_{4^\circ}^{15\cdot 0}$ 1·0357. Both sulphides condense with hydrated "chloramine-*T*" in boiling alcohol to give d- and l-*camphorylidene-methylethylsulphine*-p-*toluenesulphonylimine*,

$$C_{10}H_{14}O{:}CH\cdot SEt{:}N\cdot SO_2\cdot C_7H_7,$$

white crystals, m. p. 172° (efferv.). The rotatory powers of these sulphilimines are less than those of the parent substances, and no indication was obtained of the expected stereoisomerism. Rotatory powers are given for all the above compounds. R. B.

The Beckmann Rearrangement. X. S. Komatsu (*Mem. Coll. Sci. Kyōtō*, 1924, **7**, 147—150).—The author cites various examples of the Beckmann change and of nitrile formation, and points out that the latter reaction may be due to direct elimination of water from the oxime or to dehydration after the Beckmann change. C. J. S.

The Beckmann Rearrangement. XI. Catalytic Action of Reduced Copper on *l*-Menthoneoxime. S. Komatsu and M. Kurata (*Mem. Coll. Sci. Kyōtō*, 1924, **7**, 151—156).—When *l*-menthoneoxime and pure hydrogen were passed over reduced copper at 200°, the product contained menthone, dimenthylamine, *l*-menthylamine, *d*-menthylamine, menthonitrile, decenoic acid and its amide, and a basic substance, probably 4-methyl-7-*iso*propyl-*cyclo*hexenimine,



$Pr^{\beta}\cdot CH<\begin{matrix}NH\cdot CH{:}CH\\ CH_2\text{---}CH_2\end{matrix}>CHMe$ (cf. Wallach, A., 1903, i, 104). The production of the last is regarded as evidence of the momentary formation of menthone*iso*oxime, which undergoes the Beckmann rearrangement by catalytic action of the reduced copper. The menthonitrile and decenoic acid are supposed to be formed respectively by catalytic dehydration and hydration of decenamide. C. J. S.

Camphor Oils. I. Reaction between Camphor-red Oil and Sulphuric Acid. K. Ono (*Mem. Coll. Sci. Kyōtō*, 1924, **7**, 99—105).—According to Sugiyama (Japanese Pat. 37119, 1920), terpin hydrate is obtained when camphor-red oil is treated with sulphuric acid. The author shows that this result is due to the action of the acid on the terpineol present in the oil (cf. Aschan, A., 1919, i, 336) and gives the conditions to be employed in order to obtain the optimum yield of terpin hydrate. [Cf. *B.*, 1924, 447.] T. H. P.

Origin of Terpenes and Crystalline Acids in Pine Resins. G. Dupont (*Compt. rend.*, 1924, **178**, 1560—1562).—The hypothesis that the terpenes and resin acids in conifers have a common origin in a material secreted by the resin cells is developed. The secreted material, which has the formula $C_{10}H_{16}O$ (Köhler, A., 1912, i, 638), is converted by the action of a diastase into the terpene, $C_{10}H_{16}$, and the oxygen acting on two other molecules produces the resin acids, $3C_{10}H_{16}O=C_{10}H_{16}+C_{20}H_{30}O_2+H_2O$. This requires that the refined turpentine should contain 31% of the essential oil and 69% of resin acids, numbers which are in close agreement with the proportions actually found. The proportions of *d*- and *l*-pimaric acids and resin acids in the extract of the maritime pine, the fact that *d*-pimaric acid is found only in turpentines rich in nopinene, whilst the Aleppo pine, which yields only pinene, gives an extract containing alepic acid only, all support the hypothesis. J. W. B.

Eutectics of Camphene with other Terpenes. G. AUSTERWEIL (*Compt. rend.*, 1924, **178**, 1174—1175).—The separation of camphene from other terpenes (when the former is not present in excess of 30% of the mixture) by crystallisation at a low temperature is rendered impracticable by the formation of eutectic mixtures of low freezing point, which are comparatively rich in camphene. The melting points of a series of mixtures of camphene with α-pinene, β-pinene, mixtures of α- and β-pinene, and dipentene are given. H. J. E.

Melting Points of Mixtures of Camphene and Pinene. E. DARMOIS (*Compt. rend.*, 1924, **178**, 1546).—Austerweil's conclusion (preceding abstract) that French turpentine contains practically no camphene and that the low melting points of natural camphenes are explained by the presence of small quantities of impurities, was anticipated by the author (A., 1911, ii, 352). J. W. B.

Phellandrenes. II. H. G. SMITH, P. G. CARTER, and J. READ (*J. Chem. Soc.*, 1924, **125**, 930—940; cf. *ibid.*, 1923, **123**, 1657).—By solution in carbon disulphide, in which the α-nitrite is relatively insoluble, and fractional precipitation, the β-nitrite of *l*-α-phellandrene has been prepared from the essential oils of *Melaleuca acuminata*, *Eucalyptus dives*, and *E. phellandra* in a much higher state of purity than has hitherto been attained. The process of separation can only be controlled effectively by considering the melting points of the various fractions in association with the corresponding rotatory powers. The β-nitrite, m. p. 105—106°, is crystallographically indistinguishable from *l*-α-phellandrene α-nitrite, and has $[\alpha]_D^{20}$ −160° when freshly dissolved in chloroform, the values previously recorded being −36° (Schreiner, A., 1901, i, 600) and −40·82° (Wallach, A., 1904, i, 1035). The striking mutarotative changes of the β-nitrite in acetone, benzene, or chloroform solution, particularly in the presence of piperidine, are similar to those previously observed with the α-nitrite, but optical inversion only takes place in acetone solution. The α- and β-nitrites yield chemically and optically identical specimens of nitro-α-phellandrene and carvotanacetone ($\Delta^{5,6}$-menthen-3-one), and are thus both derived from *l*-α-phellandrene. It is probable that the low rotatory powers of the terpene fractions obtained from eucalyptus oils of the "peppermint group" are due to the presence of partly racemised *l*-α-phellandrene, and a similar remark applies to the essential oil of *Melaleuca acuminata*. R. B.

Oil of Turpentine extracted from the Firs of Bucovina. O. CZERNY (*Bul. Soc. Chim. România*, 1924, **6**, 39—41).—By submitting the greenish-yellow oil obtainable from the bark of the tree to distillation in a current of steam, an oil was obtained which after treatment with sodium hydroxide and subsequent distillation under diminished pressure, had b. p. 155—216°, d^{16} 0·875, $[\alpha]_D$ −39·2°, acid value 124, saponification value 107, esterification value 13. It was separated by fractional distillation into pinene, a mixture of sylvestrene and dipentene, an ester which on hydrolysis with alcoholic potassium hydroxide yielded borneol, and, probably, a sesquiterpene. The non-volatile residue from the steam distillation, amounting to some 75% of the total weight, was a hard, brittle solid, m. p. 55°, which on distillation yielded traces of acetic and succinic acids and a large amount of coloured oils of very low oxygen content. A. E. C.

Refractive Index of Gums. A. MALLOCK (*Nature*, 1924, **113**, 643).—A corrected table of refractive indices of certain organic solvent liquids and gums is given. A. A. E.

Method for obtaining Pure Glucosides Soluble in Water from Plants. S. GHOSH (*J. Amer. Pharm. Assoc.*, 1923, **12**, 1080—1081).—Steam is passed into an aqueous extract of the bark to which lead chloride and oxide have been added; lead remaining in solution after addition of sodium carbonate and filtration is removed with hydrogen sulphide. Sodium chloride can, if necessary, be removed from the product obtained on evaporation by recrystallisation from ethyl alcohol. CHEMICAL ABSTRACTS.

Nature of the Methyl Salicylate Glucoside present in the Bark of *Betula lenta*. M. BRIDEL (*Compt. rend.*, 1924, **178**, 1310—1312).—The glucoside isolated by Schneegans and Gerock (A., 1895, i, 109) from the bark of *Betula lenta* and named gaultherin yields, not merely methyl salicylate and dextrose, but also xylose, on hydrolysis. It is, indeed, identical with the author's monotropitin (A., 1923, i, 1275), and it is suggested that the latter name be retained and gaultherin discarded. T. H. P.

Biochemical Resolution of Rutin. Formation of a New Glucide, Rutinose. C. CHARAUX (*Compt. rend.*, 1924, **178**, 1312—1314).—The formation of rhamninose by the action of rhamninase on rutin (cf. Ter Meulen, A., 1911, i, 391) is questioned. From the defatted, dehusked seeds of *Rhamnus utilis* the author has obtained, by maceration with water followed by precipitation with alcohol, an enzyme which hydrolyses rutin with formation of quercetin and of a new sugar, termed *rutinose*. The latter is hygroscopic and has no sharp melting point, softening at about 140° and becoming liquid and darkening at 189—192°. It reduces Fehling's solution and exhibits mutarotation in aqueous, but not in alcoholic, solution. When hydrolysed by means of dilute hydrochloric acid, it yields rhamnose (1 mol.) and dextrose (1 mol.).

The same enzyme hydrolyses: robinin, giving a glucide composed of rhamnose (2 mols.) and galactose (1 mol.); a yellow glucoside

obtained from the flowers of *Spiræa ulmaria*, yielding a glucide (apparently different from rutinose), xanthorhamnin, primeverin, baptisin, helicin, and amygdalin. It is without action on *iso*-hesperidin.
T. H. P.

Plant Pigments. I. Yellow Colouring Matter of the Acacias. J. M. PETRIE (*Proc. Linnean Soc. N.S. Wales*, 1923, **48**, 356—367).—The soluble colouring matter of the yellow inflorescence of *Acacia discolor*, *A. linifolia*, *A. decurrens* (var. *mollis*), and *A. longifolia* is a rhamnose glucoside of kaempferol, fine, hair-like crystals. No free flavinol was found; the yellow flavinol (0·06%) on reduction with nascent hydrogen gave a red solution resembling that of the natural anthocyanilidine. Carotene and xanthophyll (0·14—0·3%) were present as plastid pigments. The tannins were composed of phloroglucinol, protocatechuic and gallic acids, and on hydrolysis gave red phlobaphen anhydrides.
CHEMICAL ABSTRACTS.

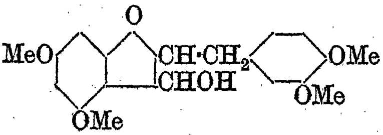
Insecticides. I. Isolation and Constitution of the Active Constituent of Dalmatian Insect Powder. H. STAUDINGER and L. RUZICKA.—(See i, 700.)

Electrolytic Reduction of Carbonyl Derivatives. H. HIBBERT and R. R. READ.—(See i, 613.)

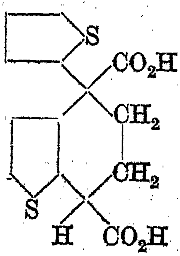
Humic Acids. H. TROPSCH and A. SCHELLENBERG.—(See i, 619—621.)

Degradation Product of Brazilin obtained by Schall and Dralle. P. PFEIFFER (*Ber.*, 1924, **57**, [*B*], 738; cf. this vol., i, **413**, **537**).—Tschitschibabin and Nikitin had already prepared 3-methoxychromanone from the corresponding methoxyphenoxypropionic acid.
F. A. M.

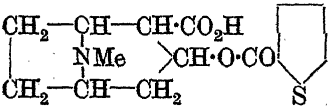
Tannins and Similar Substances. XV. A New Degradation of Catechin. K. FREUDENBERG, L. ORTHNER, and H. FIKENTSCHER (*Annalen*, 1924, **436**, 286—298).—The series of reactions which led to the elucidation of the structure of diacetonedextrose and -lævulose (A., 1923, i, 652) has now been applied to the case of catechin. By the action of toluene-*p*-sulphonyl chloride on tetramethyl-*d*-catechin in pyridine solution, the *p*-toluenesulphonic ester, $C_{26}H_{28}O_8S$, m. p. 87—88°, is obtained, which with hydrazine yields: (1) the primary *hydrazide*, $C_{19}H_{24}O_5N_2$ ($+H_2O$, lost *in vacuo* at 65°), m. p. 101—104°, this substance being oxidised by potassium permanganate to give a little tetramethyl-*d*-catechin, m. p. 145°. (2) The highly unstable 3-*mp*-dimethoxyphenylpyrazoline, m. p. 144—145° (*picrolonate*, m. p. 207—208°), which on oxidation with potassium permanganate yields veratric acid, demethylation with hydriodic acid giving a *substance* having m. p. about 240°. (3) Phloroglucinol dimethyl ether, identified as the dibromotrimethyl ether and as *phenacylphloroglucinol dimethyl ether*, m. p. 89°. The condensation of veratraldehyde with acetaldehyde in alcoholic potassium hydroxide gives 3 : 4-*dimethoxycinnamaldehyde*, bright yellow, rhombic crystals, m. p. 82—83°, which with hydrazine affords the above 3-*mp*-dimethoxyphenylpyrazoline. The constitution favoured for tetramethylcatechin is that represented by the annexed formula, although two other possibilities are discussed. Dichloropentacetyl-*d*-catechin (*Ber.*, 1880, **13**, 694), when treated with methyl sulphate and methyl-alcoholic potassium hydroxide, affords *dichlorotetramethyl*-d-*catechin*, long, white needles, m. p. 156—157°. R. B.



Thiophen Series. XVIII. Synthesis of the "Thiophen-isologue" of Atropine. W. Steinkopf and A. Wolfram (*Annalen*, 1924, **437**, 22—36).—Ethyl thienyl-2-glyoxylate (b. p. 138—140°/13 mm.) was prepared by treating thiophen with ethyl oxalic chloride (cf. Scholl and Egerer, A., 1913, i, 588) in presence of aluminium chloride. With magnesium methyl bromide, it gives *ethyl α-hydroxy-α-2-thienylpropionate*, an oil, b. p. 134—135°/13 mm., readily hydrolysed by barium hydroxide to the corresponding *acid*, needles, m. p. 107°. When alkali hydroxide is used as hydrolysing agent, side reactions take place and an amorphous product resembling that described below is obtained. It was found impossible to isolate α-2-thienylacrylic acid; the above hydroxy-acid, treated with acid in various ways, gives solely a mixture of two *isomerides*, one amorphous (decomp. 95°), the other crystalline, m. p. 216°. The latter, termed di-α-thienylacrylic acid, has properties which suggest that it has the annexed formula. The amorphous substance was also obtained as a by-product in the preparation of β-*chloro-α-2-thienylpropionic acid*, which was eventually isolated by treating α-hydroxy-α-2-thienylpropionic acid with hydrogen chloride in ether solution at −40° to −30°. It forms rhombs, m. p. 77°. Hydrolysed with calcium carbonate, it gives β-*hydroxy-α-2-thienylpropionic acid*, prisms, m. p. 95·5—96°, the *acetyl* derivative of which is oily, and when treated with thionyl chloride yields β-*acetoxy-α-2-thienylpropionyl chloride*, also an oil. Tropine with the latter compound in benzene solution affords β-*hydroxy-α-2-thienylpropionyltropine*, "*thiophen-cocaine*" (*chloroplatinate*, decomp. 240—241°, and *picrate*, m. p. about 142°, described). The quantity obtained was insufficient for pharmacological tests. W. A. S.

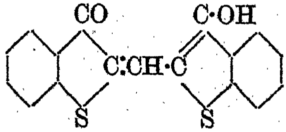


Thiophen Series. XVII. Preparation of the "Thiophen-isologue" of Cocaine. W. Steinkopf and W. Ohse (*Annalen*, 1924, **437**, 14—22).—"Thiophen-cocaine" was obtained by methylating the product of interaction of ecgonine and thiophen-2-carboxylic anhydride. Thiophen-2-carboxylic acid is best prepared (yield: 96%) from 2-bromothiophen (Steinkopf, A., 1923, i, 124) by the Grignard reaction (cf. Schlenk and Ochs, A., 1915, i, 579). The best yield (62%) of 2-cyanothiophen, the intermediate in an alternative preparation of the acid, was obtained when cyanogen chloride was used; the bromide, iodide, and cyanogen itself gave poor yields (cf. Karrer and others, A., 1919, i, 591). Thiophen-2-carboxylic acid heated with acetic anhydride yields the *anhydride*, needles, m. p. 62° b. p. 218—220°/15 mm., rapidly reacting in warm aqueous suspension with ecgonine to give *thiophen-2-carboxyecgonine* (annexed formula), which sinters at 94°, solidifies and melts at 186°, and has $[\alpha]_D^{17\cdot5}$ —19·07° to —17·49° in chloroform. Its *hydrochloride* has m. p. 225° (decomp.). The *methyl* ester, viz. "*thiophen-cocaine*," has m. p. 107°; its *hydrochloride*, m. p. 184·5°, the *picrate*, yellow needles, m. p. 175°, and *chloroplatinate* are described. Pharmacologically the substance closely resembles cocaine but appears to be less toxic. W. A. S.

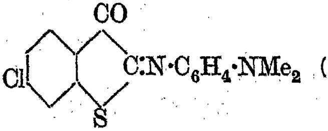


Fission of Indigoid Dyes by Alkalis. P. FRIEDLÄNDER and L. SANDER (*Ber.*, 1924, 57, [*B*], 648—652; cf. A., 1922, i, 764).—Thioindigotin when heated with 45% potassium hydroxide and a little alcohol is converted into oxythionaphthen, thionaphthenquinone, and a little of the known substance (I). 6 : 6′-Dichlorothioindigotin is much more resistant to the above treatment and affords 6-chloro-3-oxy(1)thionaphthen (colourless needles, m. p. 143°) (cf. Ruppel, *Dissert.* Darmstadt, 1921), and *6-chlorothionaphthenquinone.* The latter (orange needles, m. p. 134°) was also prepared by condensing the chloro-oxythionaphthen with *p*-nitrosodimethylaniline, the resulting *6-chlorothionaphthenquinone*-p-*dimethylamino-2-anil* (II) (dark green, metallic prisms, m. p. 190°) being hydrolysed by hydrochloric acid. 6 : 6′-Dichloro-4 : 4′-dimethylthioindigotin, on treatment with alkali, gives only a trace of 6-*chloro*-4-*methylthionaphthenquinone*, orange needles, m. p. 132°, which was also prepared from the *anil*, m. p. 123·5°. *iso*Indigotin has been prepared by an improved method (due to B. Homolka) from isatin and an aqueous solution of sodium sulphide and ammonia. It is converted by hot aqueous-alcoholic sodium hydroxide into *hydroxydihydroisoindigotin*, (III), colourless leaflets or needles, m. p. 250—280° (decomp.) (converted by hot acetic anhydride into diacetyl*iso*indigotin), and *quinindolinecarboxylic acid* (IV), yellow needles (*sodium* salt, $C_{16}H_9O_2N_2Na,3H_2O$, yellow needles), a little isatin and other substances also being formed. The acid, when heated at 300°, affords quinindoline (cf. Gabriel and Eschenbach, A.,

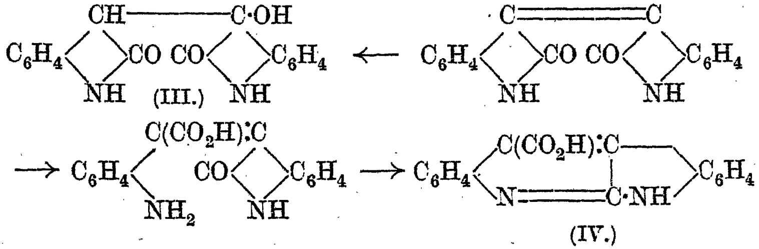
(I.)



(II.)



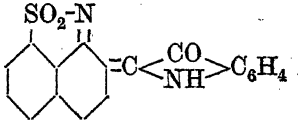
1898, i, 199). The decomposition by alkali probably occurs as shown below:

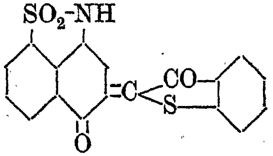


F. A. M.

Indigoid Dyes. P. FRIEDLÄNDER and L. SANDER (*Ber.*, 1924, **57**, [*B*], 637—648).—The following new indigoid dyes are described: the *dye* (I) from naphthasultam and isatinanilide by condensation in presence of acetic anhydride, forms deep bluish-violet needles with red iridescence which give a yellow solution in alkali.

(I.)





(II.)

The condensation of 3-oxy(1)thionaphthen with naphthasultamquinone in acetic acid yields a *dye* (II) which forms purple-black needles. No dye could be obtained on attempting to condense isatinanilide with the *p*-tolylsulphamide of α-naphthylamine, although the latter couples with diazo compounds in alkaline solutions. A re-examination of the "2-dihydronaphthalene-2′-indoleindigo" described by Herzog and Kreidl (A., 1923, i, 61) showed that their product was probably an impure "2-naphthalene-2-indoleindigo." The substance described by Herzog and Kreidl as 1-keto-2 : 3′-oxy-2′-thionaphthentetrahydronaphthalene may, however, have the structure ascribed to it, although analysis alone is insufficient to determine the presence or absence of the two hydrogen atoms; on warming with concentrated aqueous-alcoholic sodium hydroxide, it forms a yellow solution from which acetic acid precipitates a yellow, amorphous *additive* compound with water possibly $C_{10}H_8O{:}C(OH){\cdot}CO{\cdot}C_6H_4{\cdot}SH$. Above 100°, the dye is re-formed; the hydrated compound behaves like an enol and like a mercaptan. 6-*Ethoxythionaphthenquinone*-2-*anil* was prepared from 6-ethoxythionaphthen and nitrosobenzene as yellow needles, m. p. 118—119°. It condensed with α-ketotetrahydronaphthalene in acetic anhydride to give the brownish-red dye, "3 : 4-*dihydro*-2-*naphthalene*-6′-*ethoxy*-2′-*thionaphthenindigo*." 2-*Chloro*-1 : 4 *naphthaquinone monoanil* was obtained by condensing 2-chloro-α-naphthol with nitrosobenzene in presence of ammonia as fiery red needles, m. p. 112°; it was not possible to obtain an indigoid dye from it by condensation with oxythionaphthen; by using sodium hydroxide in the above condensation in place of ammonia, the product was almost entirely Euler's anilinonaphthaquinone-monoanil, the chlorine atom being removed. The following *acyl* derivatives of indigoid dyes were also prepared: "N-*Acetyl-2-indole-2′-thionaphthenindigo*," from the corresponding indigoid dye, acetic anhydride, and acetyl chloride, forms light red needles; *di*(N-*acetyl*)iso*indigotin*, obtained similarly from *iso*indigotin, forms brick-red crystals. N : N′-*bis*(*chloroacetyl*)*indigotin* was obtained from indigotin and chloroacetyl chloride as ruby-red, quadratic, double pyramids; it is sensitive to water-vapour and gradually becomes coated with indigotin; "4-*acetylamino-2-naphthalene-2′-indoleindigo*" is a violet-blue product, and "4-*acetylamino-2-naphthalene-2′-thionaphthenindigo*" reddish-violet. Treatment of indigotin with oxalyl chloride in boiling nitrobenzene afforded *oxalylindigotin* as yellow needles, m. p. above 200°. It is extremely easily hydrolysed by dilute alkali with regeneration of indigotin and is sulphonated by warm fuming acid (20% SO_3). These observations confirm Friedländer's view (A., 1922, i, 765) that saturation of the nitrogen atoms in indigoid dyes leads to lightening of the colour. F. A. M.

Derivatives of 3-Oxy(1)thionaphthen. L. R. HART and S. SMILES (*J. Chem. Soc.*, 1924, **125**, 876—881).—*o*-Thiolbenzoic acid condenses with compounds containing a labile methylene group to give 3-oxythionaphthen derivatives (cf. T., 1923, **123**, 2907), but in no case are 2 : 2-disubstituted derivatives formed; one of the groups originally attached to the methylene group is always displaced, and if this cannot happen the reaction does not take place. *o*-Thiolbenzoic acid and oxalacetic, acetylpyruvic, or pyruvic acid react in sulphuric acid solution to give 3-*oxy*(1)*thionaphthen-2-glyoxylic acid*,  $C_8H_4{<}\genfrac{}{}{0pt}{}{CO}{S}{>}CH\cdot CO\cdot CO_2H,H_2O$, m. p. 174° when anhydrous. The *calcium* salt is described. The *phenylhydrazone* forms orange needles, m. p. 187°, and the *anil* yellow plates, m. p. 190°. The o-*amino-anil* forms yellow prisms (converted into the following compound before melting). When *o*-phenylenediamine and the acid were mixed in boiling acetic acid, "2-*thionaphthen-2-quinoxalineindigo*,"  $C_6H_4{<}\genfrac{}{}{0pt}{}{CO}{S}{>}C{:}C{<}\genfrac{}{}{0pt}{}{CO-NH}{NH\cdot C_6H_4}$, was readily formed as a red, crystalline powder not melting below 315°. 2-*Benzoyl-3-oxy*(1)*thionaphthen* was produced by condensation of *o*-thiolbenzoic acid and benzoylacetone; it forms orange or pale yellow needles, m. p. 116—117°. Its *phenylhydrazone* crystallises in orange plates, m. p. 160°. Its acetyl derivative, 2-*benzoyl-3-acetoxy*(1)*thionaphthen*, forms needles, m. p. 106°. 2-*Acetyl-3-benzoyloxy*(1)*thionaphthen*, formed by benzoylating 2-acetyl-3-oxythionaphthen, has m. p. 145°. The disinclination to form 2 : 2-disubstituted derivatives is again shown here. 2-*Benzoyl-3-benzoyloxy*(1)*thionaphthen* crystallises in plates, m. p. 113°.

W. A. S.

Constitution of Evodiamine and Rutæcarpine. Y. Asahina (*J. Pharm. Soc. Japan*, 1924, No. 503, 1—7; cf. Asahina and Mayeda, A., 1921, i, 48).—Indole-β-ethylamine (3-aminoethylindole) is obtained by the decomposition of evodiamine. The constitutions of evodiamine and rutæcarpine are, therefore, as stated by Kermack, Perkin, and Robinson (T., 1921, **119**, 1615).

K. K.

Methylation of Tertiary Amines and Alkaloids by means of Methyl Sulphonic Esters derived from Phenols. L. J. Simon and M. Frèrejacque (*Compt. rend.*, 1924, **178**, 945—947).—When treated with methyl iodide or sulphate or with one of various sulphonic esters derived from aromatic hydrocarbons, hexamethylenetetramine yields the salt of a quaternary methylated base, one methyl group being fixed by a tertiary nitrogen atom: $C_6H_{12}N_4+R\cdot OMe=C_6H_{12}N_3(NMe)\cdot OR\longrightarrow C_6H_{12}N_3\cdot NMe\cdot OH$. This reaction is effected very readily and completely by the methyl sulphonates derived from phenols (A., 1923, i, 462, 1098), giving the phenolsulphonates of the same base. The reaction is best carried out in chloroform solution and, even in the cold, is extremely sensitive, 0·02 g. of hexamethylenetetramine rapidly yielding the characteristic crystalline compounds. The *compounds* obtained, with their approximate decomposition temperatures, are as follows: $OH\cdot C_6H_4\cdot SO_3Me$ [1 : 4], 225°; $OH\cdot C_6H_3Me\cdot SO_3Me$ [2 : 1 : 5], 134°; $OH\cdot C_6H_3Me\cdot SO_3Me$ [OH : Me=1 : 4], 175°; $OMe\cdot C_6H_4\cdot SO_3Me$ [1 : 4], 195°; $OMe\cdot C_6H_3Me\cdot SO_3Me$ [2 : 1 : 5], 190°; $OMe\cdot C_6H_3Me\cdot SO_3Me$ [OMe : Me=1 : 4], 215°; $OH\cdot C_6H_3(CO_2Me)\cdot SO_3Me$ [OH : CO_2Me=2 : 1], 230°. These salts yield the corresponding *picrates* when treated with picric acid in aqueous solution.

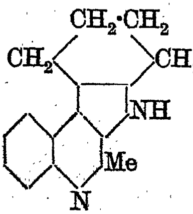
Compounds of similar type are obtainable from antipyrine, pyramidone, dimethylaniline, and pyridine, a solvent other than chloroform being sometimes necessary. The products obtained from antipyrine by means of the methyl sulphonates of methyl salicylate and anisole have m. p. 135° and 96°, respectively. The salt formed from pyramidone and methyl anisolesulphonate has m. p. 162°, and that from pyramidone and dimethyl sulphosalicylate, m. p. 97°. The reaction is applicable also to the alkaloids. T. H. P.

Kinetics of Catalytic Dehydrogenation. II. N. Zelinsky and G. Pawlow (*Ber.*, 1924, **57**, [*B*], 669—671; cf. A., 1923, i, 767).—Palladium is a much more active catalyst than platinum in effecting the dehydrogenation of piperidine, which, with the first metal, only follows a normal course at temperatures below 250°; at higher temperatures the catalyst becomes partly inactivated owing to subsidiary reactions. The phenomenon is due to the chemical nature of piperidine, since the dehydrogenation of *cyclo*hexane (*loc. cit.*) occurs normally within much wider limits of temperature. With piperidine, as with *cyclo*hexane, dehydrogenation commences at about 150°; between 150° and 200°, piperidine is much more energetically dehydrogenated by palladium than is *cyclo*hexane.

H. W.

Spectrochemistry of Heterocyclic Nitrogen Compounds. K. VON AUWERS and W. KOHLHAAS (*Annalen*, 1924, **437**, 36—63).—Densities and refractivities for the α, He, β, and γ lines at various temperatures are recorded for pyrrole, 1-methylpyrrole, 2 : 4- and 2 : 5-dimethylpyrroles, and 2 : 3 : 5-trimethylpyrrole; for 26 pyrazole compounds, including 3 : 5-*dimethylpyrazole*, m. p. 58° (*picrate*, m. p. 153°); 4-*chloro*-1-*phenyl*-3 : 5-*dimethylpyrazole*, b. p. 162—165°/10—11 mm.; for 20 derivatives of tetrahydroindazole (cf. this vol., i, 325) and for 21 of indazole itself (cf. also A., 1921, ii, 73; 1922, ii, 98). W. A. S.

Mechanism of E. Fischer's Synthesis of Indoles. Application of the Method to the Preparation of a Pyrindole Derivative. G. M. ROBINSON and R. ROBINSON (*J. Chem. Soc.*, 1924, **125**, 827—840).—Largely polemical against Hollins (A., 1922, i, 863). Reddelien's explanation of the reaction (A., 1912, i, 263), involving as it does an oxidation and scission of the hydrazone as an intermediate stage, is untenable because, in the first place, tetrahydrocarbazole may be obtained from *cyclo*hexanonephenylhydrazone even when stannous chloride is present in the reaction mixture, and, secondly, 2-methylindole, or nitrotetrahydrocarbazole, is produced normally even when *p*-toluidine, or aniline, respectively, is added to supply, on Reddelien's hypothesis, an alternative base. Further, *N*-methyltetrahydrocarbazole is the sole product of the action of hot acetic acid and aniline (20 mols.) on *cyclo*hexanonephenylmethylhydrazone. Thus the authors' original theory (A., 1918, i, 448) is substantiated. The same general method has been applied to the synthesis of a pyrindole derivative (cf. Fargher and Furness, A., 1915, i, 842). 3-*Hydrazinoquinaldine*, prepared by reducing diazotised 3-aminoquinaldine, first with sodium hydrogen sulphite, then with the hyposulphite, forms pale yellow needles, m. p. 169°. *Benzaldehydequinaldyl*-3-*hydrazone* crystallises in yellow plates, m. p. 202°, its *hydrochloride* in needles, m. p. 261°. *cyclo*Hexanonequinaldyl-3-hydrazone has m. p. about 100° in the crude (colourless) condition, but when recrystallised is converted into an orange *dioxide*(?), needles, m. p. 131° (decomp.). This yields 3-quinaldineazo-β-naphthol when fused with β-naphthol and generally behaves remarkably like quinaldine-3-diazo-4-oxide (Conrad and Limpach, A., 1888, 1109). By treating quinaldylhydrazine with a large excess of *cyclo*hexanone, 3-*methylbenzo*-(5 : 6-)9 : 10 : 11 : 12-*tetrahydro*-4-*carboline* (annexed formula) was obtained. This substance crystallises from benzene in needles, m. p. 198°, containing benzene (1 mol.), which is lost at 140—150°, the substance then melting at 226°. Its *methosulphate* has m. p. 225°; treated with potassium hydroxide, it yields 3 : 4-*dimethylbenzo*-(5 : 6-)9 : 10 : 11 : 12-*tetrahydro*-4-*isocarboline*, yellow needles, m. p. 120° (decomp.). *cyclo*Hexanone interacts with hydrazine itself to form an azine (cf. Mailhe, A., 1922, i, 332), which with zinc chloride forms a *compound*,



$C_{12}H_{20}N_2,HCl,ZnCl_2$, colourless prisms, m. p. 271—272°. Certain analytical figures relating to the compound obtained from cotarnine and 6-nitropiperonal are corrected (cf. T., 1914, **105**, 1468).

W. A. S.

Intramolecular Condensation Reactions of Aminoaldehydes and Aminoacetals. II. Course of the Reaction in the Formation of Dihydroquinoline and a New Preparation of Indole Derivatives. C. Räth (*Ber.*, 1924, **57**, [*B*], 715—718; cf. this vol., i, 555).—When *o*-aminopropylbenzene is heated with chloroacetal at 250° the expected *4-ethyl*-1 : *2-dihydroquinoline*, a pale yellow oil (b. p. 125—135°) with slightly tarry odour (*hydrochloride*, pinkish, hygroscopic, and amorphous), is formed together with *3-ethoxy-4-ethyl*-1 : 2 : 3 : *4-tetrahydroquinoline*, a yellow, viscous oil (b. p. 180—185°/21 mm., or 175—185°/17 mm.). β-Chloropropionacetal and aniline when heated together at 250° give a little dihydroquinoline and (mainly) *4-ethoxytetrahydroquinoline*, a yellowish-brown, viscous oil (b. p. 264—270°), which darkens in air (*picrate*, fine, yellow needles). *3-Ethoxy*-1-*ethyl*-2 : *3-dihydroindole* (*hydrochloride*, amorphous), a thick, yellow liquid, b. p. 153—163°/11 mm., is obtained from ethylaniline and bromoacetal, although the chief product in this case is 1-ethylindole.

F. A. M.

Synthesis of 2 : 4 : 7- and 2 : 4 : 8-Trimethylquinolines. S. Yamaguchi (*J. Pharm. Soc. Japan*, 1924, No. 503, 8—33).—The author has synthesised 2 : 4 : 7- and 2 : 4 : 8-trimethylquinolines and their salts, from acetone, paraldehyde, and *m*- and *o*-toluidines, respectively. Generally speaking, 2 : 4 : 6- and 2 : 4 : 7- but not 2 : 4 : 8-derivatives have a large affinity for water and for methyl iodide.

2 : 4 : 8-Trimethylquinoline is a white solid, m. p. 42°, b. p. 269—270°, and gives the following salts: *hydrochloride*, m. p. 238°; *hydrobromide*, m. p. 251° (decomp.); *hydriodide*, m. p. 224°; *chloroaurate*, m. p. 191°; *chloroplatinate*, m. p. 275° (decomp.); *mercurichloride*, m. p. 234°; *zincichloride*, m. p. 295—296° (decomp.); *hydrogen sulphate*, m. p. 263°; *dichromate*, decomp. at about 180°; *picrate*, m. p. 193°; methiodide, m. p. 229° (decomp.).

2 : 4 : 7-Trimethylquinoline is a colourless, oily liquid, b. p. 280—281°, d^{20} 1·0337, n_D^{24} 1·59732. On exposure to air, or when crystallised from water, it forms a crystalline *hydrate*, m. p. 48°. The following salts are described: *hydrochloride*, sublimes at about 310°; hydrobromide, m. p. 351° (decomp.); *hydriodide*, m. p. 320° (decomp.); *chloroaurate*, m. p. 152°; *chloroplatinate*, m. p. 272° (decomp.); *mercurichloride*, m. p. 244°; *zincichloride*, m. p. 258°; *hydrogen sulphate*, m. p. 223°; *dichromate*, decomp. at about 179—180°; *picrate*, decomp. 232°; methiodide, subliming at about 322°.

K. K.

Relations between Chemical Constitution and Taste. (Miss) C. Riccomanni (*Atti R. Accad. Lincei*, 1924, [v], **33**, i, 145—148).—1 : 4-Di-δ-phenyl-Δ^β-pentenoylpiperazine, prepared by heating piperazine at 100—105° with δ-phenyl-Δ^β-pentenoic acid (cf.

Staudinger and Schneider, A., 1923, i, 361; Staudinger and Müller, A., 1923, i, 363), is obtained as a dense, brownish-yellow oil with a pungent, aromatic taste, yields a yellow *picrate*, m. p. 245°, and when mixed in the proportion of 2% with flour produces a taste similar to, although less intense than, that of pepper. Evidently piperidine is not necessary for obtaining the flavour of pepper.

When added in the proportion of 1% to flour, styryl methyl ketone exhibits a markedly sharp taste (cf. Nomura, T., 1917, i, 769; A., 1918, i, 446; Nomura and Nozawa, A., 1918, i, 438); cinnamylidenemethyl methyl ketone has an intense, biting taste which appears after a time; benzyl methyl ketone has also an acute taste and acetophenone a pungent taste which disappears almost immediately. With compounds which lack the phenyl group or which contain a partly hydrogenated aromatic ring, such as ionone, the acute taste disappears almost completely.

2-Acetylpyrrole, 2-pyrryl styryl ketone, and the product of the condensation of cinnamaldehyde with 2-acetylpyrrole,

$$C_4H_4N{\cdot}CO{\cdot}CH{:}CH{\cdot}CH{:}CHPh,$$

have sweet, and in no way pungent, tastes. T. H. P.

Preparation of New Salts of CC-Disubstituted Barbituric Acids. E. LAYRAUD (Brit. Pat. 202660).—New salts are obtained by mixing hot aqueous solutions of *as*-CC-disubstituted barbituric acids and piperazine. *Piperazine ethylbutylbarbiturate* melts at about 150—155°. The piperazine salts (acid : base=1 : 1 mol.) afford stable aqueous solutions. *Salts* are also obtained by treating ethyl*iso*butyl-, ethyl*iso*amyl-, propylbutyl-, propyl*iso*butyl-, and propyl*iso*amyl-barbituric acids with either an organic base, other than piperazine, or an inorganic base, other than sodium.

W. T. K. B.

Synthetic Hypnotics of the Barbituric Acid Series. A. W. DOX (*J. Amer. Pharm. Assoc.*, 1923, **12**, 602—609).—A consideration of the nature of the group producing hypnotic effect. In the veronal class, the group $\cdot CR_2{\cdot}CO{\cdot}NH{\cdot}CO\cdot$ is a "hypnophore." Macht's "specific benzyl effect" is simply a higher alcohol effect. To manifest hypnotic action without undesirable after-effects, the two 5-alkyl groups of the pyrimidine ring should together contain between 4 and 8 carbon atoms; at least one such group must be of open-chain form. The benzyl group is undesirable, the carbamide group may not be replaced by the amidine group, and the molecular weight should not exceed about 250. CHEMICAL ABSTRACTS.

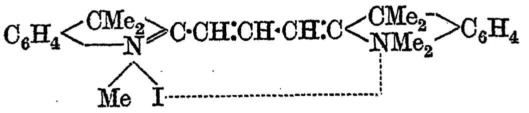
Hypnotic and Analgesic Compounds from Dimethylaminophenyldimethylpyrazolone and Dialkylbarbituric Acids. E. H. VOLWILER (U.S. Pat. 1478463).—Yellow or orange-yellow, crystalline compounds, m. p. 94·5—96·5°, 88—90°, 84—86°, and 90—94°, are produced from dibutyl-, ethylbutyl-, ethyl*sec.*butyl-, and ethyl*iso*amyl-barbituric acids, respectively. *Ethyl*sec.*butylbarbituric acid* is obtained by condensing ethyl ethyl*sec.*butylmalonate (b. p. 133°/48 mm.) with carbamide in the presence of sodium ethoxide. CHEMICAL ABSTRACTS.

Mother Substance of Indian-yellow. F. MAYER (*Arch. Exp. Path. Pharm.*, 1924, **101**, 383—385).—The formulæ proposed by Wiechowski (A., 1923, i, 591) for mangin and euxanthone are at variance with the accepted conclusions of Fischer and Piloty (A., 1891, i, 677) and other workers; they are therefore to be regarded as erroneous. W. O. K.

Constitution of Pyrazoles, Indazoles, and Anthranils. K. VON AUWERS (*Annalen*, 1924, **437**, 63—86).—A discussion of the bearing of data previously obtained (see i, 666) on the constitution of these compounds. To assist in calculating atomic refractivities for singly-linked or doubly-linked nitrogen, refractivity measurements were made on eleven substituted hydrazines, whilst the constants for five more indazole derivatives, anthranil itself, and three substituted anthranils are also recorded. The author's conclusion is that none of the indazole compounds contains a 3-membered ring structure and that the 1- and 2-derivatives differ only in the arrangement of the double bonds. Anthranil and related compounds should be formulated as analogous to indazole, not as internal amides. W. A. S.

Sulphonation of Glyoxalines. II. R. FORSYTH, J. A. MOORE, and F. L. PYMAN (*J. Chem. Soc.*, 1924, **125**, 919—923).—Attempts to remove the methyl group from 2-methylglyoxaline-4-sulphonic acid so as to determine the constitution of glyoxalinesulphonic acid (T., 1920, **117**, 1429) failed. Oxidising agents either did not act or completely disrupted the molecule. A benzylidene compound was not formed. When glyoxaline is treated with 70% oleum at 160° for 36 hours the product contains 15% of a *disulphonic acid*. 2-Methylglyoxaline, similarly treated for 3—6 hours, gives 2-*methylglyoxaline*-4-*sulphonic acid*, $C_4H_5N_2\cdot SO_3H,H_2O$, prisms, m. p. (decomp.) about 279° when anhydrous. The *ammonium*, *barium*, and *sodium* salts are described. In some experiments, a small proportion (up to 17%) of the 4 : 5-*disulphonic acid* was produced. This forms needles containing $1\cdot 5H_2O$ and has m. p. 280°; its *barium* salt is described. Neither glyoxalinesulphonic acid nor methylglyoxalinesulphonic acid afforded esters or chlorides. Partial hydrolysis took place when they were heated at 170° with concentrated hydrochloric acid. Treated with bromine (1 mol.) in aqueous solution, glyoxalinesulphonic acid gives ammonium bromide, oxalic acid, and 2 : 4 : 5-tribromoglyoxaline, 65% of the acid being recovered unchanged; methylglyoxalinesulphonic acid behaves similarly, yielding a little 4 : 5-dibromo-2-methylglyoxaline and 4-bromo-2-methylglyoxaline-5-sulphonic acid (cf. Light and Pyman, T., 1922, **121**, 2626). W. A. S.

Indoleninocyanines [Indocyanines]. W. KÖNIG [with E. WAGNER] (*Ber.*, 1924, **57**, [*B*], 685—692; cf. A., 1923, i, 1188). —1 : 2 : 3 : 3-Tetramethylindolenium iodide is converted by ethyl orthoformate in boiling acetic anhydride solution into 1 : 3 : 3 : 1′ : 3′ : 3′-*hexamethyl*strepto*monovinylene*-2 : 2′-*indocyanine iodide* (annexed formula), golden needles, m. p. about 229° (decomp.).



$$C_6H_4{<}\genfrac{}{}{0pt}{}{CMe_2}{N}{>}C\cdot CH{:}CH\cdot CH{:}C{<}\genfrac{}{}{0pt}{}{CMe_2}{NMe_2}{>}C_6H_4 \quad \overset{N}{\genfrac{}{}{0pt}{}{\diagup\ \diagdown}{Me\quad I}}$$

The corresponding *bromide*, m. p. 250° (decomp.), *chloride*, decomp. 250°, *perchlorate*, m. p. 245° (decomp.), and *picrate*, m. p. 205°, are described. The new dye is remarkable among quinocyanines on account of its relatively great stability towards mineral acids and light. It is converted by a very large excess of sodium hydroxide into the corresponding pale yellow *ψ-base*, m. p. about 96° (decomp.), which when suspended in water passes into equilibrium with the red onium base. 5-*Chloro*-1 : 2 : 3 : 3-*tetramethylindolenium iodide*, pale yellow needles, m. p. 198°, prepared by fusing acetone-*p*-chlorophenylhydrazone with zinc chloride, is converted in a similar manner into 5 : 5′-*dichloro*-1 : 3 : 3 : 1′ : 3′ : 3′-*hexamethyl*strepto*monovinylene*-2 : 2′-*indocyanine iodide*, needles, m. p. 265°; the corresponding *carbinol base*, a pale yellow, amorphous substance, has m. p. about 130° (decomp.).

H. W.

Preparation of Diaminodiaryldialkylmethanes. FARBW. VORM. MEISTER, LUCIUS, & BRÜNING (Brit. Pat. 204722).—Aniline, or a nuclear alkyl-substituted derivative with a free *p*-position, is caused to react, in the form of a salt in aqueous solution, with an aliphatic ketone (*e.g.*, by heating under pressure at 120—150°). pp′-*Diaminodiphenyldimethylmethane*, $CMe_2(C_6H_4\cdot NH_2)_2$, forms colourless needles, m. p. 132°. pp′-*Diaminodi*-m-*tolyldimethylmethane* (from *o*-toluidine and acetone) has m. p. 71°, and pp′-*diaminodiphenylmethylethylmethane* (from aniline and methyl ethyl ketone), m. p. 78°. These compounds are valuable as intermediates for dyes.

W. T. K. B.

Dyes derived from Carbazole and Thiodiphenylamine. S. DUTT (*J. Chem. Soc.*, 1924, **125**, 802—807).—Carbazole condenses with aldehydes and ketones in presence of concentrated sulphuric acid or zinc chloride to form triarylmethane compounds which may be oxidised to dyes. As 3-nitro-, but not 3 : 6-dinitro-, carbazole will so condense it is inferred that substitution takes place in position 3. With formaldehyde the *compound*, $CH_2(C_{12}H_8N)_2$, colourless needles, m. p. 287°, is obtained; benzaldehyde affords the *leuco*-base, $CHPh(C_{12}H_8N)_2$, needles, m. p. above 300°, which, oxidised with nitrosyl chloride in sulphuric acid solution, gives the dark green *chloride* of the dye, the colourless *carbinol base* of which is obtained by boiling with pyridine and forms needles, m. p. above 290°. Similar compounds were prepared using *p*-dimethylaminobenzaldehyde [dark violet needles; *carbinol base*, m. p. 282° (decomp.)], *m*-nitro- and *m*-chloro-benzaldehydes. When sulphonated, all these products dye unmordanted cotton in green to violet shades. Benzophenone, *pp*′-tetramethyldiaminobenzophenone, and 2 : 3 : 4-trihydroxybenzophenone yield (with phosphoryl chloride as condensing agent) *compounds* of the type, $C_{12}H_8N\cdot CPh_2Cl$. The *carbinol base* of the first named forms colourless needles, m. p. 172°, and its *chloride* violet needles, m. p. 280—285°; the remainder have m. p.

above 290°. All dye wool in violet shades and the last-named dyes chrome-mordanted textiles dark violet or black shades. Thiodiphenylamine yields analogous derivatives. With oxalic acid, a green *compound*, $C(C_{12}H_8NS)_3\cdot CO_2H$, giving a colourless *base*, $C(C_{12}H_8NS)_3\cdot OH$, m. p. 225—227°, was formed. Benzaldehyde (*carbinol base*, decomp. 200°) and *p*-dimethylaminobenzaldehyde gave compounds dyeing cotton green and grey, respectively, from a sulphide bath. *p*-Hydroxy- and *m*-nitro-benzaldehydes also condense. With benzophenone, and its 2 : 3 : 4-trihydroxy and *pp'*-tetramethyldiamino derivatives, compounds were produced which dye wool or unmordanted cotton blue or violet shades. These substances are decomposed by concentrated sulphuric acid. Thiodiphenylamine will also condense with nitrosophenols (*p*-nitrosophenol, *p*-nitroso-*m*-dimethylaminophenol, dinitrosoresorcinol, α-nitroso-β-naphthol, β-nitroso-α-naphthol), giving products which, unlike the carbazole-indophenols, will dye cotton from a hyposulphite or sulphide "vat." By fusion with sodium polysulphide at 250—300°, they yield sulphur dyes giving green, brown, or black shades. Compounds with similar properties are formed with diketones (benzil, phenanthraquinone, isatin). W. A. S.

Preparation of Acylacetyl Compounds. CHEM. FABR. GRIESHEIM-ELEKTRON (Brit. Pat. 211772).—Diacylacetyl compounds are prepared by heating, preferably in a solvent (*e.g.*, a benzene hydrocarbon, chlorobenzene, nitrobenzene, naphthalene, or a large excess of the acylacetic ester used), at least 2 mols. of an acylacetic ester with 1 mol. of a diamine of the general formula $NH_2\cdot Y\cdot NH_2$, where Y represents an aryl or substituted aryl residue, a diaryl or substituted diaryl residue, or a residue of a diaryl compound of the type $-Ar\cdot Z\cdot Ar'-$, where Ar and Ar' stand for the same or different aryl or substituted aryl residues united by a connecting link, Z, which may be $\cdot O\cdot$, $\cdot S\cdot$, $\cdot CH_2\cdot$, $\cdot CO\cdot$, $\cdot NH\cdot$, $\cdot NHCO\cdot$, $\cdot N{:}N\cdot$,  $O<\begin{matrix}N\cdot\\ |\\ N\cdot\end{matrix}$, $\cdot NH\cdot CO\cdot NH\cdot$, $\cdot O\cdot CH_2\cdot CH_2\cdot O\cdot$, or the like. The diacylacetyl compounds have a substantive character, so that they can be fixed on the cotton fibre in alkaline solution and developed with diazo compounds, giving shades which are fast to washing. Details of the preparation of several representatives are given, and the following new compounds described. *Diacetoacetyl*-p-*phenylenediamine*: slender, colourless needles, m. p. 167° (decomp.); *diacetoacetyl*-o-*tolidine*: slender, lustrous needles, m. p. 204—205° (decomp.); *diacetoacetyl*-o-*dianisidine*: feebly yellow needles, m. p. 164—165° (decomp.); *dibenzoylacetyl*-o-*tolidine*: slender, colourless, lustrous needles, m. p. 233° (decomp.); *diacetoacetyl*-4 : 4'-*diaminobenzophenone*: colourless, lustrous needles, m. p. 175—176° (decomp.); *diacetoacetyl*-4 : 4'-*diaminoazobenzene*: orange-yellow, crystalline powder, decomp. 233—234°; *diacetoacetyl*-1 : 4-*naphthylenediamine*: colourless needles, m. p. 197° (decomp.); *diacetoacetyl*-1 : 5-*naphthylenediamine*: silvery scales, m. p. 249—250° (decomp.); *diacetoacetyl*-2 : 6-*naphthylenediamine*: lustrous needles, m. p. 203—204° (decomp.); *diacetoacetyl*-o : o'-*dichloro*-

benzidine: colourless, crystalline flocks, decomp. 145—147°; *diacetoacetyl*-m : m′-*dichlorobenzidine*: colourless needles, decomp. 212°; *dibenzoylacetylbenzidine*: yellow, crystalline powder, m. p. 248° (decomp.); *diacetoacetyl*-4 : 4′-*diamino*-3 : 3′-*dichlorodiphenylmethane*: colourless, small crystals, m. p. 138—139° (decomp.); *diacetoacetyl*-4 : 4′-*diamino*-3 : 3′-*ditolylmethane*: colourless, felted needles, m. p. 143—144° (decomp.); *diacetoacetyl*-4 : 4′-*diaminoazoxybenzene*: brownish-yellow, crystalline powder, m. p. 219—220° (decomp.); *diacetoacetyl*-4 : 4′-*diamino*-3 : 3′-*azotoluene*: bright yellow powder, m. p. 215° (decomp.); *diacetoacetyl*-4 : 4′-*diaminodiphenylcarbamide*: colourless, lustrous leaflets, melting above 320°.

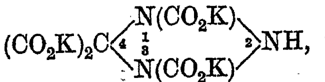
Preparation of [Azo] Dyestuffs derived from Pyrazolone and of Intermediate Products therefor. SOCIETY OF CHEMICAL INDUSTRY IN BASLE (Brit. Pat. 210669).—1-Aryl-5-pyrazolones are prepared by condensing the hydrazine derivative of an aromatic primary amine containing a sulphonamido group (*e.g.*, 3-aminobenzene-1-sulphonamide) with a suitable derivative of a β-ketonic acid (*e.g.*, ethyl acetoacetate or ethyl oxaloacetate). By coupling these pyrazolones with a diazo compound, azo dyes are obtained which are remarkable for their uniformity and purity of tint (yellow to red). More particularly is this the case with the mordant dyes obtained by coupling the new pyrazolones with diazo derivatives of *o*-aminophenol and *o*-aminonaphthol, and especially with the acid dyes containing chromium produced by treating these mordant dyes with a chroming agent (*e.g.*, chromium formate). [Cf. *B.*, 1924, 412.]
W. T. K. B.

Scission of Disulphides. Synthesis of Triazoles. E. FROMM, L. BRÜCK, R. RUNKEL, and E. MAYER (*Annalen*, 1924, **437**, 106—124).—A continuation of earlier work (cf. A., 1922, i, 377; Arndt and others, A., 1921, i, 813; 1922, i, 277, 375). 5-Amino-3-phenylamino-1 : 2 : 4-triazole has m. p. 163°, not 77° or 157°, as previously given. It forms a *benzylidene* compound, yellow needles, m. p. 225°, and a *tribenzoyl* derivative, yellow crystals, m. p. 126°. 3-Phenylamino-5-thiol-1 : 2 : 4-triazole may be oxidised to the corresponding disulphide which, treated with hot 25% sodium hydroxide, gives an equimolecular mixture (cf. *pp*′-dinitrodiphenyldisulphide, Fromm and Wittmann, A., 1908, i, 631) of the parent thioltriazole and 3-*phenylamino*-1 : 2 : 4-*triazole*, m. p. 180°, yielding a *dibenzoyl* derivative, m. p. 111—112°. 3-p-*Tolylamino-5-thiol*-1 : 2 : 4-*triazole*, from *p*-tolyldithiobiuret and hydrazine hydrate, forms colourless crystals, m. p. 271°; its *dibenzoyl* derivative, yellow leaflets, has m. p. 129°, and the *benzyl*(*thio*)*ether*, needles, m. p. 182°; this also yields a *benzoyl* derivative, scales, m. p. 133°. 5-*Amino*-3-p-*tolylamino*-1 : 2 : 4-*triazole*, the subsidiary product of the above reaction, has m. p. 178—180°, its *benzylidene* derivative, m. p. 219°. The thioltriazole, oxidised with ferric chloride, yields the *disulphide*, a yellow powder, m. p. 229°, which, treated with sodium hydroxide, gives, as above, 3-p-*tolylamino*-1 : 2 : 4-*triazole*, m. p. 199°, the *benzoyl* derivative of which forms yellow leaflets, m. p. 172°. Similar compounds containing the *o*-tolyl and *o*-anisyl radicals were prepared. *Cyano*-o-*tolylcarbamide* has m. p. 65—68°; 3-o-*tolylamino*-5-*thiol*-1 : 2 : 4-*triazole* forms needles, m. p. 263°; its *dibenzoyl* derivative has m. p. 133°, the *benzyl*(*thio*)*ether*, m. p. 161°, and this also yields a *dibenzoyl* derivative, leaflets, m. p. 125°. 5-*Amino*-3-o-*tolylamino*-1 : 2 : 4-*triazole* has m. p. 165°, and easily decomposes; its *hydrochloride* forms needles, m. p. 187°, the *benzoyl* derivative, scales, m. p. 220°. o-*Tolylthiocarbamide* has m. p. 158°; the corresponding *triazole disulphide* forms a yellow powder, m. p. 277°. o-*Anisyldithiobiuret*, m. p. 148°, treated with iodine, gives o-*anisylthiuret hydriodide*, m. p. 200°, and with benzyl chloride a *compound*, m. p. 130°. 3-o-*Anisylamino*-5-*thiol*-1 : 2 : 4-*triazole* has m. p. 280°; its *benzyl*(*thio*)*ether*, m. p. 108°; its *dibenzoyl* derivative forms yellow scales, m. p. 138°. *Aminoguanidino*-o-*anisylthiocarbamide* crystallises in needles, m. p. 134—135°, its *hydrochloride* has m. p. 178—180°, and its *benzylidene* compound forms pale yellow scales. 5-*Amino*-3-p-*phenetylamino*-1 : 2 : 4-*triazole* has m. p. 191°, its *dibenzoyl* derivative, a yellow substance, melts at 176°, and its *diacetyl* derivative at 168°. 3-p-*Phenetylamino*-5-*thiol*-1 : 2 : 4-*triazole* has m. p. 268°, its *dibenzoyl* compound, m. p. 145°, its *benzyl*(*thio*)*ether* forms needles, m. p. 172°, and yields a *benzoyl* derivative, yellow needles, m. p. 122°. The corresponding *disulphide* is an amorphous powder convertible, as above, into 3-p-*phenetylamino*-1 : 2 : 4-*triazole*, m. p. 185°. 5-*Amino*-3-*ethylphenylamino*-1 : 2 : 4-*triazole* forms scales, m. p. 198°; its *benzoyl* derivative, yellow crystals, has m. p. 188·5°, its *acetyl* derivative m. p. 157°. The corresponding 5-*thioltriazole* forms needles, m. p. 127°, *dibenzoyl* derivative, m. p. 118°, *benzyl*(*thio*)*ether*, m. p. 94°, and the *benzoyl* derivative of the latter, m. p. 65°. The by-product of the hydrazine hydrate reaction here is 3-amino-5-thiol-1 : 2 : 4-triazole (cf. Fromm and Arndt, *loc. cit.*), ethylaniline being split off. This triazole yields a 1 : 4-*dibenzoyl* derivative, m. p. 178°. The *benzoyl* derivative of 5-*benzoylamido*-3-*thiol*-1 : 2 : 4-*triazole* has m. p. above 260°.

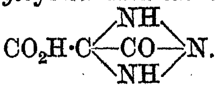
W. A. S.

Derivatives of *cyclo*Triazobutane [*cyclo*Triazomethene]. O. Diels and H. Behncke (*Ber.*, 1924, **57**, [*B*], 653—656).—The formation of additive products from azodicarboxylic ester and compounds containing an "acidic" methylene group is described (cf. A., 1923, i, 391, and previous abstracts).

Ethyl azodicarboxylate reacts with ethyl cyanoacetate in the presence of potassium acetate at 60° to form the *compound*, $CO_2Et\cdot C(CN):[N(CO_2Et)\cdot NH\cdot CO_2Et]_2$, an unstable, yellow liquid, b. p. 150—155°/0·4 mm. Ethyl malonate reacts with ethyl azodicarboxylate to yield the *substance*, $(CO_2Et)_2C[N(CO_2Et)\cdot NHCO_2Et]_2$, colourless, prismatic plates, m. p. 107°, which is remarkably stable towards acids and oxidising agents, and with methyl azodicarboxylate gives the corresponding *methyl* ester, m. p. 140—141°. Either ester is transformed by methyl-alcoholic potassium hydroxide solution into *potassium* cyclo*triazomethene*-1 : 3 : 4 : 4-*tetracarboxylate*,



$(CO_2K)_2C\left<\begin{matrix}N(CO_2K)\\ N(CO_2K)\end{matrix}\right>NH$, which could not be freed completely from potassium carbonate, but is converted by acetic acid into *potassium hydrogen* cyclo*triazomethene*-4 : 4-*dicarboxylate*, pyramids, m. p. 287° (decomp.). The latter salt with sulphuric acid affords cyclo*triazomethene*-4 : 4-*dicarboxylic acid* (long prisms, m. p. 237°, after softening and decomposing at 218°), which passes in a vacuum at 100° into 2 : 4-*carbonyl*cyclo*triazomethene*-4-*carboxylic acid*,



$$CO_2H\cdot C\left<\begin{matrix}NH\\ -CO-\\ NH\end{matrix}\right>N.$$

The monocarboxylic acid loses carbon dioxide at 218°, to give 2 : 4-*carbonyl*cyclo*triazomethene*, colourless prisms, m. p. 237°.
H. W.

Action of Pyridine on Hydrazono-acid Chlorides. C. Bülow and F. Seidel (*Ber.*, 1924, **57**, [*B*], 629—633).—The compound [m. p. 186°, not 168°, as erroneously recorded by Bülow and Neber (A., 1913, i, 999)] obtained from 2 : 4-dichlorophenylhydrazinopyruvyl chloride and pyridine is shown to have the constitution, $CH_3\cdot CO\cdot C(C_5H_4N):N\cdot NH\cdot C_6H_3Cl_2$, since the basic properties of the pyridine nitrogen atom are retained in it, as is proved by the formation of a *hydrochloride*, m. p. 168°, a *chloroaurate*, and a *chloroplatinate*. Similarly, the pentabromo derivative obtained from 4-phenylazo-3-methylisoxazolone (Hecking, *Diss.*, Tübingen, 1913) or from ethyl phenylazoacetoacetate (Memminger, *Diss.*, Tübingen, 1910) is transformed by cold pyridine into the *compound*,

$$CH_3\cdot CO\cdot CH(C_5H_4N)\cdot NBr\cdot NBr\cdot C_6H_3Br_2,$$

red needles, m. p. 162° (*hydrochloride*, m. p. 159—160°), which is converted by zinc and alcoholic hydrochloric acid into pyridine and *p*-bromoaniline. The composition $C_{15}H_{13}ON_3Br_4$ is assigned to the product of the action of pyridine on the pentabromo compound from 4-*o*-tolylazo-3-methylisoxazolone (Memminger, *loc. cit.*). The 2 : 4-dichlorophenylhydrazone of ethyl α-chloroglyoxylate is transformed by pyridine into the *substance* $C_{15}H_{14}O_2N_3Cl_3,H_2O$, yellow crystals, m. p. 142° after darkening at 130°.
H. W.

Colour of Azo Compounds and their Salts. F. Kehrmann and S. Hempel (*Ber.*, 1924, **57**, [*B*], 751; cf. A., 1917, i, 593).—An acknowledgment of the priority of V. Piccard (A., 1913, i, 895), regarding the colours of 4 : 4′-diaminoazobenzene, its tetramethyl derivative, and their salts in different solvents.
F. A. M.

Indoleazobenzene. W. Madelung (*Ber.*, 1924, **57**, [*B*], 751; cf. this vol., i, 423).—An acknowledgment of the preparation by Pieroni [*Atti R. Accad. Lincei*, 1921, (v), **30**, i, 267] of indoleazobenzene.
F. A. M.

Preparation of Acylacetyl Compounds. Chem. Fabr. Griesheim-Elektron (Brit. Pat. 211814).—Acylacetyl compounds are obtained, under exactly similar conditions to those required in the preparation of diacylacetyl compounds (cf. Chem. Fabr.

Griesheim-Elektron, this vol., i, 671), by the interaction of an acylacetic ester and a monoamine of the general formula $NH_2{\cdot}R{\cdot}X{\cdot}R'$, where R represents an aryl residue, R′ the same or a different aryl residue or a heterocyclic or acyclic residue containing a methylene group capable of coupling with diazo compounds, X an azo or azoxy group, or the residue of a 5-membered heterocyclic nucleus. The products resemble the diacylacetyl compounds in their substantive character. The following compounds are described. *Acetoacetyldehydrothiotoluidine*: colourless, crystalline powder, m. p. 170—172° (decomp.); *acetoacetylbenzeneazo*-1-*naphthylamine*: slender, orange needles, m. p. 154—155° (decomp.); *acetoacetyl*-4-*aminoazobenzene*: yellowish-orange, finely-crystallised powder, m. p. 130—131°; *acetoacetyl*-4′-*aminobenzeneazo*-1-*phenyl*-3-*methyl*-5-*pyrazolone*: slender, orange-yellow, lustrous needles, decomp. 208°; *acetoacetyl*-o-*aminoazotoluene*: slender, orange-yellow needles, m. p. 147°; *acetoacetyl*-m-*aminoazotoluene*: orange, opalescent scales, m. p. 133—134°; *acetoacetyl*-4′-*chloro*-4-*aminoazobenzene*: slender, orange-yellow, felted needles, m. p. 188°; *acetoacetyl*-3′-*nitro*-4-*aminoazobenzene*: slender, orange-yellow, felted needles, m. p. 138° (decomp.); *acetoacetyl*-4′-*nitro*-4-*aminoazobenzene*: orange-red, lustrous scales, m. p. 190—191° (decomp.); *acetoacetyl*-4-*aminoazoxybenzene*: small, pale yellow rods, m. p. 138° (decomp.); *acetoacetyl*-4′-*amino*-2′-*methylbenzeneazo*-2-*naphthalene*: orange-yellow, spherical aggregates, m. p. 153—154°; *acetoacetyl*-4′-*aminobenzeneazo*-p-*cresol*: clusters of orange-yellow needles, m. p. 165°. W. T. K. B.

Dimorphism of Diphenylarsenious Chloride (Diphenylchloroarsine). C. S. Gibson and D. C. Vining (*J. Chem. Soc.*, 1924, **125**, 909—911).—Diphenylarsenious chloride (b. p. 178·6°/10 mm.) crystallises in two forms. The unstable modification, obtained by spontaneous crystallisation of freshly redistilled material, or by heating the stable form at 130° and cooling under "aseptic" conditions, forms needles, m. p. 18·2—18·4°, whilst the stable modification forms rhombic, biaxial crystals, m. p. 38·7—38·9°. [Cf. T., 1920, **117**, 777, 1447.] W. A. S.

Organo Derivatives of Bismuth. VII. Iodo and Nitro Derivatives of Triphenylbismuthine. J. F. Wilkinson and F. Challenger (*J. Chem. Soc.*, 1924, **125**, 854—864).—The red substance obtained by Challenger and Allpress (T., 1915, **107**, 17) consists mainly of phenyldi-iodobismuthine. *Triphenylbismuthine di-iodide*, Ph_3BiI_2, seems to be formed by direct union of triphenylbismuthine and iodine in ether solution at —78°, but decomposes at the ordinary temperature, giving the red solid. Triphenylbismuthine reacts with cyanogen bromide at 120°, giving diphenylbromobismuthine, bismuth oxybromide, and benzonitrile, whilst with cyanogen chloride scarcely any action takes place. This is in remarkable contrast to the action with cyanogen iodide (Challenger and Allpress, *loc. cit.*). Triphenylstibine and cyanogen iodide yield, presumably by interaction with moisture, in cold ether solution, *triphenylstibine hydroxyiodide*, $Ph_3Sb(OH)I$, m. p. 196°; triphenylarsine and triphenylphosphine gave, with the same reagent, what appeared to be similar additive compounds which decomposed on contact with water (cf. Steinkopf and others, A., 1922, i, 72). A nitric–sulphuric acid mixture at −15°, or fuming nitric acid at its melting point, completely disrupts triphenylbismuthine, giving *m*-dinitrobenzene as the organic product; with benzoyl nitrate, however, a *dinitrate*, $Ph_3Bi(O\cdot NO_2)_2$, was obtained; *tri*-p-*chlorophenylbismuthine dinitrate*, m. p. 163—165°, was obtained in a similar way. Triphenylbismuthine dinitrate is converted by cold nitric acid (*d* 1·52), into, according to conditions, a *mononitro* derivative, convertible into an unstable *dichloride*, m. p. 105—110°; a *dinitro* derivative, yielding a *dichloride*, m. p. 136° (decomp.); a *tetranitro* derivative, convertible into the dichloride, m. p. 146°, which when heated until it decomposes gives *m*-chloronitrobenzene, the presumption being therefore that one nitro group in the bismuthine is in the meta-position (cf. Gillmeister, A., 1898, i, 138). *Tetranitrotriphenylbismuthine dihydroxide* was also obtained as an insoluble yellow powder, m. p. 108° (decomp.); boiled with alcohol it gives trinitrotriphenylbismuthine(?). Lastly, *hexanitrotriphenylbismuthine dinitrate* was obtained and converted into a *dichloride*, m. p. 148—149°. W. A. S.

Action of Inorganic Halides on Organo-metallic Compounds. F. CHALLENGER and F. PRITCHARD (*J. Chem. Soc.*, 1924, **125**, 864—875).—A general discussion of earlier work (T., 1922, **121**, 104; cf. also Goddard and others, *ibid.*, 1923, **123**, 1163, etc.) and the following new observations. *Tri-α-naphthylstibine*, m. p. 218°, from antimony trichloride and magnesium α-naphthyl bromide, gives a *dichloride*, m. p. 260°, and a yellow *dibromide*, m. p. 229° (decomp.). *Tri*-m-*tolylbismuthine dibromide* has m. p. 92°. Although tri-*m*-tolylarsine may be obtained in a similar way from the appropriate Grignard reagent, *tri*-m-*tolylstibine hydroxychloride*, m. p. 209°, was the only product obtained by treating antimony trichloride with magnesium *m*-tolyl bromide. Triphenylstibine and phosphorus trichloride interact in the cold to give mainly triphenylstibine dichloride; triphenylarsine only reacts with the same reagent at 160°, and then incompletely, yielding diphenylchloroarsine; triphenylphosphine gives the dichloride and decomposition products. Arsenic trichloride and triphenylstibine at 80° yield triphenylstibine dichloride and a little arsenic. Antimony trichloride and triphenylarsine form an additive *compound*, m. p. 78°. The same reagent with triphenylphosphine produces a similar *compound*, m. p. 96°. Triphenylphosphine forms analogous compounds with arsenic trichloride [product has m. p. about 100° (decomp.) and a little arsenic separated] and with bismuth chloride (m. p. 100—105°). The latter, heated at 270° and treated with water, gave metallic bismuth and triphenylphosphine oxide. Triphenylbismuthine and stannic chloride also form an additive compound. Triphenyl-bismuthine and -stibine react to some extent with silicon tetrachloride, giving diphenylchlorobismuthine and triphenylstibine dichloride, respectively; triphenylarsine does not react. Titanium tetrachloride and triphenylbismuthine form a red compound and eventually yield diphenylchlorobismuthine; triphenylstibine gives only the dichloride, whilst triphenylarsine gives an unstable additive product. Attempts to prepare organic titanium compounds by interaction of titanium tetrachloride and magnesium phenyl bromide failed. W. A. S.

Fractionation of Gelatin by Extraction with Alcohol and Precipitation with Aluminium Hydroxide and Barium Chloride. M. A. Rakusin (*Chem.-Ztg.*, 1924, **48**, 249—250).—A sample of commercial "*Gelatina albissima*" was extracted with 95% alcohol, and the extract and the residue were investigated by precipitation with 10% aluminium hydroxide, the filtrate being precipitated with barium chloride. The various fractions were tested by the biuret, Ostromisslenski, and Molisch reactions, and and the composition of the gelatin is given as follows: free amino compounds, 0·50%; free carbohydrates, 0·96%; biuret complex, 49·27%; combined carbohydrates, 23·77%; combined chondroitin–sulphuric acid, 25·50%. The distribution of the mineral matter (3·29%) is uncertain. All the sulphur present in gelatin is combined in the form of chondroitin–sulphuric acid, which contains 5·71% of sulphur. Gelatin is therefore not an individual chemical substance, and gelatins obtained from different raw materials may have different properties. H. C. R.

Gelatin-sulphuric Acid and Casein-sulphuric Acid. J. Hatano (*Biochem. Z.*, 1924, **145**, 182—185).—By the action on gelatin and casein, in the presence of pyridine, of chlorosulphonic acid dissolved in dry chloroform, stable sulphates of these proteins are obtained. The preparation of gelatin sulphate obtained contained 1·7% of sulphur against 0·35% in the original gelatin, whilst casein sulphate preparations contained 0·84% and 1·38% of sulphur as compared with 0·62% in the original protein. J. P.

Products of Prolonged Tryptic Digestion of Casein. S. Fränkel, H. Gallia, A. Liebster, and S. Rosen (*Biochem. Z.*, 1924, **145**, 225—241).—After prolonged hydrolysis (2 months) of casein, the following products have been isolated: *d*-tyrosine anhydride, *d*-tryptophan anhydride, *d*-leucine anhydride, and histidine anhydride. The first three dextrorotatory anhydrides are supposed to arise from the lævorotatory amino-acids by the successive actions of the enzymes waldenase—bringing about an optical inversion—and anhydrase. In addition *d*-alanine, *d*-glutamic acid, *l*-oxyproline, *l*-serine, and *d*-valine were obtained, in part as such, and in part as the racemic forms. *l*-Proline, $[\alpha]_D^{12}$ $-74{\cdot}08°$ in water, *d*-*iso*leucine, $[\alpha]_D^{12}$ $+12{\cdot}77°$ in water, and *l*-aspartic acid were isolated in the unchanged condition, whilst glycine was partly converted into methylamine by the action of a decarboxylase. In the course of such prolonged hydrolysis, leucine is converted into the anhydride whilst *iso*leucine remains unchanged (cf. also A., 1922, i, 184; 1923, i, 398). J. P.

Protein Coagulation in Drops. IV. Influence of the Nature of the Proteins and Precipitants on the Precipitate. L. Cikánek, J. Havlík, and F. Kubánek (*Biochem. Z.*, 1924, **145**, 98—103).—The influence of a large number of substances on the coagulation of serum proteins has been studied, using the Bečka drop method. The presence in the precipitant of halogens, hydroxyl, sulphonyl, and nitro groups increases the precipitating action, whilst amino groups lower it. The precipitating powers of the aliphatic alcohols decrease with increase in the number of hydroxyl groups. With certain solutions of sodium sulphide, potassium hydroxide, and potassium cyanide, the albumin, but not the globulin, fraction is precipitated, whilst the reverse result is obtained with solutions of copper sulphate, cadmium nitrate, aluminium chloride, and disodium hydrogen phosphate. Certain pathological horse sera show a characteristic behaviour on precipitation with ferrous sulphate, pyrogallol, and tannin. J. P.

Influence of Hydrolysis on the Capacity of Proteins to Bind Acids and Bases. T. B. Robertson (*Austral. J. Exp. Biol.*, 1924, **1**, 31—37).—The ratio, equivalents of acid or base bound/equivalents of free amino-nitrogen, has been determined for casein and gelatin before and after hydrolysis by trypsin at p_H 2·0, 8·2, and 10·5. Except for gelatin at p_H 10·5, the ratio decreases as a result of hydrolysis. It is concluded, therefore, that the predominant method of union of proteins with acids and bases is through internal –CO·NH– groups rather than through free amino or carbonyl groups. O. O.

Halogenated Proteins. I. Bromo-ovalbumin. A. J. J. Vandevelde (*Rec. trav. chim.*, 1924, **43**, 158—162).—The action of bromine dissolved in carbon tetrachloride on some proteins in the form of a dry powder afforded bromo derivatives of higher halogen content than previously recorded. This is stated to be due to the fact that secondary reactions brought about by the presence of water were obviated. The following bromo derivatives (hygroscopic, orange-coloured powders of penetrating odour) are described: *Bromo-ovoprotein A*, soluble in water, yielding a strongly acid solution in which 87·1% of the total bromine is in the form of hydrobromic acid. At 100°, the substance loses hydrogen bromide to give *bromo-ovoprotein C*, which also yields an acid solution. Its colour, however, prevents it being examined with a coloured indicator. On dissolving the first-named substance in *N*-sodium hydroxide and then acidifying with acetic acid, a precipitate of *bromo-ovoprotein S* is formed. The percentages of bromine in these three substances are 37·5, 31·48, and 4·73, respectively. H. J. E.

Protein Phytotoxins, with Special Reference to the New "Modeccin." H. H. Green and P. Kamerman (*J. S. Afr. Chem. Inst.*, 1924, **7**, 3—5).—The roots of *Modecca digitata* (more correctly, *Adenia digitata*) contain a highly poisonous phytotoxin to which the name *modeccin* has been given; the fatal dose is

0·0005 mg. per kg. of body-weight, when injected intravenously or subcutaneously. In its general properties the substance resembles the other known phytotoxins, namely, ricin (from *Ricinus communis*), abrin (from *Abrus precatorius*), crotin (from *Croton tiglium*), robin (from *Robinia pseudacacia*), and curcin (from *Jatropha curcus*); all are stable up to about 70°, but destroyed rapidly at 100°. They are insoluble in 60% alcohol and are precipitated by ammonium sulphate and other salts. Modeccin resists hydrolysis by pepsin or trypsin for 3 days at 37°, but is destroyed by trypsin in 14 days; it does not possess hæmagglutinative properties and in this respect differs from ricin. W. P. S.

Protein Studies. III. Decomposition of Silk Fibroin by Fermentation. F. WESSELY.—(See i, 696.)

Biochemistry.

Effect of Salts of Calcium, Sodium, and Potassium on Respiratory Exchanges. I. Effect of Parenteral Administration of these Salts. W. ARNOLDI and J. FERBER (*Z. klin. Med.*, 1923, **97**, 208—216; from *Chem. Zentr.*, 1924, i, 494).—Injection of salts of calcium, sodium, and potassium produced increased utilisation of oxygen and diminution in respiratory quotient and the output of carbon dioxide in humans. Respiration within the tissues was increased. G. W. R.

Catalytic Action of Blood. L. WALLING and O. O. STOLAND (*Amer. J. Physiol.*, 1923, **66**, 503—518).—Blood catalase is accurately determined by reaction at p_H 8·9, 22°, for 0·5 hour; it is destroyed above 47° and is only slightly affected at 0°. In acid hydrogen peroxide at 22° it is apparently destroyed and its action complete in 10 minutes; with optimum alkalinity it acts for 3 hours or more. Sodium chloride (0·9%) in acid hydrogen peroxide increases, and in alkaline retards, the catalytic effect of blood.
CHEMICAL ABSTRACTS.

Influence of Rarefied Air on the Gaseous Metabolism of the Blood. A. LOEWY and J. FÖRSTER (*Biochem. Z.*, 1924, **145**, 318—323).—The blood of rabbits which had been kept under diminished pressure (430—460 mm.) for 24 to 33 hours showed a greater oxygen consumption than that of normal rabbits. The average figures found per 100 c.c. of blood per hour were 5·272 c.c. in the former and 2·733 c.c. in the latter case. J. P.

Cell Volume and Electrical Conductivity of Blood. H. C. GRAM (*J. Biol. Chem.*, 1924, **59**, 33—40).—The conductivity of whole blood and of serum, and the cell volume, were measured. An empirical curve has been obtained from which the cell volu may be read, if the ratio of the conductivity of the whole blood to that of the serum is known. W. O. K.

Rarefied Air and Blood Regeneration by "Hæmopoietins." J. Förster (*Biochem. Z.*, 1924, **145**, 309—317).—Serum from rabbits which had been kept in atmospheres at a pressure of 410 to 480 mm. for 1—2 days injected into rabbits rendered anæmic by bleeding, produced an increase in the rate at which the number of the red blood-corpuscles returned to the normal value. Normal sera and the proteins of milk did not produce this effect, which is ascribed to the production in the bone marrow, under the stimulus of the diminished pressure, of active substances—" hæmopoietins " (Carnot and Deflandre, *Compt. rend.*, 1906, **143**, 384)—which then find their way into the blood-stream. J. P.

Ultrafiltration of Blood Serum and Cerebrospinal Fluid. G. Egerer-Seham (*J. Lab. Clin. Med.*, 1923, **8**, 818—824).—A new apparatus is described. The ammonium sulphate globulin test is negative in the majority of ultrafiltrates of normal blood serum. The ultrafiltrates of non-syphilitic and syphilitic blood give a reduction of the colloidal gold solution in almost all cases. The ultrafiltrates of normal cerebrospinal fluid give no colloidal gold curve. The reduction of colloidal gold solution by ultrafiltrates from syphilitic spinal fluids seems to vary with the quantity of the substance reducing the colloidal gold solution present in the original spinal fluid. The substance giving the Wassermann reaction in syphilitic blood does not seem to be ultrafiltrable.

Chemical Abstracts.

Calcium-ion Concentration of Blood Plasma. E. J. Bigwood (*Bull. Soc. Chim. biol.*, 1924, **6**, 118—141).—In 20 normal subjects the calcium-ion concentration varied from 22 to 28 mg. per litre of venous blood plasma. The individual variations in any one subject are closely parallel to the variations in p_{H}, increasing with increasing acidity and *vice versâ*. Such a parallelism does not exist between the calcium-ion and bicarbonate-ion concentrations. J. P.

Effect of Fasting (and Re-feeding) on the Calcium and Inorganic Phosphorus in Blood Serums of Normal and Rachitic Rats. A. W. Cavins (*J. Biol. Chem.*, 1924, **59**, 237—242).—After fasting, the subnormal quantities of inorganic phosphorus present in the serum of rachitic rats increased approximately to normal, and the rickets healed concurrently. In the case of normal rats, there was no similar rise in the inorganic phosphorus in the serum after fasting. W. O. K.

Dynamics of Phosphoric Acid in the Blood. H. Lawaczeck (*Biochem. Z.*, 1924, **145**, 351—371).—The free phosphoric acid of whole blood was found to vary between 7·8 and 18·2 mg.%. When the blood was kept at or below body temperature part of the inorganic was converted into organic phosphate and this conversion was increased by the passage of air or hydrogen through the blood, but it did not occur if the blood had been previously warmed at 44—45°. The reverse conversion of organic into inorganic phosphate resulted from passing carbon dioxide. The reversible interconversion: inorganic $\rightleftarrows$ organic phosphate was found to proceed towards the right in the presence of phosphates, bicarbonate, and calcium, and towards the left in the presence of chlorides, water (hæmolysis), potassium, and sodium, but the cations mentioned were active only in hæmolysed blood. Both inorganic and organic phosphorus compounds passed from the serum into the corpuscles, and *vice versâ*.

The phosphates taking part in the above changes are acid-soluble, but hexosephosphate, which appears to be a product of the synthetic phase of the reaction, is not subject to the reverse hydrolytic change. J. P.

Proteins of Immune Sera, especially the Ratio of Globulin to Albumin (Protein Index). S. Bächer and M. M. Kosian (*Biochem. Z.*, 1924, **145**, 324—343).—An investigation of the amounts of protein precipitable from various normal and immune sera by one-third and one-half saturation with ammonium sulphate. Wide differences exist in the values obtained from the same types of sera from different animals, whilst old sera have a higher protein index than fresh sera and are thus regarded as more labile. Diphtheria sera (horse) show a higher total protein content than the normal, and absolute and relative increases in globulin, notably in pseudoglobulin, and decreases in albumin. During immunisation the lability of horse sera progressively increases, but this is not directly related to the formation of antitoxin. Immunisation of the horse against toxins other than diphtheria does not produce analogous results, nor does diphtheria toxin produce the same effects when injected into oxen. The increased lability of the proteins of old sera is associated with a similar alteration in the ease with which the antitoxin may be salted out with ammonium sulphate. J. P.

Action of Thrombin. IX. Blood Clotting. E. Wöhlisch (*Biochem. Z.*, 1924, **145**, 279—285).—The observation of Stuber and Sano (A., 1923, i, 410) that thrombin prepared by Schmidt's method, when separated from a solution of fibrinogen by a semi-permeable membrane, causes the fibrinogen to clot, was not confirmed when proper controls were employed. The views of these authors (*loc. cit.*) regarding the difference between the thrombin of fresh serum and that precipitated by alcohol according to Schmidt's process are not supported. J. P.

Nature of the Antihæmolytic Property of Heated Sera. G. Milkovitch (*Compt. rend. Soc. Biol.*, 1923, **89**, 877—879; from *Chem. Zentr.*, 1924, i, 356).—Hæmolysis is conditioned, not simply by the presence of a hæmolytic agent, but also by certain chemical factors, in particular the reaction, which must be to a certain degree alkaline. From experiments with human sera heated at

56° it is concluded that the presence of a specific "antihæmolysin" is improbable and that heating simply results in the production of chemical conditions unfavourable to hæmolysis. G. W. R.

Coagglutinating and Precipitating Action of Ricin. G. DI MACCO (*Z. Immunit.*, 1923, **38**, I, 467—488; from *Chem. Zentr.*, 1924, i, 493—494).—In addition to the direct agglutinative effect of ricin on certain blood-corpuscles, agglutination with corpuscles on which it cannot by itself exert any action, can be produced in the presence of serum from other animals. This coagglutination is not shown when ricin is first allowed to react with the serum in the absence of blood-corpuscles. Coagglutination is related to the precipitating action of ricin; it is considered to be physico-chemical in nature. G. W. R.

Precipitin Reactions of a Crystalline Globulin from Human Urine. H. S. EVERETT, S. BAYNE-JONES, and D. W. WILSON.—(See ii, 432.)

Potassium Fluoride as Preservative for Blood. R. H. MAJOR (*J. Amer. Med. Assoc.*, 1923, **81**, 1952).—In the absence of bacteria, clotting is prevented, and the sugar and carbon dioxide tension are unchanged during 7 days when potassium fluoride is added to blood. CHEMICAL ABSTRACTS.

Use of Formaldehyde for the Preservation of Blood Specimens. J. C. BOCK (*J. Biol. Chem.*, 1924, **59**, 73—76; cf. *ibid.*, 1920, **44**, 203).—The use of formaldehyde for preservation of blood for determinations of sugar by the method of Folin and Wu is inadvisable, as five of the six samples of formalin tested gave rise to markedly high results. W. O. K.

Animal Calorimetry. XXIV. Oxidation of Mixtures of Carbohydrates and Fat. A Correction. G. LUSK (*J. Biol. Chem.*, 1924, **59**, 41—42).—Corrections are given of errors in the standard table of Luntze and Schumberg ("Studien zu einer Physiologie des Marsches," Berlin, 1901, 361), showing the caloric value of 1 litre of oxygen used to oxidise mixtures of carbohydrates and fats. W. O. K.

Clinical Calorimetry. XXXV. A Graphical Representation of the Respiratory Quotient and the Percentage of Calories from Protein, Fat, and Carbohydrate. E. F. DU BOIS (*J. Biol. Chem.*, 1924, **59**, 43—49).—Graphs have been constructed from which it is possible to determine rapidly the number of calories produced by each litre of oxygen, knowing the total respiratory quotient and the percentage of calories furnished by protein. W. O. K.

Clinical Calorimetry. XXXVI. A Graphic Method of Determining certain Numerical Factors in Metabolism. A. M. MICHAELIS (*J. Biol. Chem.*, 1924, **59**, 51—58).—A graph is given from which it is possible to determine easily the total calories produced when 1 litre of oxygen is used in the combustion of a mixture of fats, proteins, and carbohydrates, from a knowledge of the urinary nitrogen, the total oxygen consumed, and the total respiratory quotient. From another graph, the percentage of calories derived from protein, fat, and carbohydrate, and that of oxygen used in the oxidation of each, may be read. W. O. K.

Thermochemistry of Protein Behaviour. J. H. MATHEWS and B. W. ROWLAND (*Colloid Symposium Monograph, Univ. Wisconsin,* 1923, 227—243).—Fixed amounts of 0·5*N*-hydrochloric acid were added to gelatin solutions of varying concentrations at 40° and the thermal change was recorded in Browne's adiabatic calorimeter. When in concentration greater than about 2%, gelatin containing 1·3% of ash shows markedly different results from ash-free isoelectric gelatin. Collateral experiments are described with gelatin and glycine. CHEMICAL ABSTRACTS.

Formation in the Injured Liver of a Compound Similar to Dextrose but Unsuitable for the Organism. VARELA and RUBINO (*Arch. exp. Path. Pharm.*, 1924, **101**, 316—334).—The occurrence of hypoglycæmia or of abnormally low hyperglycæmia after the oral administration of 10—20 g. of dextrose or lævulose is taken as an indication of the presence of a sugar unsuitable for utilisation. In certain diseases of the liver, this appears to obtain. It is suggested that the formation of glycogen does not involve merely the polymerisation of dextrose, but that there is a complex assimilation process. W. O. K.

Stimulus of Food on Intermediary Metabolic Processes. I. W. LAUFBERGER and J. A. ŠEFČÍK (*Biochem. Z.*, 1924, **145**, 274—278).—The oral administration of peptone or egg-albumin to rabbits produced a hyperglycæmia within 5 minutes. Mechanical stimulation of the gastric mucous membrane or the administration of olive oil had no influence on the blood-sugar. J. P.

Preparation of Insulin. N. F. FISCHER (*Amer. J. Physiol.*, 1923, **67**, 57—64).—The method of Doisy, Somogyi, and Shaffer (*J. Biol. Chem.*, 1923, **55**, xxi) is modified by effecting the final precipitation in two stages, with 1 and 8 volumes of alcohol, respectively. The first fraction is toxic, and produces a rise in the blood-sugar; the second is active, and of a potency which is the greater the smaller the amount of toxic substance present. Pancreas from old cows yielded only 100 units of insulin per kg., whilst that from calves yielded 1000 units. A. A. E.

Insulin-like Substance in the Kidney, Spleen, and Skeletal Muscle. J. S. ASHBY (*Amer. J. Physiol.*, 1923, **67**, 77—82).—A substance extracted from the kidney, spleen, and muscle of normal dogs and cattle, after the removal of the "toxic fraction," behaved similarly to insulin in producing hypoglycæmia in rabbits. Hypoglycæmia produced by the kidney extract was maintained for the unusually long period of at least 24 hours. A. A. E.

Amount of Available Insulin in the Pancreas of Domestic Animals. F. Fenger and R. S. Wilson (*J. Biol. Chem.*, 1924, **59**, 83—90).—The average yield of insulin from 1 kg. of fresh pancreas of cattle, sheep, or pig was from 1500 to 2200 rabbit units. The methods of purification and standardisation of the insulin are described in detail. W. O. K.

Disposal of Fat in the Organism. F. Köszeg (*Arch. exp. Path. Pharm.*, 1924, **101**, 305—315).—Iodipin (Merck), a fat containing iodine, was introduced in an emulsified form into the jugular vein of a dog. The quantities of iodine, up to about 2% of the weight of tissue, accumulated in the lung, were larger than was found in the liver or spleen. These results lend support to the view that the lung is active in the removal of fat from the blood-stream. W. O. K.

Autolysis. X. The Autolysis of Muscle. K. K. Chen and H. C. Bradley (*J. Biol. Chem.*, 1924, **59**, 151—164).—The rate of autolysis of the muscles of warm-blooded animals, as measured by the production of amino-acids not precipitated by trichloroacetic acid, is at a maximum at p_H 4·5—5·0. This agrees with the fact that *in vivo* atrophy of muscle-tissues follows conditions leading to an acidosis in the muscle-cells. In warm-blooded animals, there appears to be a relation between the activity and pigmentation of the muscle and the degree of autolysis, and similarly in the case of fish-muscle, the degree of autolysis appears to be determined by the activity of the muscles. In the molluscs examined, autolysis is slight and practically unaffected by reaction. W. O. K.

Amino-acids in Nutrition. VI. Nature of the Supplementary Value of Protein-free Milk to the Total Proteins of the Milk. VII. Cause of Nutritive Inadequacy of the Proteins of the Georgia Velvet Bean (*Stilzilobium Deeringianum*). B. Sure (*J. Metabolic Res.*, 1923, **3**, 373—382, 383—391).—VI. The effect is attributed to cystine or some other organic sulphur compound which may be transformed into cystine, and to traces of tyrosine in addition.

VII. The inadequacy is due to indigestibility and to deficiency of amino-acids, the latter being remedied by the addition to the diet of casein and cystine. Chemical Abstracts.

Metabolism of Sulphur. VI. Oxidation of Cystine in the Animal Organism. II. H. B. Lewis, H. Updegraff, and D. A. McGinty (*J. Biol. Chem.*, 1924, **59**, 59—71).—The sulphur in dibenzoylcystine which has been subcutaneously injected into rabbits is not oxidised, but as in the case of phenyluraminocystine (Lewis and McGinty, *ibid.*, 1922, **50**, 303; **53**, 349) it is partly reduced to form the sulphydryl group before excretion in the urine. When dibenzoylcystine is administered orally, a part of the sulphur is oxidised, but this is probably because the compound is partly hydrolysed into benzoic acid and cystine in the alimentary canal. W. O. K.

Substitution of Taurine for Cystine in the Diet of Mice. M. L. Mitchell (*Austral. J. Exp. Biol.*, 1924, **1**, 5—9).—That taurine can replace cystine to a considerable extent is suggested by the fact that the addition of either to a cystine-deficient diet produces growth which does not take place otherwise, and ceases immediately the taurine or the cystine is removed. O. O.

Metabolism of Benzoic Acid in the Human Organism. J. Neuberg (*Biochem. Z.*, 1924, **145**, 249—273).—After the administration of 10 to 15 grams of sodium benzoate to human subjects with normal or impaired kidney functions, no free benzoic acid was found in the urine. The sodium benzoate appears in the urine, not only as hippuric acid (90%), but also as (possibly) benzoylglycuronic acid (10%). It is concluded that methods of determining hippuric acid based on the determination of the benzoic acid freed by hydrolysis give results which are too high. J. P.

Nutrition and Growth on Diets Highly Deficient or Entirely Lacking in Preformed Carbohydrates. T. B. Osborne and L. B. Mendel [with H. C. Cannon] (*J. Biol. Chem.*, 1924, **59**, 13—32).—Rats fed on a diet composed of protein, with varying proportions of fat, inorganic salts, and some source of vitamins, but containing no preformed carbohydrates, showed in many instances good growth, although, as a rule, the male rats did not attain weights greater than about 250 g. W. O. K.

Vitamin Potency of Cod-liver Oil. A. D. Holmes (*J. Metabolic Res.*, 1923, **3**, 393; cf. *ibid.*, 1922, **2**, 113, 361).—The liver oil of emaciated cod caught in March has not so high a vitamin-*A* potency as that from well-nourished fish caught in later seasons. Chemical Abstracts.

Experimental Rickets. XXIV. Effect of certain Extracts of Plant Tissues on Florid Rickets. P. G. Shipley, E. M. Kinney, and E. V. McCollum (*J. Biol. Chem.*, 1924, **59**, 165—175).—Ether, alcohol, and water extract from lucerne leaves a substance which cures rickets in rats. Lucerne, extracted by ether, does not induce healing. Ether extracts an antirachitic vitamin from clover blossom, but, on the other hand, extracts of dry spinach, Brussels sprouts, cabbage, celery, tomato, and sweet potato were without antirachitic effect. W. O. K.

Experimental Rickets. XXV. Antirachitic Effect of certain Oils. P. G. Shipley, E. M. Kinney, and E. V. McCollum (*J. Biol. Chem.*, 1924, **59**, 177—182).—The following oils have no antirachitic effect: oil of sandalwood, oil of lemon, oil of orange-peel, oil of palm, fraction of butter fat insoluble in alcohol, Japan wax, oil of spice, oil of fennel seed, spermaceti, and sperm oil. Oil of cloves and the alcoholic extract of butter fat contain antirachitic vitamin. W. O. K.

Value of Bezssonoff's Reaction for indicating the Presence of Vitamin-*C* in the Juice of Sauerkraut. P. E. Wedgwood and F. L. Ford (*Bull. Soc. Chim. biol.*, 1924, **6**, 217).—A sample of the juice of sauerkraut which gave a blue coloration with Bezssonoff's reagent (*ibid.*, 1923, **4**, 83) failed to protect guinea-pigs from scurvy. It is concluded that Bezssonoff's reagent is not an infallible indicator of vitamin-*C*. C. T. G.

Additional Requirement for the Test with the Reagent for Vitamin-*C*. N. BEZSSONOFF (*Bull. Soc. Chim. biol.*, 1924, **6**, 220). —A reply to Wedgwood and Ford (see preceding abstract). A blue coloration indicates the presence of vitamin-*C* only if the colour is intensified on heating the liquid for a short time. If the colour is reduced or disappears on heating, vitamin-*C* is absent. The maximum dose used by Wedgwood and Ford in their experiments on guinea-pigs is considered to be too small to prove that vitamin-*C* is absent. C. T. G.

Persistence of Vitamin-*C* in the Livers of Rats on a Scorbutic Ration. S. LEPKOVSKY and M. T. NELSON (*J. Biol. Chem.*, 1924, **59**, 91—96).—The livers of rats fed from soon after the time of weaning on a ration as far as possible free from vitamin-*C* contain marked quantities of this vitamin as shown by the effect on the growth of guinea-pigs fed on a diet free from vitamin-*C*. A second generation of rats also fed on a diet free from vitamin-*C* likewise showed no diminution of this vitamin in the liver. W. O. K.

Importance of Zinc on the Nutrition of Animals. Experiments on Mice. BERTRAND and BENZON (*Bull. Soc. Chim. biol.*, 1924, **6**, 203).—It was found impossible to remove all traces of zinc from natural food materials without also removing vitamin-*B*, with which the zinc appeared to be associated. A synthetic food, based on the composition of wheat, was therefore used. Mice receiving the synthetic food with the addition of an amount of zinc as sulphate equivalent to that present in a normal diet of wheat lived 25—50% longer than those receiving the synthetic food alone. In the absence of any supply of zinc in the food, the amount present at the beginning is retained throughout life, whilst, if zinc be given, the original amount present is about doubled. C. T. G.

Non-reciprocal Permeability. III. Non-reciprocal Permeability of Ions and of Colouring Matters. E. WERTHEIMER (*Pflüger's Archiv*, 1923, **200**, 354—365; from *Chem. Zentr.*, 1924, i, 346; cf. *Pflüger's Archiv*, 1923, **200**, 82).—The non-reciprocal permeability shown by the cuticular membrane of frogs is confined to sodium ions. Other cations pass equally freely in both directions. Anions are without influence. Colouring matters behave differently according as they are acidic or basic, the former passing the membrane in an inward direction and the latter in an outward direction. Some acidic and basic colouring matters can pass in either direction. The phenomena are influenced by the reactions on the inner and outer side of the membrane. By making use of non-reciprocal permeability, mixtures of colouring matters may be separated. G. W. R.

Radioactivity of Living Cells. A. NODON (*Compt. rend.*, 1924, **178**, 1101—1102).—The radioactivity of living cells has been demonstrated by photographic means. A sample of barium-radium sulphate, a living insect (*Pœcicoloris*), and a green leaf were confined separately in boxes so as to be able to affect a photographic plate, without coming into contact with the sensitive surface. After 20 hours' exposure, the radium salt gave a strong impression, the insect a more feeble impression, and the leaf a thin film. The activity indicated is of the same order as that indicated by electrometric measurements. [Cf. this vol., i, 347.]

A. B. H.

Coagulation and Structure of the Egg. J. AMAR (*Compt. rend.*, 1924, **178**, 803—805; cf. this vol., ii, 144).—Desiccation of birds' eggs over sulphuric acid showed that egg-white and egg-yolk contain 86% and 48% of water, respectively. Desiccation and re-hydration are completely reversible, unless structural changes (such as are caused by heating or by alcohol) intervene. The dried white contains spiraloid forms (insoluble albumin) in a homogeneous mass (soluble albumin). Sodium chloride does not cause the coagulation of the white or the yolk. The chlorides of potassium, magnesium, calcium, barium, and zinc effect coagulation to an increasing amount (in the order given). Sodium phosphate (present in the egg) hinders coagulation.

E. E. T.

Sugar in the Cerebrospinal Fluid. G. H. MOATES and J. J. KEEGAN (*J. Lab. Clin. Med.*, 1923, **8**, 825—828).—The normal range of cerebrospinal fluid sugar is 0·040—0·068%. The concentration is increased in most cases of epidemic encephalitis but decreased in infectious meningitis. There is no apparent relation between the sugar content of the cerebrospinal fluid and the Wassermann reaction, colloidal gold curve, cell count, globulin, or total protein. CHEMICAL ABSTRACTS.

Bile Secretions. IV. Colorimetric Determination of Bile Acids in Human Body Fluids. F. ROSENTHAL and F. LAUTERBACH.—(See ii, 431.)

Mechanism of Muscular Action. O. W. TIEGS (*Austral. J. Exp. Biol.*, 1924, **1**, 11—29).—It is considered that lactic acid is liberated from only one of the excitable membranes, and at the same time the other membrane must liberate a basic substance, hitherto unrecognised. When this happens, the processes constituting a muscle twitch must occur and their nature can be explained on a physico-chemical basis. O. O.

Alteration of the Constituents of Preserved Flesh. I. A. SMORODINZEV and A. N. ADOWA (*Z. physiol. Chem.*, 1924, **135**, 41—48).—Large quantities of salt solution were pumped into the aorta shortly after killing, and the extractive substances in the muscle-tissues examined after storage for 15 months. The creatinine content was the same as that of fresh flesh, whilst the creatine was reduced to one-fifth or one-tenth. The fact that there was no increase in the amount of methylguanidine suggests that this compound does exist in the tissues and is not necessarily the product of an oxidation occurring during the extraction of creatinine (cf. Ewins, A., 1916, i, 528). E. M. C.

Oxidising Power of the Nuclei of the Epithelium of the Renal Canaliculi of *Perca fluviatilis*. M. Manquat (*Compt. rend.*, 1924, **178**, 972—974).—The nuclei of the epithelial cells of the renal canaliculi of the perch appear to possess oxidising properties, since they become blue when indigo-carmine is injected into the alimentary canal, whereas the cytoplasm remains colourless. This phenomenon was not observed with any of the other species of fresh-water fish examined. T. H. P.

Venom of *Lachesis ammodytoides*. B. A. Houssay and J. Negrete (*Compt. rend. Soc. Biol.*, 1923, **89**, 751—753; from *Chem. Zentr.*, 1924, i, 491).—The venom of this Argentine snake is golden-yellow and contains 34—40% of water. It precipitates the anti-serum for *Lachesis alternatus*, but only slightly that for *Crotalus terrificus*. It has no amylolytic effect and does not attack neutral fats. A description of its physiological effects is given. G. W. R.

Excretion of Creatinine by the Kidneys. V. Cantinieaux (*Compt. rend. Soc. Biol.*, 1923, **89**, 848—851; from *Chem. Zentr.*, 1924, i, 358).—The amount of creatinine eliminated in the urine of healthy men is a function of the total creatinine (preformed creatinine + creatine) in the blood. The relationship is expressed according to Ambard's formula by the constant 0·07 for normal individuals. In cases of depressed renal activity there is a parallelism with the constant for urea. The formulæ of Austin, of Stillman, and of Van Slyke give similar results. No constant results are given when the amount of preformed creatinine in the blood alone is used in the above formulæ. G. W. R.

Electropy. VII. Excretion of Electropic Dyestuffs and Carbinols. L. Karczag and L. Paunz (*Biochem. Z.*, 1924, **145**, 345—350).—Electropic dyestuffs of the triphenylmethane group administered subcutaneously or intravenously to rabbits or guinea-pigs were found in the urine, bile, cerebrospinal fluid, aqueous humour of the eye, peritoneal exudate, and amniotic fluid as colourless carbinols. The less the dispersion of the dyestuff the more slowly is it excreted; the most highly dispersed dyestuffs are excreted by the kidney whilst less highly dispersed dyes are found in the bile. The electrostatic charge on the particles of the dyestuffs is of importance in their conversion and excretion. J. P.

Porphyrin Formation. I. O. Schumm (*Z. physiol. Chem.*, 1924, **133**, 308—320).—The increase in the porphyrin content of the fæces, associated with diet (A., 1923, i, 732), is considered as originating from a constituent of the flesh. The porphyrin prepared from rotting flesh has been examined spectroscopically; it differs from coproporphyrin, but appears to resemble closely the porphyrin prepared from blood by the author, and also that described by Kämmerer and Fischer (cf. Fischer and Schneller, A., 1923, i, 1244). Coproporphyrin could not be found in fresh beef or in frozen meat. O. O.

Correction of "Natural Porphyrins." III. O. Schumm (*Z. physiol. Chem.*, 1924, **133**, 298—307; cf. Fischer and Schneller, A., 1923, i, 1244).—Mainly polemical. The author claims priority in this work, and sees no reason to change the views put forward in his previous paper (A., 1923, i, 631). O. O.

Menstruation and the Choline Balance. E. Sieburg and W. Patzschke (*Z. ges. exp. Med.*, 1923, **36**, 324—343; from *Chem. Zentr.*, 1924, i, 572).—The choline content of the sweat was found to be 80—100 times normal and of the serum 2—15 times normal during menstruation. Intravenous injection of 0·5 g. of choline chloride in women resulted, in half the cases investigated, in a diminished rate of coagulation of the blood. G. W. R.

Relation of the Chemical Constitution of certain Organic Arsenical Compounds to their Action on the Optic Tract. A. G. Young and A. S. Loevenhart (*J. Pharm. Expt. Ther.*, 1924, **23**, 107—126).—Arsenical drugs with quinquevalent arsenic, such as atoxyl, arsacetin, and tryparsamide, frequently affect the optic tract and may produce blindness, whilst certain tervalent arsenic compounds, such as arsphenamine, do not have this effect. Sixteen arsenical compounds of similar constitution were tested by intravenous administration to rabbits, and it was found that the valency of the arsenic was not the most important factor. Optic lesions were produced by compounds containing an amino group or a substituted amino group in the para-position to the arsenic, but were not produced when the amino group was in the ortho- or meta-position. E. M. C.

Effect of Compounds Related to Hydrazine in Producing Anhydræmia and Experimental Anæmia. M. Bodansky (*J. Pharm. Expt. Ther.*, 1924, **23**, 127—132).—The destruction of red corpuscles by subcutaneous injection into dogs of certain hydrazine derivatives has been studied with a view to the experimental production of anæmia. Hydrazine gave a temporary increase in blood concentration (anhydræmia) followed by a slight anæmia. Phenylhydrazine, acetylphenylhydrazine, and *p*-bromophenylhydrazine produce rapid destruction of red corpuscles; methylphenylhydrazine and diphenylhydrazine have similar although less marked effects, whilst *s*-di*iso*propylhydrazine, hydrazobenzene, and 2 : 2′-azobispropane cause a moderate amount of destruction. Mild anæmias were produced in rabbits by azobenzene, azoxybenzene, diazobenzene, and aminoazobenzene; diphenylcarbazide and *p*-hydrazinobenzoic acid have no effect on the blood. Compounds which are especially destructive of liver-tissue were found most effective in producing anhydræmia. E. M. C.
